CONFECTION OF CASSIA, made by mixing cassia-pulp 100 Gm., syrup of violets 75 Gm., and sugar 20 Gm., evaporating to the consistence of a soft extract, and flavoring with a drop of oil of neroli, is known in France as *Casse cuite*.

Off. Prep.—*Confectio sennæ*, *U. S.*, *Br.*

Allied Drug.—**CERATONIA SILIQUA**, *Linné*.—*Fructus ceratoniae*, *Siliqua dulcis*.—*St. John's bread*, *E.*; *Carouges*, *Caroubes*, *Fr.*; *Johannisbrot*, *Karobe*, *G.*—This medium-sized evergreen tree grows in the basin of the Mediterranean, and bears purple-colored racemes of polygamous apetalous flowers. The fruit is 4 to 8 inches (10 to 20 Cm.) long, nearly 1 inch (25 Mm.) broad, about $\frac{1}{8}$ or $\frac{1}{4}$ inch (3 or 4 Mm.) thick, obtuse, linear, much flattened, and with somewhat elevated edges, causing the transverse section to be narrowly and obtusely rectangular. The epicarp is leathery, brown, glossy, finely striate, and encloses a light-brown softer sarcocarp of a pleasantly sweet taste. The seeds, six to twelve in number, are flattish ovate and polished brown, and are contained in separate transverse cells formed by the papery inner layer of the pericarp. The fruit contains 40 to 50 per cent. of cane- and grape-sugar, besides mucilage, protein compounds, a little tannin, and butyric acid, to which the odor is due. The presence of free butyric acid was observed by Redtenbacher (1846). *St. John's bread* is frequently used in Southern Europe as an addition to expectorant and demulcent medicines.

Medical Action and Uses.—Anciently used as a laxative to which special cooling virtues were attributed, and as a cleansing gargle for ulcerated sore throat, purging

castanea is still esteemed as a mild and certain *laxative*, tending to promote the secretion of bile. It gives a brownish or greenish tinge to the urine. It is seldom used alone, owing partly to its tendency to occasion colic and flatulence. With manna it forms an active but mild laxative, and in hot climates and seasons it is usefully associated with tamarinds or with mild salines, especially in the treatment of *bowel complaints*. As a laxative the *dose* is from 1 to 2 drachms (Gm. 4-8); as a purgative, 1 or 2 ounces. The sweet and acidulous pulp of the seeds of *Ceratonia siliqua* is used as a laxative in bronchitis and in the gastric and biliary derangements that are common in the south of Europe.

CASTANEA, U. S.—CHESTNUT-LEAVES.

Folia castaneæ.—*Feuilles de châtaignier, Feuilles de marronnier, Fr.; Kastanienblät-ter, G.*

The leaves of *Castanea vesca*, *Gaertner* (*C. vulgaris*, *Lamarck*, *C. sativa*, *Miller*, *Fagus Castanea*, *Linne*), collected in September or October while still green.

Nat. Ord.—Cupuliferae.

Origin.—A stately tree, 80 to 100 feet (24 to 30 M.) high, indigenous to Western Asia, Southern Europe, and to the United States from Maine to Michigan southward. The wood, though light, is very durable. The whitish staminate flowers, which appear in May and June, form slender, pendulous aments 6 to 8 inches (15 to 20 Cm.) long; the pistillate flowers form clusters of three or four in an ovoid involuere, which finally becomes globose and covered with sharp prickles, and encloses two or three one-seeded nuts. These *chestnuts* (*châtaignes, F.; Kastanien, Maronen, G.*) are flattish, hemispherical, or somewhat triangular, brown, glossy, silky-pubescent at one end, and contain a firm white embryo having a sweet taste. American chestnuts are smaller and sweeter than those of Southern Europe.

Description.—The leaves are from 6 to 10 inches (15 to 25 Cm.) long, about 2 inches (5 Cm.) wide, upon petioles less than 1 inch (25 Mm.) in length, oblong-lanceolate, acuminate, mucronate, sinuate-serrate, smooth throughout, shining above, neatly feather-veined beneath. The leaves of the American chestnut (*Cast. americana, Rafinesque*) differ from those of the Oriental only in being rather acute at the base. They are nearly inodorous and have a somewhat astringent taste. They should be collected in the fall, in September or October, while still green; on drying they lose from 50 to 60 per cent. in weight.

Constituents.—Chestnut-leaves examined by J. B. Turner (1879) and L. J. Steltzer (1880) were found to have the ordinary constituents of leaves—chlorophyll, fat, a little resin, gum, albumen, and extractive; the tannin, which gives a green-black precipitate with iron, was estimated at 9 per cent. by weighing the gelatin precipitate. The ash amounts to 5 or 6 per cent., and consists of carbonate, phosphate, and chloride of potassium, magnesium, calcium, and iron. The fruit contains nearly 50 per cent. of water, the remainder being starch 30 to 40, proteids 3 to 4, fat about 2, sugar $\frac{1}{2}$ to 1 or 2 per cent., some mucilaginous matter and organic acids, and in the integuments resin, tannin, and bitter principle.

Off. Prep.—*Extractum castaneæ fluidum, U. S.*

Allied Plant.—CASTANEA (*FAGUS, Linne*) *PUMILA, Michaux*, is indigenous to the United States, from Southern Pennsylvania and Ohio to Florida and Eastern Texas. It is shrubby, or in the Southern States a tree 40 or 50 feet (12 or 15 M.) high. The leaves are oblong or somewhat obovate, acute, pointedly serrate, and white-downy beneath. The prickly involuere contains a single ovoid, acute, and dark-brown nut, called *chinquapin*, which is smaller than the chestnut and very sweet. The bark, like that of the chestnut, is astringent.

Medical Action and Uses.—We are not acquainted with any experiments which denote the physiological operation of castanea, but, judging from its apparent action in *whooping cough*, its sedative influence upon the respiratory nerves may be inferred. In the disease just mentioned it appears to control the paroxysms in a remarkable manner, in some cases suspending them entirely after the lapse of a few days. It may be given without limit in the form of an infusion made with an ounce (Gm. 30) of the dried leaves in a pint of boiling water, or, more accurately, in the dose of from $\frac{1}{2}$ fluidrachm to 1 fluidrachm (Gm. 2-4) of the fluid extract every 3 or 4 hours. Its taste is not unpleasant, and its administration requires no special circumspection.

CASTOREUM, *Br.*, *P. G.*—CASTOR.*Castoréum*, Fr.; *Bibergeil*, G.

The dried preputial follicles and their secretion obtained from the beaver. *Castor Fiber*, Linné (*Castor americanus*, Cuvier, s. *C. canadensis*, Kuhl). and separated from the somewhat shorter and smaller oil-sacs which are frequently attached to them.

Class Mammalia. Order Rodentia.

Origin.—This animal inhabits the continents of the northern hemisphere between 33° and 68° N. lat., but is disappearing in the southern parts of those regions. It is from 2 to 2½ feet (60 to 75 Cm.) long, with horizontally-flattened tail, which is about 10 inches (25 Cm.) long and 3 to 4 inches (7 to 10 Cm.) wide, hairy at the base and scaly above. The head resembles that of a rat, with no canine teeth, but with two incisors, and on each side four molars in the upper and lower jaw. The fur consists of two kinds of hair—one rather bristly, the other denser and downy; its color is brown, but black, white, and spotted beavers are also met with. The feet have five toes, the anterior being short and close, the posterior longer and palmated; the hind feet are webbed close to the toes. Anus, genitals, and follicles communicate in both sexes with one canal or cavity located near the tail. In the male a pair of oil-sacs, containing the formerly official *axungia castoris*, terminates in the cloaca; the castor-sacs, located near the former, open by a common aperture in the preputial canal. The female has the castor-sacs below the os pubis on each side of the vagina. The European and Siberian beaver closely resembles the American in appearance and habits, but is somewhat larger and has a paler-colored fur.

The beaver feeds on roots and barks, and builds houses about 10 feet (3 M.) wide and 6 feet (1.8 M.) high, the entrance being under the water, the depth of which is increased by the building of dams composed of billets of wood and earth; in more densely-populated districts, where they are disturbed, the beavers burrow on the banks of rivers and creeks.

Description.—When fresh, castor-sacs are flesh-colored, soft, more or less pyriform; they are dried by being suspended over fire, when they become brown. They consist of four distinct coats: the outer one is cellular, resembles hog's bladder in texture, and encloses a fibrous layer, which is followed by a vascular, and this by an iridescent glandular coat, with many folds and numerous semilunar scales upon the inner surface, the whole being covered by a thin epithelium. According to E. H. Weber (1849), castor is mainly secreted by the prepuce of the penis and clitoris, but J. Fuchs (1881) states that it is altogether separated from glands contained in the inner coat of the sac. The contents of the recent follicles are an unctuous, yellowish, odorous mass, which, after drying, becomes brown and friable, but is not fusible. Castor is commercially distinguished by the countries from which it is obtained, the most highly valued being obtained from Russia and Siberia.

CASTOREUM SIBIRICUM, s. *Castoreum moscoviticum*, *rossicum*, *germanicum*, *europæum*. The sacs are oval or globular pyriform, united at the narrowed end in pairs, the contents of a dull rather light-brown color and a strong peculiar odor. The sacs vary in weight from about 3 to 8, or occasionally even 14, ounces, and if not too dry the two outer coats may be readily separated. This kind is mostly collected in Siberia and Eastern Russia, the sacs from Western Russia and Germany being usually smaller and rarer. It is now rarely met with in commerce.

CASTOREUM CANADENSE, s. *Castoreum americanum*, *anglicum*. This is the variety generally met with in commerce, and which alone is recognized by the British and German Pharmacopœias, but has been omitted from the U. S. P. 1880. The sacs are more elongated, flatter, and usually more wrinkled and folded, than those of the preceding; they vary from club-shaped to narrow pyriform, are united in pairs, mostly between 1 and 4 ounces (rarely 8 ounces) each in weight; the outer coats adhere pretty firmly; the contents are often slightly glossy; the odor is aromatic, but weaker than the preceding; the taste about the same, pungent, bitter, and rather nauseous.

Russian and American castor are distinguished from each other by the characters indi-

FIG. 58.

Castor Fiber, Linné: b, scales of the tail.

ated; the former yields 60 to 68 per cent. of its weight to alcohol, the latter between 45 and 50 per cent. The tincture of the former yields with much water a milky mixture, which becomes nearly clear on the addition of ammonia. The mixture obtained from the tincture of American castor is brownish, the precipitate being only partly soluble in ammonia.

Adulterations.—Castor is said to be occasionally adulterated with artificial mixtures of blood and earthy and resinous matters enclosed in some animal tissue; such substitution is easily detected by the absence of nearly all the characters described above.

Constituents.—The numerous older investigations have not thrown much light upon the composition of castor. The *volatile oil* of castor, present to the extent of 1 to 2 per cent., has the odor of that substance, and is of a pale-yellow color; according to Woehler (1844), it contains *carbolic acid*. The same chemist noticed also (1848) the presence of *salicin* and *benzoic acid*. Pereira (1851) believes the volatile oil to be mainly derived from the salicin, and observed that distilled castor-water gradually acquired the odor of salicyl-aldehyd (oil of *Spiraea ulmaria*). The bitter and acrid taste of castor is due to a dark-brown *resinous substance* which is insoluble in water and ether, but readily soluble in alcohol; it has not been further investigated. A peculiar crystalline body, *castorin*, was obtained by Bizio on cooling the strong alcoholic decoction. Valenciennes (1861) prepared it by boiling castor with milk of lime and treating the dried precipitate with hot alcohol; it forms colorless, readily fusible needles having a slight odor of castor and little taste; it volatilizes slowly with boiling water, is soluble in concentrated potassa, ether, benzin, and hot olive oil and oil of turpentine. Lehmann believes that the carbolic acid, if present, is obtained only from the smoke of the fire by which castor is dried; he found also *derivatives of bile*, *cholesterin*, and a *protein compound*, the last two of which had already been obtained by Brandes. The inorganic constituents are carbonates, with some phosphates and sulphates of calcium, magnesium, potassium, and ammonium. Pereira obtained from Canadian castor 3.6 per cent. of ash. Castor-sacs containing a large proportion of calcium carbonate have been sometimes met with, and are said to be obtained from diseased animals.

Off. Prep.—Tinctura castorei, Br., P. G.

Medical Action and Uses.—It seems doubtful whether castor, any more than musk, has a definite action upon the healthy nervous system, but there is just as little doubt that, like the other animal product just named, it is a stimulant to the nervous system disordered through exhaustion, direct or indirect. *Hysterical spasms*, those associated with *uterine colic*, *scanty menstruation*, and *tympanites*, and the muscular twitchings, tremblings, etc. which occur in the *typhoid state*, are palliated by this medicine. But for all purposes it is less efficient than musk, and scarcely superior to valerian, camphor, ammonia, ether, and some forms of alcohol. The *dose* of castor varies from 10 grains (Gm. 0.60) to ten times that amount, according to the strength of the preparation employed. The variable quality of the drug restricts its use.

CATALPA.—BEANTREE.

Catalpa, F., Fr., G.

Catalpa bignonioides, Walter, s. *Bignonia Catalpa*, Linné.

Nat. Ord.—Bignoniaceae.

Description.—The tree is indigenous to the southern portion of the United States from Georgia and Florida westward, and is cultivated or wild farther north. It attains a height of 30 to 50 feet (9 to 15 M.), produces a light, close-grained, and very durable wood, and has spreading branches, large heart-shaped leaves, and compound racemes of showy flowers, which have the calyx two-lipped, the corolla bell-shaped, white, and in the throat dotted with purple and yellow. The fruit is capsular, nearly cylindrical, about 12 inches (30 Cm.) long, longitudinally striate and two-celled, and contains numerous very thin, long, and flat seeds which are enclosed in a delicate silky envelope, prolonged at both ends into finely-fringed wings. The bark, fruit, and seeds have been employed. The bark is externally gray-brown, smooth, somewhat glossy, with numerous small circular warts; in the middle layer green, and in the thick, tangentially arranged bast-layer white, becoming yellowish on drying; the inner surface is smooth. The bark of the trunk is about $\frac{1}{4}$ inch (6 Mm.) thick, one-half consisting of the scaly cork, the other half of the bast-layer. It has a strongly bitter taste. The catalpa of the Western States is regarded as a distinct species, *Catalpa speciosa*, Warder; it is found in

Southern Indiana and Western Kentucky, westward and south-westward, and has a rather heavier but equally durable wood.

Constituents.—The bark was analyzed by E. A. Rau (1870), who ascertained the presence of tannin in it. On dissolving the ethereal extract of the alcoholic extract in diluted alcohol, and boiling with oxide of lead, the liquid retained an amorphous bitter principle in solution, and hot alcohol dissolved from the lead precipitate a principle having an intensely nauseous, bitter taste and crystallizing in micaceous scales, which were very soluble in ether, chloroform, and hot alcohol. Sugar and tasteless resin were also found.

Allied Plants.—*BIGNONIA CAPREOLATA*, *Linné*, a native of the Southern United States, is a tall, climbing shrub, with orange-colored, bell-shaped, and somewhat two-lipped flowers, which are about 2 inches (5 Cm.) long. The root and stem have been used in place of sarsaparilla. A transverse section of the stem shows the wood in the shape of a cross. This plant, like the closely-allied *Tecoma radicans*, *Jussieu*, which bears large scarlet flowers, is known as *trumpet creeper*.

Several East Indian species of *Bignonia* are medicinally employed in their native country.

Medical Action and Uses.—This tree is more ornamental than it is useful in medicine. The bark, indeed, is said to be vermifuge, the wood emetic, and the leaves emollient and anodyne, yet the emanations of the tree are reported to be poisonous. A decoction of the pods, and the dried seeds also, have been used with alleged advantage in chronic *brouchitis* and in nervous *asthma*, especially when associated with *senega*, of which latter statement there need be no serious doubt. The juice of the root is also stated to be an efficient local remedy for chronic serofulous *ophthalmia*.

“The root and vine of *Bignonia capreolata* in infusion or decoction answer the purpose of sarsaparilla. They are detergent and alterative, diuretic and sudorific, used in syphilis, chronic rheumatism, and in derangements arising from impurities of the blood” (Porcher, *Resources of the Southern Fields and Forests*).

CATAPLASMATA.—CATAPLASMS.

Poultices, E.; *Cataplasmes*, Fr.; *Umschläge*, *Bräuumschläge*, G.

These are topical applications, of a soft, pasty consistence which are prepared from coarse or fine powders, mixed with water, various solutions, or fixed oils. In this country the ingredients are usually furnished by the pharmacist, but the poultice is prepared for use at the patient's house.

CATAPLASMA CARBONIS, *Br.*—CHARCOAL POULTICE.

Cataplasme au charbon, Fr.; *Kohlenumschlag*, G.

Preparation.—Take of Wood Charcoal in powder $\frac{1}{2}$ ounce; Crumb of Bread 2 ounces; Linseed Meal $1\frac{1}{2}$ ounces; Boiling Water 10 fluidounces. Macerate the bread in the water for 10 minutes near the fire, then mix, and add the linseed meal gradually, stirring the ingredients, that a soft poultice may be formed. Mix with this half the charcoal, and sprinkle the remainder on the surface of the poultice.—*Br.*

Medical Uses.—Charcoal poultice is used as an emollient and disinfecting application to *gangrenous* and *fetid sores*.

CATAPLASMA CONII, *Br.*—HEMLOCK POULTICE.

Cataplasme avec la ciguë, Fr.; *Schierlingumschlag*, G.

Preparation.—Take of Hemlock-Leaf in powder 1 ounce; Linseed Meal 3 ounces; Boiling Water 10 fluidounces. Mix the hemlock and linseed meal, and add them to the water gradually, with constant stirring.—*Br.*

Medical Uses.—Hemlock poultice is employed especially to relieve the pain of *cancerous* and other *sores*. Extract of conium may be substituted for fresh hemlock-leaves in its preparation.

CATAPLASMA FERMENTI, *Br.*—YEAST POULTICE.

Cataplasme avec le levûre de bière, Fr.; *Hefenumschlag*, G.

Preparation.—Take of Beer Yeast 6 fluidounces; Wheaten Flour 14 ounces; Water

heated to 100° F. 6 fluidounces. Mix the yeast with the water, and stir in the flour. Place the mass near the fire till it rises.—*Br.*

The rising of the mass takes place in consequence of fermentation, which speedily commences, and whereby carbonic acid gas is formed.

Medical Uses.—Yeast poultice or fermenting poultice is of great service to unhealthy, and especially gangrenous, *ulcers*, whether of a cancerous nature or not, in preventing fetor and hastening the removal of devitalized tissues. Its activity is indicated by the pain it sometimes causes.

CATAPLASMA LINI, *Br.*—LINSEED POULTICE.

Cataplasma emolliens s. communis.—*Flaxseed poultice*, E.; *Cataplasme de farine de lin*, *Cataplasme simple (commun)*, Fr.; *Leinsamen-Umschlag*, G.

Preparation.—Take of Linseed Meal 4 ounces; Olive Oil $\frac{1}{2}$ fluidounce; Boiling Water 10 fluidounces. Mix the linseed meal gradually with the water, then add the oil with constant stirring.—*Br.*

The linseed meal of the British Pharmacopœia is the *cake meal* of American commerce; that is, the press-cake left after the expression of linseed oil and reduced to powder; hence the addition of olive oil in the above formula. By mixing equal parts of ground flaxseed and cake meal a mixture is obtained with about the same percentage of fat. Ground flaxseed is often used without admixture of other powders.

Medical Uses.—Linseed or flaxseed poultice is usually employed in hospital practice as an emollient and protective to *inflamed* and *painful parts*. Owing to its tendency to ferment, it is apt to occasion an eruption of vesicles or pustules, and more than any poultice to render the skin white, wrinkled, and sodden. To prevent these effects its surface should be covered with fresh lard, sweet oil, linseed oil, or glycerin, or else one or the other of these articles should be mixed with the poultice.

CATAPLASMA SINAPIS, *Br.*—MUSTARD POULTICE.

Sinapismus; *Cataplasma rubefaciens.*—*Sinapisme*, *Cataplasme de moutarde*, *Cataplasme rubéfiant*, Fr.; *Senfteig*, G.

Preparation.—Take of Mustard, in powder, 2 $\frac{1}{2}$ ounces; Linseed Meal 2 $\frac{1}{2}$ ounces; Boiling Water 10 fluidounces. Mix the linseed meal gradually with the water and add the mustard, with constant stirring.—*Br.*

Ground black mustard 200 Gm.; cold or tepid water sufficient to obtain a mass of the consistence of a poultice.—*F. Codex.*

The British Pharmacopœia evidently intends the powder of *white* mustard-seed to be used, though it does not specially indicate it. The French Codex very properly cautions us against the use of *hot* water, and also of vinegar, which prevent the formation of oil of mustard or lessen its amount.

Medical Uses.—This poultice is convenient for maintaining a moderately stimulant action upon the skin, and at the same time protecting it. It is very useful in local muscular *rheumatism*, in thoracic and abdominal *inflammations*, in *colic*, and for exerting a derivative action upon the feet in congestive affections of the *head*. The preparation and uses of the sinapism or mustard *plaster* are described under SINAPIS.

CATAPLASMA SODÆ CHLORATÆ, *Br.*—CHLORINE POULTICE.

Cataplasme chloriné, Fr.; *Chlornatron-Umschlag*, G.

Preparation.—Take of Solution of Chlorinated Soda 2 fluidounces; Linseed Meal 4 ounces; Boiling Water 8 fluidounces. Mix the linseed meal gradually with the water, and add the solution of chlorinated soda, with constant stirring.—*Br.*

Medical Uses.—Chlorine poultices are useful in the same cases in which yeast poultices are appropriate; that is to say, for correcting the fetor of foul and sloughing *ulcers* and for stimulating them to become more healthy.

CATARIA.—CATNEP.

Herba nepetæ s. catarixæ.—*Catmint*, E.; *Cataire*, *Chataire*, *Herbe aux chats*, *Menthe de chats*, Fr.; *Katzenminze*, *Katzenkraut*, G.

The leaves and tops of *Nepeta Cataria*, *Linneé*, s. *Cataria vulgaris*, *Moench*. Bentley and Trimen, *Med. Plants*, 209.

Nat. Ord.—*Labiatae*.

A perennial herbaceous plant 2 to 4 feet (0.6 to 1.2 M.) high, indigenous to many parts of Asia and Europe and naturalized in the United States, where it grows near dwellings, in waste places, and along roadsides.

Description.—The stem is quadrangular, gray-hairy, and branched; leaves opposite, petiolate, 1 to 3 inches (25 to 75 Mm.) long, triangular ovate, cordate or rounded at base, pointed at apex, the margin strongly crenate-serrate, grayish-green, soft hairy above and velvety beneath. The flowers are in terminal panicles, the lower stalked, the upper sessile, with a gray, hairy, obliquely five-toothed calyx and a whitish, purple-spotted corolla, which is hairy on the outside, has the three-lobed lower lip crenately toothed, and four stamens inserted in its tube. The stem and larger branches are rejected, the leaves and flowering tops only being collected in June and July. It has a peculiar mint-like rather disagreeable odor, and a bitterish, aromatic, and pungent taste. A variety, *N. citriodora*, *Becker*, has an agreeable lemon-like or melissa-like odor. On drying, the fresh drug loses from 75 to 80 per cent. in weight.

Constituents.—The chemical constituents resemble those of other *Labiatae*. The plant contains a small quantity of oxygenated volatile oil, some tannin, a bitter principle which has not been isolated, and other medicinally unimportant constituents.

Medical Action and Uses.—Catnep is stimulant and slightly tonic, and, like the mints and some other plants containing a volatile oil, it has been prescribed in various disorders attended with debility of the nervous system and of the functions immediately depending upon it. It is most commonly used for the relief of *flatulent colic* in infants and to promote *menstruation* when it is retarded or painful. Its local application excites a sense of warmth and causes partial anaesthesia, for which reason it is used to relieve *toothache* and other local pains. Cats are fond of it, hence the name *catnep* (cat-nepeta). It is given in an infusion made with from half an ounce to an ounce (Gm. 15–30) in a pint of water, and in the dose of from a teaspoonful to a tablespoonful.

CATECHU, *U. S.*, *P. G.*—CATECHU.

Terra Japonica, *Catechu nigrum*.—*Cutch*, E.; *Cachou*, Fr.; *Katechu*, *Pegu-Catechu*, G.

An extract prepared principally from the wood of *Acacia* (*Mimosa*, *Linneé jilius*) *Catechu*, *Willdenow*. Woodville, *Med. Bot.* 157; Bentley and Trimen, *Med. Plants*, 95.

Nat. Ord.—*Leguminosae*, *Mimoseae*.

Origin.—A tree about 30 to 40 feet (9 to 12 M.) high, with a pair of hooked brown prickles at the base of the numerous abruptly bipinnate leaves, which are 6 to 12 inches (15 to 30 Cm.) long, and with pale-yellow flowers arranged in dense cylindrical spikes about 3 inches (75 Mm.) long; the legume is brown, veined, flattened, and pointed.

The glabrous and pubescent varieties have formerly been regarded as distinct species, *Mimosa Sundra* and *M. catechuoides*, *Roxburgh*. The tree is indigenous to the East Indies and Ceylon, and is completely naturalized in Jamaica, where it is common in dry localities.

Preparation.—The wood, which is heavy and very durable, is covered by a dark-brown fibrous bark, and consists of the whitish alburnum and of the dark-colored heartwood, varying in color from red-brown to blackish-brown. This latter portion is cut into chips, which are boiled with water in earthen pots arranged over a rude fireplace, the decoction when sufficiently strong being decanted or strained into other vessels, in which the evaporation is continued until the extract is of sufficient consistence to be poured into clay moulds, into cups formed of leaves, or upon mats covered with the ashes of cow-dung.

In Southern India the wood of *Acacia* (*Mimosa*, *Roxburgh*) *Suma*, *Kurz*, whose bark is externally white, is employed in the same manner, the bark of both species being removed and used for tanning. The last-named species is also common in the forests of tropical Eastern Africa, and has been introduced into South America.

The importation of catechu and gambir into the United States increased from 2,645,000 pounds during the fiscal year 1866–67 to over 47,750,000 pounds in the year 1879–80; in 1882 but little over 15,000,000 pounds were imported.

Description.—Catechu is chiefly exported from Pegu and Calcutta, packed in mats, chests, or boxes. It forms several layers of dark-brown masses, in which remnants of the matting and of leaves are observed, and which are frequently soft near the centre. When

dry it is hard and brittle, breaking into irregular, somewhat porous and glossy fragments, which are scarcely translucent on the edges, almost wholly soluble in alcohol, partly soluble in water, and have but little odor and a strongly astringent and sweetish taste. The solutions have a slight acid reaction. Examined by the microscope under water or glycerin, catechu is somewhat crystalline. The catechu in balls and in quadrangular cakes, made in moulds as above described, is rarely met with in our commerce. A fourth variety, which is never exported, is made in Kumaon in Northern India by stopping the evaporation before the liquid becomes too thick; it bears a closer resemblance to gambir than to the ordinary catechu. Good catechu yields between 1.5 and 4.5 per cent. of ash; Flücker obtained from Pegu catechu 0.6 per cent.

The *Areca catechu*, obtained from the so-called betel-nuts, the seeds of *Areca Catechu*, Linné, does not form an article of commerce; it is said to be inferior to true catechu, and is known in India, in part at least, as *catta-cambu*. (See page 256).

Constituents.—The relation to one another of the principal constituents of catechu has been satisfactorily explained by the researches of Neubauer (1859), Hlasiwetz (1867), Etti (1877), and others. When catechu is treated with cold water mainly *catechu-tannic acid* is found in the brown solution, which yields precipitates of a grayish color with gelatin and of an olive-brown with ferric salts. The aqueous solution contains also some *catechin* and *quercetin*, the latter having been obtained by Löwe (1873) by treating the solution with ether. Most of the *catechin* or *catechuic acid* is, however, left undissolved by the treatment with cold water, and may be obtained pure by repeated crystallization and decolorizing with animal charcoal, or removing the adhering tannin by adding lead acetate until a dark-colored precipitate is no longer obtained. Catechin forms white silky needles which are sparingly soluble in cold water, but more readily in cold alcohol and ether; it requires for solution less than 4 parts of boiling water, about 3 parts of boiling alcohol, and 6 parts of boiling ether. It has a sweetish taste, imparts a green color to ferric salts, gives a violet color on being agitated with water and powdered iron, the color changing to green on exposure to air, and yields precipitates with most metallic salts, but not with tartar emetic nor with gelatin. Its formula, according to Rochleder (1869), is $C_{13}H_{12}O_5$. Subjected to dry distillation, it yields pyrocatechin, and when fused with potassa is converted into phloroglucin (see PHLOROZINUM) and protocatechuic acid. Gautier (1878) gives to catechin the formula $C_{21}H_{18}O_8$, and found among the products of decomposition by potassa, besides the two mentioned, also the hydrocarbon, CH_4 , and carbonic and formic acids. By the action of dilute sulphuric acid at 140° C. an amorphous orange-colored body, protocatechuic acid, and a polyatomic phenol, probably $C_{14}H_{16}O_7$, were obtained. Etti adopts Hlasiwetz's formula, $C_{19}H_{18}O_8$, for catechin; this is partly decomposed at 110° C. (230° F.), and when heated to 160° C. (320° F.) yields an anhydride, $C_{38}H_{34}O_{15}$, which is catechu-tannic acid, and has also been called *catechu-red*; it is a dark-red amorphous powder, soluble in water, alcohol, and ether. Below 180° C. (356° F.), or by continued boiling with dilute sulphuric acid, the anhydride, $C_{38}H_{32}O_{14}$, which is likewise a tannin, is obtained. By continuing the action of sulphuric acid the *catechuretine*, $C_{38}H_{28}O_{12}$, of previous investigators, and the anhydride, $C_{38}H_{30}O_{13}$, are obtained, which are insoluble in simple solvents and weak alkalis. H. K. Bowman (1869) determined the quantity of tannin in three samples of catechu, and found it to vary between 32.8 and 49.4 per cent. More than 30 samples examined by Lehmann (1880) yielded tannin varying between 22.6 and 50.8 per cent, and catechin varying between 13.8 and 33.8 per cent.

Protocatechuic acid, $C_7H_6O_5$, is formed from certain tannins, numerous resins, gum-resins, and other substances by adding them to melted potassa. It crystallizes in colorless shining needles or scales containing a molecule of water, dissolves readily in ether, alcohol, and hot water, melts at 199° C. (390.2° F.), and at a higher heat is decomposed into carbonic acid and pyrocatechin. Its solution is colored dark-green by ferric chloride, the color changing to blue, and subsequently to red, on the gradual addition of a very dilute solution of sodium carbonate.

Pyrocatechin or *catechol*, $C_6H_6O_2$, is contained among the products of destructive distillation of several tannins and vegetable extracts. It crystallizes in short rectangular prisms, melts at 104° C. (219.2° F.), and boils at 245° C. (473° F.). It sublimes in thin laminae, and dissolves easily in water, alcohol, and ether. Its aqueous solution is colored dark-green by ferric chloride, the color changing to violet on the addition of ammonia, sodium bicarbonate, or tartaric acid. The methylic ether of pyrocatechin is guaiacol. (See CREASOTUM.)

Impurities.—Fragments of leaves, mats, or cloth are usually found in the commercial

article. An *artificial catechu*, proposed by Rave (1873), may be obtained by slightly roasting powdered mahogany or allied woods, and then boiling with water; it is said to be serviceable in dyeing.

Off. Prep.—Tinctura catechu composita, Trochisci catechu, U. S.

Astringent Products of Other Species.—The bark of many species of acacia contains so much tannin as to render it valuable for tanning purposes. The *babul-bark* of India is obtained from *Ac. nilotica*, *Desfontaines*, the fruit of which is also used by tanners under the name of *neb-neb* or *bablah*. The Australian *wattle-bark* is produced by *A. decurrens*, *Willdenow*, and other species.

Cortex adstringens BRASILIENSIS, which was used in Europe during the first half of the present century, is obtained from *Stryphnodendron polyphyllum*, *Martius*, a tree known in Brazil as *barbatimao* or *barbimao*. The bark is covered with a thick fissured blackish red-brown cork, has a light-brown bast-layer readily separating in bands, possesses a strongly astringent and somewhat mucilaginous taste, and contains about 30 per cent of tannin, which yields with ferric salts a blackish gray-green precipitate. *Pithecollobium Avaremotemo*, *Martius*, s. *Acacia virginalis*, *Pohl*, and *Acacia Jurema*, *Martius*, yield similar barks.

CATECHU PALLIDUM, Br.—PALE CATECHU.

Catechu, P. G.; *Terra japonica*, *Gambir*, *Gambier*, E.; *Gambir cubique*, Fr.; *Gambir*, *Gambir-Catechu*, G.

An extract of the leaves and young shoots of *Uncaria Gambier*, *Roxburgh*, s. *Nauclea Gambier*, *Hunter*. *Trans. Linn. Soc.*, vol. ix. plate 22; Bentley and Trimen, *Med. Plants*, 139.

Nat. Ord.—Rubiaceæ, Naucleæ.

Origin.—This is a shrubby climber having opposite leaves, and bearing globular heads of pinkish flowers upon axillary laterally compressed peduncles, which taper toward the apex, are articulated above, and after the fall of the whole inflorescence curve backward and form stout and hard hooks, by which the plant supports itself in climbing. It is indigenous to Ceylon, Sumatra, and the countries about the Straits of Malacca, and is extensively cultivated near Singapore. *Uncaria* (*Nauclea*, *Hunter*) *acida*, *Roxburgh*, indigenous to Pulo Penang and neighboring islands, is nearly allied to the preceding species, and perhaps merely a variety of it; it appears also to be used in the preparation of gambir.

Preparation.—The fresh leaves and young shoots are boiled in water for an hour, after which the decoction is decanted and the residue expressed with the hands. The liquid is now evaporated to the consistence of a thin syrup, poured into buckets, and stirred by working a stick of soft wood up and down in a sloping direction, when it gradually sets into a soft mass; this is placed in shallow square boxes, and when sufficiently firm is cut into cubes and dried in the shade.

Gambir is principally exported from Singapore, packed in boxes. *Catechu*, P. G., applies to gambir as well as to catechu.

Description.—It is met with in cubes or in large irregular masses, the latter having an external resemblance to, but are mostly of a lighter-brown color than, catechu, and presenting upon the irregular fracture a dull brown-gray appearance, with some streaks of a darker brown. The cubes are about an inch (25 Mm.) square on each side, externally light or deep brown, internally brownish-gray. Both varieties are friable, inodorous, of a bitterish astringent finally sweet taste, and show under the microscope numerous small acicular crystals. Gambir is only partially soluble in cold water, but yields with hot water a turbid solution, and with hot alcohol a clear dark-brown solution, leaving only the impurities undissolved, and these should not exceed 15 per cent. in weight (*P. G.*). On incineration gambir yields $2\frac{1}{2}$ to $4\frac{1}{2}$ per cent. (not over 6 per cent., *P. G.*) of ash, consisting mostly of earthy salts.

Constituents.—Gambir contains the same constituents as catechu, but less tannin than the latter; the crystalline structure observed under the microscope is due to catechin. Hlasiwetz (1867) detected *quercetin* in gambir. De Vrij (1865) avers the presence of *quinoric acid* in many species of *Nauclea*, and it is not impossible that it may also be found in gambir. Gautier (1878) regards the catechin of gambir as differing in composition from that of catechu. Twelve samples of gambir examined by Lehmann (1880) yielded between 25.5 and 37.8 per cent. of tannin and between 19.96 and 28.69 per cent. of catechin.

Valuation.—Adolf Lehmann (1880) has proposed for both catechu and gambir the following method: Treat 1.5 Gm. with sufficient hot water to obtain 250 Ccm. and filter. Determine in a portion of the filtrate the tannin and catechin by Loewenthal's method (see ACID. TANNIC., p. 105), and in another portion the tannin alone by Schulze's method

(page 104). By subtracting the tannin from the mixed tannin and catechin the catechin (with coloring matter, etc.) is found.

Off. Prep.—Infus. catechu, Pulv. catechu comp., Tinct. catechu, Trochisci catechu, Br.

Medical Action and Uses.—Catechu is astringent by virtue of the tannic acid it contains, and was originally used to constrict relaxed tissues, arrest fluxes, and for similar purposes. It is harsher but more energetic than kino in its action. It continues to be one of the most commonly employed of astringent medicines for checking *diarrhæa* produced by cold or by irritating ingesta after their removal by purgation. It is best administered for this purpose in the officinal chalk mixture. It is alleged to check the bronchial secretion in chronic *phthisis* and *bronchitis*, and to moderate uterine *hæmorrhage* and *leucorrhæa*. It is of greater utility as a local astringent, applied to the nostrils in *epistaxis*, to the mouth in cases of spongy and bleeding *gums*, to the *vagina* in relaxation and leucorrhœa of this canal, and to the *throat* and *larynx* in cases of flaccidity of these parts. Lozenges containing it are used to correct *hoarseness* and roughness of the voice due to this cause. They sometimes are made with catechu, cascarilla, amber, orris, peppermint, etc. to conceal the odor of the breath caused by *fætid follicular secretions*, by *tobacco*, etc. The astringency of catechu renders it a useful ingredient of dentifrices. In gargles it relieves *sore throat* unattended with active inflammation; in lotions it forms a valuable application to ulcerated *nipples* and other *ulcers* after the acute stage has passed; such lotions may contain catechu alone, or, in addition to it, borax, alum, sulphate of copper, etc. Gambir catechu has the same medical properties, but its astringency is rather less. The *dose* of catechu is from 1 to 30 grains (Gm. 0.5–2.0). A compound infusion of catechu is made with 1 troyounce of this drug, 60 grains of powdered cinnamon, and a pint of boiling water. It is especially useful in the diarrhœa of children, to whom it may be given in doses of a tablespoonful or more.

CAULOPHYLLUM.—BLUE COHOSH.

Pappoose-root, Squaw-root, Blueberry-root.

The rhizome and rootlets of *Caulophyllum* (Leontice, *Linné*) thalioides, *Michaux.*

Nat. Ord.—Berberidaceæ.

Origin.—A smooth and glaucous perennial with a simple stem, bearing near its apex a large sessile trternately compound leaf, with obovate three- or five-toothed or lobed leaflets; the greenish-yellow flowers, about twelve in number, form a terminal raceme, and produce capsules which are soon ruptured by the two globular seeds, these remaining enclosed in a blue fleshy integument. The plant is found in rich woodlands from Canada south to Carolina and Kentucky. It flowers in April and May.

Description.—The rhizome is nearly horizontal, somewhat matted, 4 inches (10 Cm.) long, about $\frac{1}{4}$ to $\frac{2}{5}$ inch (6 to 10 Mm.) thick, more or less bent, knotty from the numerous concave approximate stem-scars on the upper side, and from the short branches, externally brown-gray, internally whitish, the tough ligneous rays narrow and many. The numerous radial fibres are mostly on the lower side, 3 or 4 inches (75 or 100 Mm.) long and about $\frac{1}{25}$ inch (1 Mm.) thick, rather tough, pale yellowish-brown externally, and white internally. Blue cohosh is nearly inodorous and has a sweetish-bitter afterward somewhat acrid taste. As met with in commerce, it is sometimes mixed with a large proportion of the rhizome of *hydrastis*, which is easily recognized by its different shape and its bright-yellow color internally.

Constituents.—F. F. Mayer (1863) found blue cohosh to contain *saponin*; Ebert (1864) corroborated this statement, proved also the presence of two resins, starch, gum, and other common principles, and obtained 2½ per cent. of ash. On concentrating the alcoholic tincture and pouring it into water a precipitate of the resins is obtained amounting to about 12 per cent. of the root; it has the peculiar taste of blue cohosh and constitutes the so-called *caulophyllin*.

Medical Action and Uses.—Nothing has recently been added to our knowledge of its reputed virtues. It is said to be demulcent, antispasmodic, emmenagogue, and diuretic. It is not proved to possess medicinal powers. A decoction made with an ounce (Gm. 30) of the root to a pint of water may be given in the dose of 1 or 2 ounces.

CEANOTHUS.—RED ROOT.

New Jersey tea, E.; *Céanothe*, Fr.; *Seckelblumen-Wurzel*, G.

The root of *Ceanothus americanus*, *Linné*.

Nat. Ord.—Rhamnaceæ.

Origin.—This is a shrubby plant indigenous to the greater part of North America, growing in pine barrens and dry woodlands. It is about 3 feet (90 Cm.) high, and has alternate ovate or oblong-ovate, serrate leaves, which are sometimes heart-shaped at the base, downy underneath, and three-veined. The small white flowers are in axillary panicles and produce three-lobed capsules containing three seeds.

Description.—The root is about a foot (30 Cm.) long, nearly cylindrical, an inch (25 Mm.) or more thick, with a knotty head and a few branches, and covered with a firmly-adhering rust-colored bark, which is about $\frac{1}{2}$ inch (2 Mm.) thick, with some longitudinal ridges, hard, breaks with a short granular fracture, and when cut with a knife has a brown-red and waxy appearance. The wood is very tough, of a light red-brown color and of a waxy lustre upon the recently-cut surface. The branches have a rather lighter-colored bark and a whitish wood. The root is without odor and has a bitterish-astringent taste, which is strongest in the bark.

Constituents.—Red root has not been analyzed, but is known to contain tannin. Bowman (1869) estimated the tannin of the leaves to amount to 9.21 per cent.

Other Species.—*Ceanothus ovalis*, *Bigelow*, which has narrow oval leaves, is indigenous from Vermont to the Rocky Mountains.

Cean. cœruleus, *Lagasca*, s. C. *azureus*, *Desfontaines*, a native of Mexico, has been employed there as a febrifuge.

Medical Uses.—The leaves of this plant were used during the American War of Independence as a substitute for Chinese tea, and in the late Civil War it was employed in the same manner, and pronounced "a good substitute for indifferent black tea." The root is astringent, and was applied locally by the Cherokee Indians in *gonorrhœa* and *cancer*, and given internally in *syphilis*. A decoction of the leaves and seeds has been used in *ulceration* of the mouth and throat, and internally in *dysentery*. In the West Indies and Mexico it is said that a species of *Ceanothus* (*C. reclinatus*, *De Candolle*) is used for the purposes mentioned (*Bull. de therap.*, xevii. 119).

CELASTRUS.—STAFFTREE-BARK.

False bittersweet, *Fevertwig*, *Staff-vine*, E.; *Celastre*, Fr.; *Celaster*, G.

The bark of *Celastrus scandens*, *Linné*.

Nat. Ord.—Celastraceæ.

Origin.—The staff tree is a native of Canada, and of the United States southward to North Carolina, growing in woods and thickets and twining about trees, ascending to a considerable height. The leaves are alternate, ovate-oblong, acuminate, and serrate; the flowers are in small axillary racemes, greenish-white, and produce orange-colored three-valved capsules containing from three to six seeds, which are covered with a scarlet-red arillus.

Description.—The root-bark, which is usually preferred, is in irregular thin quills or double quills, is nearly smooth, externally brown or dark orange-brown; the outer layer, which is rather tough, separates concentrically and shows another layer of a bright orange-red color, which covers the white, fragile, likewise concentrically-arranged liber. The internal surface is whitish and finely striate. The bark of the stem resembles the root-bark, but is externally of an ash-gray or brown-gray color. It is without odor and possesses a bitterish-sweet taste. The tough white wood is occasionally found adhering to the bark as met with in commerce.

Constituents.—The bark has not been analyzed, but Prof. Wayne (1872) obtained from it a principle in white minute crystals resembling chloral hydrate in appearance. The process for obtaining this *celastrin* has not been published.

Medical Uses.—"The bark has considerable reputation in domestic practice as an emetic, discutient, and anti-syphilitic; it also appears to possess some narcotic powers" (Griffith). It is popularly supposed capable of "removing hepatic obstructions," whatever that may mean.

CEPHALANTHUS.—BUTTONBUSH.

Buttonwood, *Crane willow*, *Swamp dogwood*, E.

The bark of *Cephalanthus occidentalis*, *Linné*.

Nat. Ord.—Rubiaceæ, Cinchonææ.

Origin.—The buttonbush grows in wet places in Canada and the United States, attains a height of 10 to 15 feet (3 to 4.5 M.), has ovate, acuminate, and entire leaves, which are opposite or in whorls of three, and the white flowers are aggregated in dense globular terminal and axillary heads.

Description.—Buttonbush-bark, as found in commerce, is in narrow curved pieces an inch (25 Mm.) or more in length. The outer surface is somewhat glossy, gray-brown, finely striate longitudinally, or when older covered with a scaly and fissured ash-colored or brown-gray soft cork. The inner bark is white and smooth, after drying light rust-brown, rather tough, and breaks with a fibrous fracture. The bark is inodorous and has a slightly astringent and somewhat bitter taste.

Constituents.—Examined by E. M. Hattan (1874), the bark was found to contain tannin, a principle analogous to saponin, an uncrystallizable bitter principle freely soluble in alcohol and water, two resins, fat, gum, glucose, and starch. A fluorescent body was obtained from the precipitates occasioned by acetate and subacetate of lead; it crystallizes in needles, is soluble in water, alcohol, and ether, yields a yellow precipitate with subacetate of lead, and has in alkaline solutions a yellow color, which in reflected light appears blue.

Medical Uses.—There is no evidence to prove that this plant possesses medicinal virtues sufficient to entitle it to consideration. It is reputed to have been useful in *paralysis, coughs, and constitutional syphilis*.

CERA ALBA, U. S., Br., P. G.—WHITE WAX.

Cire blanche, Fr.; *Weisses Wachs*, G.

Yellow wax bleached by exposure to moisture, air, and light.

CERA FLAVA, U. S., Br., P. G.—YELLOW WAX.

Cera citrina.—*Beeswax*, E.; *Cire jaune*, Fr.; *Gelbes Wachs*, G.

The prepared honeycomb of the hive-bee or honey-bee. *Apis mellifica*. *Linneé*.

Class Insecta. Order Hymenoptera.

Origin.—The insect has been domesticated from an early period, and several varieties are known; but the *Apis fasciata* of Egypt, *A. unicolor* of Madagascar, and *A. pallida* of South America may perhaps be all distinct species. The bees live in societies called *swarms*, which are composed of one female or *queen bee*, several hundred males or *drones*, and ten thousand or more *working bees*, which are females with undeveloped ovaries. The wax is secreted in thin scales between the rings of the belly, and is used in the construction of the hexagonal cells which form the comb and are filled with honey. To obtain the wax the honey is drained off, the comb expressed, melted in water, and after the impurities have subsided the wax is allowed to cool or run into suitable moulds. By filtering the crude wax through paper at a sufficiently elevated temperature a very handsome product is obtained. Beeswax is largely produced in the United States, particularly in some of the Western and Southern States, and its importation from the West Indies has decreased to 6000 or 7000 pounds annually.

Wax-Bleaching.—Melted beeswax is solidified in thin ribbon-like sheets by passing it over wet revolving cylinders, or it is finely granulated and then exposed to the light and air, being moistened from time to time and occasionally turned. It is then remelted, and the process repeated until the desired degree of whiteness has been attained. Wax may also be deprived of its color by chlorine, but such a product is much inferior to the sun-bleached wax.

Properties.—Beeswax is a solid body, having a more or less deep-yellow, or sometimes a brownish-yellow, color, a slight lustre, a somewhat unctuous touch, a finely granular fracture, a peculiar aromatic honey-like odor, and a slight balsamic taste. Its specific gravity varies between about .955 and .967, and its fusing-point between 62° and 63° C. (about 145° F.). The density of wax is, according to Hager, most conveniently determined by melting a small portion, dropping it upon a slightly dampened glass or porcelain tile, and immersing the solidified drops in alcohol of known density, in which they must float without rising to the surface or sinking to the bottom. Wax is brittle in the cold, becomes plastic by the heat of the hand, and when melted forms a clear reddish-yellow liquid, which congeals with a smooth and level surface and appears irregularly crystalline under the microscope. Wax is insoluble in water and slightly soluble in cold alcohol, but dissolves in 300 parts of boiling alcohol, leaving only a

small-brownish-yellow residue, and depositing on cooling a whitish crystalline mass, while the filtrate is yellowish, and not rendered turbid by water. Wax is wholly soluble in 11 parts of chloroform, in 10 parts of boiling ether, in warm benzol, benzin, carbon bisulphide, oil of turpentine, and other volatile oils, and in fixed oils. The U. S. Pharmacopœia states that wax is soluble in 35 parts of ether, while, according to Hager, ether dissolves only about one-half of the wax at 15° C. (59° F.), and benzol or benzin about 27 per cent. On dry distillation wax yields an aqueous liquid, a butyraceous oil, a scaly crystalline body, and empyreumatic products, but no acrolein.

White wax is usually met with in yellowish-white thin circular cakes, which are about 4 inches (10 Cm.) in diameter, slightly translucent, of a somewhat splintery fracture in the cold, have a specific gravity of about .965 to .975, and fuse near 64° C. (147° F.) (65° C.=149° F., *U. S. P.*). Its slight odor suggests that of rancidity; its taste is insipid. In other respects it has the characteristics and answers to the tests of yellow wax.

Constituents.—Yellow wax contains some aromatic and coloring matters, which vary somewhat in wax from different localities, and are destroyed by the bleaching process; they are partly dissolved by cold alcohol, together with a very small quantity of *cerolein*, which resembles a fat in appearance. Boiling 90 per cent. alcohol dissolves 10 to 20 per cent. of *cerin* or *cerotic acid*, $C_{27}H_{54}O_2$, which exists likewise in Chinese wax, is crystalline, and fuses in its pure state at about 81° C. (177.8° F.). Schalfelief (1876) succeeded, by fractional precipitation with lead acetate, in separating it into several acids, one having the composition $C_{34}H_{68}O_2$. Repeated boiling of wax with alcohol leaves yellow *myricin* behind, which is *myricyl-palmitate*, $C_{30}H_{61}.C_{16}H_{31}O_2$; when pure it forms feathery crystals, has the fusing-point at 72° C. (161.6° F.), is very sparingly soluble in alcohol, more freely in ether and oil of turpentine, and is with difficulty saponified by boiling with concentrated solution of potassa. The principle to which bleached wax owes its rancid odor has not been ascertained.

Vegetable wax is obtained in different countries from various species of *Myrica*, *Rhus*, *Corypha*, etc. Some of them are glyceryl compounds of fatty acids, and therefore true fats, but the exact composition of most of them has not been ascertained.

Adulterations and Substitutions.—The coarse adulterations with flour, white lead, and similar substances are perhaps rarely practised at the present time, since they are so readily detected by their insolubility in ether, chloroform, and oil of turpentine, and by subsiding or mixing with hot water on fusing the wax with it. The materials most frequently employed are resin, commercial stearin (the residue left on expressing lard oil), suet, and similar fats, and paraffin and the closely-allied *ceresin* or *ozokerite* of Galicia. The latter, which has also been termed *mineral*- or *earth-wax*, is found in nearly black masses, but is obtained in the process of purification of various shades of color varying between dark-yellow and white. This and *paraffin* may be readily detected and their quantity estimated by their stability when heated with concentrated sulphuric acid, by which the beeswax is completely destroyed, while they are not affected, and may be recovered nearly pure by fusing the residuary mass repeatedly with fresh portions of water. If the adulterated wax be previously exhausted with light petroleum benzin, which dissolves but little of the beeswax, the solution will contain the paraffin, together with any fat present, and the residue left on evaporation may be treated with sulphuric acid; this will destroy the fat and leave the paraffin. The determination of the specific gravity and fusing-point has been recommended for detecting adulterations, paraffin and tallow being lighter, while resins, stearin, Japan wax, etc. are heavier, than wax; but mixtures of the adulterants may be prepared which agree pretty well in these respects with the natural product. It must also be remembered that resins, like beeswax itself, are destroyed by the influence of hot sulphuric acid. But most resins and fatty acids are soluble without difficulty in cold strong alcohol, which takes up but minute quantities of beeswax; and this behavior affords a means of detecting such adulterations. Fats, however, are not dissolved by alcohol. With few exceptions they are readily soluble in cold petroleum benzin, and their quantity may be estimated. To apply these tests the wax should be cut into very thin pieces and digested for some time near the boiling-point. After cooling the liquid is decanted, and will then contain fatty acids and resin should alcohol have been used, or fats and paraffin if petroleum benzin should have been employed as the solvent. Advantage may also be taken of the behavior of Japan wax and other fats to form a milky emulsion on being boiled with an aqueous solution of borax, from which on cooling pure wax separates completely. When melted wax is allowed to congeal without being disturbed, it presents a level surface, but the surface of

paraffin is concave; and A. W. Miller (1874) has observed this distinctly even in mixtures of pure wax and paraffin; the translucent appearance of the latter is even noticed on the edges of the mixture, while pure yellow wax is almost opaque. Another perhaps still more deceptive fraud has been practised in coating adulterated with a thin layer of pure wax of the same color; and completely artificial wax has been made (1876) by fusing together rosin and paraffin or rosin, soap, and stearic acid: the solubility in cold strong alcohol, and in the former case the indestructibility of the undissolved portion by hot sulphuric acid, serve to detect these frauds. The admixture of fats may also be detected by the acrid odor of the vapors given off on throwing the suspected wax upon red-hot charcoal. (See paper on white wax and its adulterations by Prof. Bedford in *Proc. Amer. Pharm. Assoc.*, 1877, p. 444.)

Tests.—If 1 Gm. of wax be boiled for half an hour with 40 Gm. of solution of soda (sp. gr. 1.180), the volume being preserved by the occasional addition of water, the wax should separate on cooling, without rendering the liquid opaque, and no precipitate should be produced in the filtered liquid by hydrochloric acid (absence of fats or fatty acids, Japan wax, resin); nor should the same reagent produce a precipitate in water which has been boiled with a portion of the wax (absence of soap). If 5 Gm. of wax be heated in a flask for 15 minutes with 25 Gm. of sulphuric acid to 160° C. (320° F.), and the mixture diluted with water, no solid, wax-like body should separate (absence of paraffin).—*U. S.*

If the wax be boiled with alcohol sp. gr. .830, and the solution cooled and filtered, the filtrate should not, or only very slightly, redden blue litmus-paper, and should not become turbid on the addition of water (absence of resins and stearic acids). If 1 part of wax be boiled for 1 hour with 300 parts of alcohol sp. gr. .96 and 1 part of exsiccated sodium carbonate, and the liquid after cooling be filtered, the filtrate should not yield a precipitate on the addition of hydrochloric acid (absence of resins, fats, vegetable wax, and fatty acids).—*P. G.*

Off. Prep. of White Wax.—Ceratum, *U. S.*; Ceratum (Unguentum) cetacci, Charta cantharidis (epispastica), *U. S.*, *Br.*; Suppositoria, *Br.*; Unguent. aquæ rosæ, *U. S.*; Ungt. plumbi subacet. comp., Ungt. simplex, *Br.*

Of Yellow Wax.—Ceratum (Emplastrum) cantharidis, *U. S.*, *Br.*; Ceratum extracti cantharidis, *U. S.*; Ceratum (Unguentum) resinæ, *U. S.*, *Br.*; Emplast. asafœtidæ, Empl. picis burgund., Empl. picis canad., Empl. resinæ, *U. S.*; Empl. calefaciens, Empl. cerati saponis, Empl. galbani, Empl. picis, *Br.*; Unguentum, Ungt. mezerei, *U. S.*; Ungt. cantharidis, Ungt. hydrarg. comp., Ungt. hydrarg. oxidi rubri, Ungt. picis liquidæ, Ungt. sabinæ, Ungt. terebinthinæ, *Br.*

Medical Action and Uses.—Wax is simply a protective. Its use in ancient times as a remedy for *diarrhœa* and *dysentery* was doubtless due to this property. Quite recently it has been similarly employed. *Propolis*, a resinous matter with which bees cover the bottom of their hives, has been used for the same purpose. Until the introduction of caoutchouc, wax was generally employed for preparing impermeable tissues, and in the treatment of *rheumatism*, *gout*, *neuralgia*, and other local diseases to protect the affected parts from cold and favor cutaneous transpiration.

CERATA.—CERATES.

Cérats, Cértoles, Elæocértoles, Fr.; *Cerate, Wachssalben, G.*

The term cerate is applied to a class of unctuous preparations which in consistence are about intermediate between ointments and plasters, sufficiently soft to be spread at the ordinary temperature, and at the same time firm enough to adhere to the skin without melting. They are composed of wax, united with a fatty or oleoresinous substance, and to obtain them of proper consistence 2 parts of wax require about 3 parts of fixed oil, 4 parts of lard, or 1 part of soft turpentine. In preparing cerates the wax or resin should be melted first by the aid of a water-bath or otherwise carefully-regulated heat. When thoroughly melted, the warm oil or lard should be added in quantities small enough not to congeal the melted portion, and after all the ingredients have been liquefied and the vessel removed from the fire the mass should be well stirred or beaten with a spatula, to prevent the partial separation of the least fusible substances and ensure the perfect homogeneity of the preparation. It is well to continue this manipulation until the

temperature has been reduced to that of the room, but artificial refrigeration should not be applied until after the mass has thickened, and then only if vigorous stirring (or, better still, trituration) is kept up. With this in view, the soft cerate may be transferred to a mortar previously warmed by hot water, or the whole process may be completed in a well-enamelled iron vessel with a rounded bottom if a pestle fitting the curve of the latter be used. Straining is best avoided, and all the materials should therefore be free from dust and other foreign bodies. Powders, cantharides excepted, are gradually added while the cerate is merely soft enough to permit the whole to be uniformly mixed, and liquids should be previously warmed to 40° or 45° C. (about 110° F.). In dispensing cerates with extracts the latter should be previously rubbed with water in a warm mortar to a uniform thin paste, which should then be mixed with the cerate, added in small portions until the extract has been thoroughly incorporated; the remaining cerate may then be added in larger quantities.

Cerates should be kept in a cool place, where the temperature is not likely to rise much above 15° C. (59° F.), but even then those made with white wax, owing to its incipient rancidity, are liable to become rancid, while such as contain yellow wax keep unaltered for a much longer period. Some cerates, which are sufficiently firm, may be conveniently kept and dispensed in the form of square cakes, which are easily made by pouring the fused and nearly cool cerate into square moulds made of oiled or paraffin-paper and placed upon a flat slab. After the cerate has solidified it is without difficulty removed from the paper and cut into smaller pieces of any desired size or weight.

The name *steatina*, *steatins*, has been suggested by Mielck (1881) for a class of preparations which are of about the same consistence as cerates, but the base of which is suet, combined with either expressed oil of nutmeg, with wax, or with lead plaster deprived of glycerin and water.

CERATUM, U. S.—CERATE.

Ceratum simplex, U. S. 1850; *Ceratum adipis*, U. S. 1860; *Unguentum cereum*, P. G.—*Simple (lard) cerate*, E.; *Cérat simple*, Fr.; *Einfaches Cerat*, *Wachssalbe*, G.

Preparation.—White Wax 30 parts (6 oz.); Lard 70 parts (14 oz.); to make 100 parts (20 oz.). Melt them together, and stir the mixture constantly until cool.—U. S.

The simple cerate of the French Codex is composed of 1 part of white wax to 3 parts of expressed oil of almonds, and the wax ointment, P. G., of 3 parts of yellow wax to 7 parts of olive oil.

CERATUM CAMPHORÆ, U. S.—CAMPHOR CERATE.

Unguentum (Pomatum, F. Cod.) camphoratum.—*Pommade camphrée*, Fr.; *Kampfer-salbe*, G.

Preparation.—Camphor Liniment 3 parts (14½ grains); Olive Oil 12 parts (57½ grains); Cerate 85 parts (408 grains); to make 100 parts (480 grains). Mix the camphor liniment and the olive oil, and incorporate with the cerate.—U. S.

Melt at a moderate heat white wax 1 part and lard 9 parts; add powdered camphor 3 parts, and stir until the camphor is dissolved and until the ointment becomes cool.—F. Cod.

The consistence of the camphor cerate, U. S. P., is softer than that of most other cerates. The camphor pommade of the French Codex contains 12 per cent. of camphor, but the cerate of the U. S. P. only $\frac{3}{2}$ per cent.; it was made so weak solely for the purpose of preparing the *Ceratum plumbi subacetatis* extemporaneously.

Medical Action and Uses.—The only active ingredient of this preparation is camphor. It appears to be superfluous. If intended as an anti-pruriginous application, it is no better than camphorated oil. If proposed as an anodyne, it is vastly inferior to the ancient opodeldoc, which, it appears to us, should not have been laid aside in the revision of 1870 as well as in that of 1880.

CERATUM CANTHARIDIS, U. S.—CANTHARIDES CERATE.

Emplastrum cantharidis, Br.; *Emplastrum vesicans*, F. Cod.; *Emplastrum cantharidum ordinariū*, P. G.; *Emplastrum epispasticum s. vesicatorium*.—*Blistering cerate or plaster*, E.; *Emplâtre de cantharides*, *Emplâtre vésicatoire*, Fr.; *Spanischfliegen-Pflaster*, *Blasenpflaster*, G.

Preparation.—Cantharides, in No. 60 powder, 35 parts (7 oz.); Yellow Wax 20 parts (4 oz.); Resin 20 parts (4 oz.); Lard 25 parts (5 oz.); to make 100 parts (20 oz.). To the wax, resin, and lard, previously melted together and strained through muslin, add the cantharides, and by means of a water-bath keep the mixture in a liquid state for half an hour, stirring occasionally. Then remove it from the water-bath and stir constantly until cool.—*U. S.*

Take of Cantharides in powder 12 ounces; Yellow Wax, Prepared Suet, each 7½ ounces; Prepared Lard 6 ounces; Resin 3 ounces. Liquefy the wax, suet, and the lard together by a water-bath, and add the resin, previously melted; then introduce the cantharides, mix the whole thoroughly, and continue to stir the mixture while it is allowed to cool.—*Br.*

Cantharidin being freely soluble in fixed oils, the process of the *U. S. Pharmacopœia* always ensures an effectual blistering cerate, provided the cantharides are of good quality. It is important that the heat be not raised above 100° C. (212° F.), since cantharidin would volatilize with the watery vapors extricated from the powder, and, while weakening the cerate, vesication of the operator's face and hands would be apt to occur. The solution of the cantharidin in the cerate may be greatly facilitated by dampening the powdered cantharides with oil of turpentine or chloroform a day or two before the cerate is made. Dragendorff (1872) recommended a process for increasing the efficacy of the cerate by treating the powdered cantharides first with solution of potassa or soda, heating the mixture in a water-bath for half an hour, supersaturating with hydrochloric acid, drying rapidly in a water-bath, and powdering the residue. Rother (1872) obtained by this process an ineffectual preparation, unless the powder was finally kept moist for several days with chloroform or oil of turpentine, whereby, however, the activity of cantharides powder was likewise increased. H. G. Greenish (1880) again recommended the process.

The blistering cerate of the *U. S. P.* contains 35 per cent., that of the *Br. P.* and *F. Cod.* 33½ per cent., and that of the *P. G.* 25 per cent., of powdered cantharides.

Off. Prep.—Blistering cerate is an ingredient of *Emplast. picis cum cantharide, U. S.* The following two preparations are directed by the French Codex:

Camphorated cantharides plaster, E.; Vésicatoire camphrée, Fr.—It is made by diffusing upon the surface of the spread cerate a concentrated solution of camphor in ether or chloroform. As either solvent evaporates readily, a thin film of finely-divided camphor is left behind.

Vesicating cloth or taffetas, E.; Sparadrap (Toile, Taffetas) vésicant, Fr.—Melt together 100 parts each of purified elemi and resin, 375 of yellow wax, 225 of basilicon ointment, and 40 of olive oil; add 420 parts of finely-powdered cantharides and spread the mass over waxed cloth. Dubuison proposed a substitute for this, made by forming a thick solution of 1 part of gelatin in sufficient water, adding 4 parts of hydro-alcoholic extract of cantharides, and applying three layers of the mixture upon waxed cloth, allowing each one to dry before the next is applied.

Various proprietary articles of a similar nature are in the market; but the above, in addition to blistering-paper (see *CHARTA CANTHARIDIS*), will probably meet all necessities.

Medical Action and Uses.—Cantharides cerate forms the most usual blistering plaster. Its mode of action and remedial application are sufficiently explained under *CANTHARIS*.

CERATUM CETACEI, *U. S.*—SPERMACETI CERATE.

Emplastrum spermatis ceti, Ceratum labiale album.—*Cérat de blanc de baleine, Onguent blanc, Fr.; Walrat-Cerat, G.*

Preparation.—Spermaceiti 10 parts (1 oz.); White Wax 35 parts (3½ oz.); Olive Oil 55 parts (5½ oz.); to make 100 parts (10 oz.). Melt together the spermaceiti and wax; then add the olive oil, previously heated, and stir the mixture constantly until cool.—*U. S.*

It should be white and free from rancidity. The preparation of the *P. G.* 1872 was similar, but firmer, so as to form a convenient application to chapped hands and lips. For the latter purpose it is usually colored red by carmine or by previously steeping some alkanet-root in the oil and scenting it with some volatile oil.

The following preparations are used for similar purposes:

CERATUM ROSATUM, F. Cod.—Rose cerate, Lip salve, *E.*; *Cérat à la rose, Pommade pour les lèvres, Fr.; Lippenpomade, G.*—Melt together at a moderate heat white wax 50 Gm. and expressed oil of almond 100 Gm.; when partly cooled add carmine 0.5 Gm. pre-

viously rubbed up with a little of the oil; stir well, and finally add essential oil of rose 0.5 Gm.—*F. Cod.*

CAMPHOR ICE.—Melt together 4 ounces of white wax and 12 ounces of benzoated suet; when nearly cool add 2 ounces of powdered camphor and 2 drachms of oil of lavender. Mix and pour into suitable moulds (W. C. Bakes, 1867).

MEDICATED CACAO-BUTTER.—Melt together 4 ounces of yellow wax and 28 ounces of cacao-butter; add 1 drachm each of balsam of Peru and benzoic acid. Mix and pour into moulds (Ferris Bringham, 1867).

Medical Action and Uses.—Spermaceti cerate forms a very bland dressing for blisters, superficial abrasions, and ulcers after their primary stage. It is less apt than simple ointment to grow rancid.

CERATUM EXTRACTI CANTHARIDIS, U. S.—CERATE OF EXTRACT OF CANTHARIDES.

Cérat d'extrait de cantharides, Fr.; Cantharidenextract-Cerat, G.

Preparation.—Cantharides, in No. 60 powder, 30 parts (6 oz. av.); Resin 15 parts (3 oz. av.); Yellow Wax 35 parts (7 oz. av.); Lard 35 parts (7 oz. av.); Alcohol a sufficient quantity. Moisten the cantharides with 18 parts ($3\frac{3}{4}$ oz. av. or $4\frac{1}{4}$ fluidounces) of alcohol, and pack firmly in a cylindrical percolator; then gradually pour on alcohol until 180 parts (36 oz. av., or nearly $2\frac{1}{2}$ pints) of percolate are obtained, or until the cantharides are exhausted. Distil off the alcohol by means of a water-bath, transfer the residue to a tared capsule, and evaporate it on a water-bath until it weighs 15 parts (3 oz. av.). Add to this the resin, wax, and lard, previously melted together, and keep the whole at a temperature of 100° C. (212° F.) for 15 minutes. Lastly, strain the mixture through muslin and stir it constantly until cool.—*U. S.*

This was proposed by W. R. Warner (1860). The cantharidin is completely extracted by the alcohol, and again dissolved from the resulting soft extract by the lard, the solution in the latter being facilitated by the prolonged digestion. A quantity of blackish extractive matter, insoluble in fats, separates, and is removed by straining. The finished cerate is of a yellow or greenish-yellow color.

Medical Action and Uses.—They are the same as those of cantharides cerate, for which it is intended to be an elegant and efficient substitute.

CERATUM PLUMBI SUBACETATIS, U. S.—CERATE OF SUBACETATE OF LEAD.

Unguentum plumbi subacetatis compositum, Br.; Unguentum plumbi, P. G.; Ceratum cum subacetate plumbico, F. Cod.—Goulard's cerate, Compound ointment of subacetate of lead, E.; Cérat de saturne, C. saturné, C. de Goulard, Fr.; Bleisalbe, Bleicerat, G.

Preparation.—Solution of Subacetate of Lead 20 parts (90 grains); Camphor Cerate 80 parts (360 grains); to make 100 parts (450 grains). Mix them thoroughly. This cerate should be freshly prepared when wanted for use.—*U. S.*

Take of Solution of Subacetate of Lead 6 fluidounces; Camphor 60 grains; White Wax 8 ounces; Oil of Almonds 1 pint (Imperial). Melt the wax with 16 ounces of the oil by the heat of a water-bath, remove the vessel, and as soon as the mixture begins to thicken gradually add the solution of subacetate of lead, and stir the mixture constantly while it cools; then add the camphor dissolved in the rest of the oil, and mix thoroughly.—*Br.*

The present formula of the U. S. P. is a simplification of the alternative one of 1870, and will yield an unobjectionable preparation as long as the camphor cerate from which it is made has not become rancid. It is far preferable to the similar preparations of the other pharmacopœias, that of Germany being made of 8 parts of solution of subacetate of lead and 92 parts of lard; while that of the French Codex contains more water than that of the British Pharmacopœia, and becomes rancid even more readily than the latter. By replacing the white wax with yellow wax the cerate will keep for a much longer time, but its yellowish color will change to white on exposure to the atmosphere.

Medical Action and Uses.—This cerate is astringent and protective, and is employed to promote the healing of suppurating surfaces, such as excoriations, blisters, ulcers, etc. It is objectionable from its tendency to become rancid, and therefore irritating; and it must be cautiously applied upon extensive raw surfaces, lest it cause lead-poisoning.

CERATUM RESINÆ, U. S.—RESIN CERATE.

Unguentum resinæ, Br.; *Unguentum basilicum*, P. G.; *Unguentum tetrapharmacum*.—*Ointment of resin*, *Basilicon ointment*, E.; *Cérat de résine anglais*, *Onguent basilicum*, Fr.; *Harzsalbe*, *Königssalbe*, *Zugsalbe*, G.

Preparation.—Resin 35 parts (7 oz.); Yellow Wax 15 parts (3 oz.); Lard 50 parts (10 oz.); to make 100 parts (20 oz.). Melt them together at a moderate heat, strain the mixture through muslin, and allow it to cool without stirring.—*U. S.*

Take of Resin in coarse powder 8 ounces; Yellow Wax 4 ounces; Simple Ointment 16 ounces. Melt with a gentle heat, strain the mixture while hot through flannel, and stir constantly while it cools.—*Br.*

The impurities always present in the resin necessitate the straining of this and the following cerate. By melting and straining the resin alone the purified resin may be kept on hand and subsequent straining avoided. The formulæ of the French and German Pharmacopœias differ considerably from the foregoing, the former ordering black pitch, the latter turpentine, among the ingredients.

Off. Prep.—*Linimentum terebinthinæ*, *U. S.*

Allied Preparation.—CERATUM RESINÆ COMPOSITUM, *U. S.* 1870.—Compound resin cerate, Deshler's salve, *E.*—Take of resin, suet, yellow wax, each 12 troyounces; turpentine 6 troyounces. Melt them together, strain the mixture through muslin, and stir it constantly until cool.

This cerate, which was recognized by the U. S. P. until 1880, gradually becomes tough in consequence of the oxidation of the flaxseed oil—an alteration prevented by substituting for the flaxseed oil either a non-drying oil or paraffin oil, as suggested by S. A. D. Sheppard (1878).

Medical Action and Uses.—Resin cerate is one of the most common and useful of the dressings employed for slowly-healing and indolent sores, particularly when they have followed a local shock, such as is produced by a burn or scald.

Compound resin cerate is rendered more stimulant than resin cerate by the turpentine it contains, and may be applied where that preparation appears to act too feebly.

CERATUM SABINÆ, U. S.—SAVINE CERATE.

Unguentum sabinæ, Br., P. G.—*Ointment of savin*, E.; *Cérat de sabine*, Fr.; *Sadebaumsalbe*, G.

Preparation.—Fluid Extract of Savin 25 parts (5 oz.); Resin Cerate 90 parts (18 oz.). Melt the resin cerate by means of a water-bath, add the fluid extract of savin, and continue the heat until the alcohol has evaporated; then remove the heat and stir constantly until cool.—*U. S.*

Take of Fresh Savin Tops, bruised, 8 ounces; Yellow Wax 3 ounces; Prepared Lard 16 ounces. Melt the lard and the wax together on a water-bath, add the savin, and digest for 20 minutes. Then remove the mixture and express through calico.—*Br.*

Of the two preparations, we prefer the first, which was first suggested by Prof. Grahame (1858), and which contains all the soluble principles of savin. It is difficult to imagine that the brief digestion of the fresh savin ordered by the second formula should extract enough of the principles to render the cerate equally efficient. Both are, however, in point of elegance, improvements over the old method of incorporating the powder. The German Pharmacopœia employs an extract made with diluted alcohol, which is incorporated with nine times its weight of simple cerate.

Medical Action and Uses.—It is used exclusively as a stimulant of suppurating surfaces, whose discharges it tends to increase. Hence it is applied to prolong the secretion of *issues*, *setons*, and *blisters*, and has the advantage over preparations of cantharides that it does not tend to occasion stranguary. Its application produces a white pellicle of coagulable lymph, which should be from time to time removed, lest the part heal prematurely.

CEREVISIÆ FERMENTUM, Br.—BEER YEAST.

Fermentum, *U. S.* 1870.—*Yeast*, *Brewer's yeast*, E.; *Levâre de bière*, Fr.; *Bierhefe*, G.

The ferment obtained in brewing beer.

Origin and Description.—It has been previously stated (see ALCOHOL, p. 140) that alcoholic fermentation depends upon the development of a minute fungoid vegetable, *Saccharomyces cerevisiæ*, *Schwann et Meyen*, which has also been named *Torula* (*Cryptococcus*, *Kützing*, s. *Hormiscium*, *Bail*) *cerevisiæ*, *Turpin*. *Leuwenhoek* (1680) noticed already, under the microscope, the spherical granules in yeast, but their nature as vegetable organisms was not recognized until after 1820. *Persoon*, *Desmazières*, *Kützing*, and others determined their unicellular condition; *Latour* observed their budding; and *Schwann* studied their development. Besides the one named above, *Reess* (1870) has distinguished a number of other forms which are met with in fermenting liquids only under certain conditions. The possible vegetation of these organisms in the absence of free oxygen seems to have been proven, but the exact conditions have not been determined.

FIG. 59.

Yeast-cells.

There are two varieties of brewer's yeast—the *upper* or *top yeast*, and the *lower* or *bottom yeast* (*Oberhefe* and *Unterhefe* of the Germans). The former is the kind most generally met with in the United States, and is a viscid, semi-fluid, frothy mass containing large more or less globular microscopic cells from which smaller ones are developed; it appears upon the surface of the fermenting liquid, and is reproduced therein at a temperature ranging between about 15° and 20° C. (59° and 68° F.). But wort fermented with top yeast at a temperature near or below 10° C. (50° F.) will produce both top and bottom yeast, the latter being solely reproduced by the fermentation from below (*Unter-gährung*, *G.*) at a temperature of about 9° C. (48° F.) and less. It consists of various-sized cells differing from those of the top yeast in not having any small cells attached, and appears to be reproduced from isolated spores, while the other variety multiplies by budding. The cell-membrane consists of a kind of cellulose, and the contents of a protein compound analogous to albumen.

At a temperature less than 5° C. (41° F.) the yeast-plant ceases to vegetate, but it may be exposed to a cold of -60° C. (-76° F.) without being killed. At an elevated temperature of 75° C. (167° F.), and above, it loses its vitality unless water be absent, when it will not be destroyed by a temperature of 100° C. (212° F.) or more. On removing most of the water by pressure the *dry yeast* of commerce is obtained, which may be kept in this condition without material alteration. *Vienna yeast* is the same article, and is stated by *Dr. Vigla* (1871) to be made by fermenting a wort obtained from a mixture of maize and rye with barley malt, skimming off the froth, draining, and subjecting it to pressure. So-called *artificial* or *patent yeast* is either made of flour dough with the addition of a little yeast, or of an infusion of hops to which malt is subsequently added. The existence in hops of a ferment, as asserted by *Sacc* (1875), was denied by *Soxhlet* and *Pasteur* (1876), who proved that the only effect of hops, when used as stated above, is to impart some bitterness to the mass and somewhat delay the spoiling of the product.

When yeast is added to a solution of pure sugar, active fermentation takes place, the yeast being gradually rendered inert, but in the presence of albuminous matters in the saccharine liquid the yeast-plant is continually reproduced and augmented.

Some investigators have assumed the presence in yeast of a peculiar fermenting principle, *invertin*, which is prepared by *Barth* (1878) by expressing the water from yeast, drying it completely, heating for 6 hours to between 100° and 105° C. (212° and 221° F.), macerating with water at 40° C. (122° F.), and pouring the filtrate into six times its bulk of alcohol. The precipitate consists of the ferment and albumen, of which the latter is rendered insoluble by prolonged treatment with strong alcohol. *Invertin* is then dissolved by water, the solution precipitated by alcohol, and the precipitate dried, when it constitutes a brown horn-like mass, which is reduced to powder with difficulty.

Medical Uses.—As a topical remedy yeast has been spoken of under CATAPLASMA FERMENTI. Yeast is generally described as nutritive and antiseptic when used internally. The former it can be only in a slight degree, from the fermented malt liquor which may be mixed with it. It is antiseptic through the carbonic acid which it evolves. There is no doubt that it has appeared to be serviceable in the *typhoid states* of febrile diseases, and that it really is so when applied as a dressing to *gangrenous* and *phagedenic sores*, whose fetor it corrects while it stimulates the nutritive processes in the affected tissues. That its action is a stimulant one is shown by the pain it sometimes causes and by its

popular use in the treatment of recent *bruises*. Through its carbonic acid it must also be anodyne. The power of yeast to convert starch directly into alcohol has been invoked in the treatment of *diabetes*, and in a few cases has caused the total disappearance of sugar from the urine. Some patients show signs of alcoholic intoxication while undergoing this treatment. The yeast may be given in doses of 2 tablespoonfuls (Gm. 32) immediately before meals. It has also been used in *scurvy*.

CERII OXALAS, U. S., Br.—OXALATE OF CERIUM.

Cerium oxalicum, Oxalas cericus.—*Oxalate de cerium*, Fr.; *Oxalsäures Ceroxydul, Ceroxalat*, G.

Formula $\text{Ce}_2(\text{C}_2\text{O}_4)_3 \cdot 9\text{H}_2\text{O}$. Molecular weight 708.

Origin.—The metal cerium was discovered in 1803 in a Swedish mineral simultaneously by Klaproth and by Berzelius and Hisinger. The last-named chemists called the mineral *cerite*, after the planet Ceres, then recently discovered, and the metal *cerium*. Mosander (1839 and 1840) observed in the supposed pure oxide of cerium the oxides of two other hitherto unknown metals, which received the names of *lanthanum* and *didymium*. The three metals exist together as silicates in the cerite and allanite, the latter mineral being found in Scandinavia and in the States of New York and Pennsylvania. Mendelejeff (1870) first showed the atomicity of cerium in ceric compounds to be quadrivalent $= \text{Ce}^{\text{IV}}$, and in cerous compounds sexivalent $= \text{Ce}_2^{\text{VI}}$; its atomic weight was afterward determined to be 141.2.

Preparation.—To obtain oxalate of cerium F. F. Mayer (1860) recommended the following process: The powdered mineral is heated with concentrated sulphuric acid to decompose the silicates, the dry mass ignited, then dissolved in dilute nitric acid, and treated with sulphuretted hydrogen to remove copper, etc. A little hydrochloric acid is added to prevent the precipitation of calcium salt, and the cerite metals are precipitated as oxalates by oxalic acid. The precipitate is mixed with carbonate of magnesium, the mixture calcined to decompose the oxalates, the residue dissolved in a small portion of concentrated nitric acid, and the solution thrown into a large quantity of water containing about $\frac{1}{2}$ per cent. of sulphuric acid. Lanthanum and didymium remain in solution, together with the magnesium and a little cerium, most of which is precipitated as yellow ceric sulphate; the latter is dissolved in sulphuric acid and reduced to cerous sulphate by sodium hyposulphite, when the oxalate may be precipitated by oxalic acid.

Properties and Tests.—Oxalate of cerium is a white granular, inodorous, and tasteless powder, permanent in the air, insoluble in the simple solvents, but soluble in sulphuric and hydrochloric acids without effervescence (absence of carbonates); and this solution is not precipitated or colored by sulphuretted hydrogen (absence of heavy metals). When calcined in contact with the air the salt yields yellow ceric oxide, which has a brown tint if didymous oxide is present; 1 Gm. of the salt, thus treated, yields a residue weighing 0.466 Gm. Cerium oxalate dissolves in boiling potassa solution, and the clear liquid is not precipitated when mixed with sulphide of ammonium (absence of zinc), or when heated with excess of ammonium chloride (absence of aluminium compounds). When the potassa solution is acidulated with acetic acid it remains clear, but yields with calcium chloride a white precipitate of calcium oxalate, which is soluble in hydrochloric acid.

Other Salts of Cerium.—CERII CARBONAS, $\text{Ce}_2(\text{CO}_3)_3 \cdot 9\text{H}_2\text{O}$ (mol. weight 624), is prepared by precipitating cerous sulphate (see above) with carbonate of ammonium. The white flocculent precipitate changes to scales of a silvery lustre, which are insoluble in water and contain 52.4 per cent. of cerous oxide and 26.2 per cent. of water of crystallization.

CERII BROMIDUM. On dissolving cerous carbonate in hydrobromic acid and evaporating the solution, Bullock (1871) obtained a chocolate-colored, sweet, styptic mass which is freely soluble in alcohol, but leaves an insoluble residue of cerous compound on treatment with water. Chloride and iodide of cerium are likewise readily decomposed, the former becoming yellow, the latter brown, on exposure to the air.

CERII NITRAS, $\text{Ce}_2(\text{NO}_3)_6 \cdot 12\text{H}_2\text{O}$ (mol. weight 870). It is conveniently made by the mutual decomposition of cerous sulphate and barium nitrate, and filtering the cerous nitrate from the insoluble barium sulphate. The salt is very deliquescent, crystallizes in colorless prisms or scales, contains 37.9 per cent. of cerous oxide, and is freely soluble in water and alcohol.

Medical Action and Uses.—Oxalate of cerium was presumed to be a sedative of disordered nervous action, because it seemed to be an efficient remedy for the *vomiting of pregnancy*, and less frequently for vomiting due to irritable conditions of the stomach

itself. This statement has been amply confirmed by general experience since it was first made. In proportion as vomiting is of reflex origin it is under the control of this medicine, which is far less efficient, or fails altogether, when the symptom is the result of material gastric disease, such as simple or cancerous ulcer, or the wasting of the mucous membrane which sometimes attends habitual vomiting in advanced phthisis. Many cases designated as "dyspepsia" present material lesions of the stomach, and in these oxalate of cerium is as useless as bismuth is useful; the one generally fails, the other usually succeeds, in relieving the irritability of the organ. Some have even attributed to it curative virtues in epilepsy and chorea, but experience has not confirmed these statements. In 1880 (*Med. Record*, xvii. 492, 664) attention was drawn to this preparation as an efficient palliative of the cough of phthisis. It was represented, however, to be by no means uniform in its effects, and as soon losing its primary control over the symptom. It was thought to have over other cough medicines the advantage of not deranging the digestion. It was administered in 10-grain, and even in 20-grain, doses, without injury, and some preparations of it were found quite inert. It may be prescribed in doses of from 1 to 4 grains (Gm. 0.05–0.20) three times a day, but if these doses prove inoperative they may be increased even to twice or thrice as much. It may be given in pill or in powder, the latter being preferable. Simpson, who first used the preparations of cerium in medicine, regarded the oxalate as "almost a specific in chorea," and the nitrate as a nervine tonic "useful in chronic intestinal eruption, irritable dyspepsia with gastrodynia and pyrosis, and chronic vomiting generally, as well as in that of pregnancy. The dose is the same as that of the oxalate" (*U. S. Dispensatory*, 1870).

CETACEUM, U. S., Br., P. G.—SPERMACETI.

Spermaceti.—*Spermaceti*, Fr., G.; *Blanc de baleine*, *Cétine*, *Ambre blanc*, Fr.; *Walrat*, G.

Nearly pure cetin, obtained from the head of the sperm whale, *Physeter macrocephalus*, Linné.

Class Mammalia. Order Cetacea. Family Physeteridæ.

Origin.—The sperm whale, or great-headed cachalot, is principally met with in the Pacific and Indian Oceans and the seas of Australia. It is 50 to 70 feet (15 to 21 M.) long, with a head fully one-third of its entire length and correspondingly thick. Anterior to the cranium the upper jaw has a large cavity containing an oily liquid, which is removed with buckets soon after the animal has been killed, and then congeals into a yellow mass. This is drained in suitable bags, and then strongly expressed to remove the oil; the pressed cake is purified by melting it in water, skimming off the impurities, boiling with weak potassa solution, and washing with water; it is finally allowed to congeal.

Description.—*Spermaceti* is in white, translucent, scaly-crystalline masses somewhat unctuous to the touch, of a slight fatty odor, a mild bland taste, a laminated pearly fracture, and of a neutral reaction. Its specific gravity is 0.943 (0.945, *U. S.*) at 15° C. (59° F.). melts near 50° C. (122° F.) (between 50 and 54° C., *P. G.*), to a clear and nearly colorless liquid, and congeals at about 45° C. (113° F.). It contains variable but small quantities of oil, which cause *spermaceti* to become yellowish on exposure to air and to acquire a rancid odor and acid reaction. It is slightly soluble in cold benzin and benzol, but dissolves in chloroform, ether, carbon bisulphide, warm methyl and ethyl alcohol, and in fixed and volatile oils. On dry distillation an oily liquid, a solid fatty compound, and various gases and volatile acids are obtained. *Spermaceti* is readily inflammable, and burns with a bright somewhat sooty flame.

Spermaceti oil is yellow, has an unpleasant odor, a density of .910, remains liquid at −18° C. (−0.4° F.), and is difficult to saponify.

Constituents.—When repeatedly recrystallized from boiling alcohol the fat is removed and Chevreul's *cetin* is obtained, which crystallizes in soft white pearly scales, melts between 50.5° and 53.5° C. (123° and 128.3° F.), and is slowly decomposed by aqueous solution of potassa, but readily saponified on fusion with potassium hydrate or on boiling with its alcoholic solution. It consists mainly of cetyl palmitate, $C_{16}H_{33}.C_{16}H_{31}.O_{22}$, which melts between 54.5° and 55° C. (130° and 131° F.), and yields on saponification palmitic acid and cetyl alcohol, or *ethal*, $C_{16}H_{34}O$. Heintz (1854) obtained also small quantities of myristic, lauric, and stearic acids, and of the alcohols methal, $C_{14}H_{30}O$, and stethal, $C_{18}H_{38}O$. When boiled with nitric acid *spermaceti* is slowly oxidized, enanthylic, succinic, and other acids being found among the products.

Impurities and Adulterations.—Rancid *spermaceti* may be restored by boiling

it with a weak solution of potassa, and afterward with water. The admixture of fats deprives it of its pearly lustre. "1 part of spermaceti should be completely dissolved by 40 parts of boiling alcohol spec. grav. .832 (absence of fats); after cooling the solution and filtering from the crystalline mass the filtrate should not have an acid reaction, and should yield at most a slight precipitate on the addition of water (absence of fatty acids). On repeating the boiling after the addition of 1 part of exsiccated sodium carbonate, the cold filtrate, on being acidulated, should merely become turbid."—*P. G.*

Pharmaceutical Preparations.—When needed in the form of powder, spermaceti is triturated in a mortar, a little alcohol being added from time to time; or, better still, it is fused, and then well triturated until cold.

CETACEUM SACCHARATUM *s. PRÆPARATUM*.—Prepared or saccharated spermaceti, *E.*; Blanc de baleine saccharé, *Fr.*; Walratzucker, *G.*—Spermaceti 1 part and white sugar 3 parts are rubbed together to a very fine powder.

Spermaceti is contained in Ceratum cetacei, *U. S.*; Charta cantharidis (epispastica), *U. S.*, *Br.*; Ung. aquæ rosæ, *U. S.*; Ung. cetacei, *Br.*

Medical Action and Uses.—Spermaceti, like other fatty substances, is a lenitive. In the form of a fine powder and mixed with sugar (1 part to 3), it is a popular and useful remedy for commencing sore throat and catarrhal inflammation of the air-passages. Alvine and urinary irritations are also reputed to be benefited by its use. For these affections it is best administered in emulsion with the yolk of egg or with almond oil.

CETRARIA, *U. S.*, *Br.*—CETRARIA.

Lichen Islandicus, *P. G.*—Iceland moss, *E.*; *Lichen (Mousse) d'Islande*, *Fr.*; *Isländisches Moos*, *Isländische Flechte*, *Lungenmoos*, *G.*

The entire lichen, *Cetraria islandica*, *Acharius*, *s. Lichen islandicus*, *Limé*. Woodville, *Med. Bot.*, plate 205; Bentley and Trimen, *Med. Plants*, 302.

Nat. Ord.—Lichenes.

Origin.—The plant is indigenous to the northern hemisphere; in its southern limits it is found in mountainous regions, and farther north in the plains. In North America it

is met with from New England southward to the mountains of North Carolina, northward throughout British America, and westward to the Rocky Mountains as far south as Colorado; in Europe it grows as far south as Spain and Italy, and in Asia throughout Siberia and in the Himalaya Mountains; it is plentiful in Iceland, from which island its name is derived.

FIG. 60.

Cetraria islandica.

Description.—It is from 2 to 4 inches (5 to 10 Cm.) high, foliaceous, irregularly branched, with smooth somewhat channelled, nearly linear, obtuse, toothed, and ciliate lobes; the upper surface is greenish-gray or olive-brown, lower surface whitish, with depressed spots; the apothecia or so-called fruits, when present, are situate near the margin, round or oval, chestnut-brown, and flattish with an elevated margin. When dry it is brittle and inodorous, but immersed in water it becomes soft, leathery, and cartilaginous, and has a slight odor; its taste is mucilaginous and bitter. Boiled with 20 parts of water, it yields

a liquid which on cooling forms a bitter jelly; and on diluting this with an equal weight of water and adding alcohol, a flocculent precipitate is obtained which while moist is colored blue by iodine.

Impurities, such as pine-leaves, mosses, and other lichens, are usually found in the commercial article, and the drug frequently requires garbling. Adulterations are not likely to be intentional, but the lichen, as collected from different localities, is apt to vary somewhat in size and color and in the shape and width of the divisions.

Constituents.—Iceland moss was last analyzed by Knop and Schnedermann (1845). The principal constituent is *lichenin* or *lichen starch*, $C_{12}H_{20}O_{10}$, which is present to the amount of 70 per cent. It separates from its solution in hot water as a jelly, is insoluble in alcohol, but dissolves freely in solution of ammoniated copper, and by long-continued boiling with water is converted into a body resembling dextrin, and into glucose if boiled with dilute acids. In the moist state it is colored blue by iodine; the compound to which this behavior is due, according to T. Berg (1873), may be removed by continued washing with cold water. The bitter taste is due to about 2 per cent. of *cetraric acid* or *cetrarin*,

$C_{18}H_{16}O_8$, which is contained, in an uncombined state, mainly in the outer layer of the tissue. It forms colorless fine needles, which are nearly insoluble in water, soluble in boiling alcohol and alkalies, and yield with ammonia a yellow very bitter solution, which on exposure turns brown. The other constituents of Iceland moss are *lichen-stearic acid*, $C_{11}H_{21}O_3$ (about 1 per cent., soluble in alcohol, ether, volatile oils, and fats, fusible at 120° C.), *thallochlor* (a variety of chlorophyll, not soluble in hydrochloric acid), *fumaric* (formerly called *lichenic*) and *oxalic acid*, sugar, etc., and 16.7 per cent. of cellulose. The production of alcohol from Iceland moss, as proposed by Sten. Stenberg (1870), depends upon the formation of glucose from lichenin, noticed above. Iceland moss yields about 2 per cent. of ash.

Pharmaceutical Preparations.—Iceland moss is used in making Decoctum cetrariæ, *U. S.*, *Br.* The following preparations are used in Europe:

LICHEN ISLANDICUS AB AMARITIE LIBERATUS, Iceland moss free from bitterness. 15 parts of cut Iceland moss are macerated for 3 hours in 90 parts of tepid water containing 1 part of potassium carbonate in solution, and afterward well washed in cold water.—*P. G.* 1872.

GELATINA LICHENIS ISLANDICI, Iceland moss jelly. 3 parts of washed Iceland moss are boiled for half an hour with 100 parts of water, and expressed; the decoction is strained, and, after adding 3 parts of white sugar, evaporated to 10 parts.—*P. G.*

GELATINA LICHENIS ISLANDICI SACCHARATA SICCA.—Saccharure (Gelée sèche) de lichen. *Fr.*—10 parts of Iceland moss are deprived of bitterness by heating to boiling with a small quantity of water, expressing, and washing with cold water (or as stated above); the residue is exhausted by boiling with water for 1 hour; the decoctions are strained and decanted, mixed with 10 parts of sugar, evaporated, dried, and powdered.—*F. Cod.* It has a gray-brown color.

Medical Action and Uses.—Iceland moss is nutritious, demulcent, and tonic. The first two properties it owes to the starch in its composition, the last to its bitter principle, cetrarin. It increases the appetite, promotes digestion, and improves nutrition. It does not excite the circulation nor constipate, but in excessive doses may occasion nausea and diarrhœa. Its bitterness is said to be perceptible in the milk of nursing women who use it.

This medicine has been employed almost exclusively as a remedy for chronic *pulmonary affections* attended with profuse expectoration and cough and with more or less of the other symptoms belonging to consumption. It acts in these by its nutritious qualities in part, but more usefully by reducing the bronchial secretion, and thereby lessening both the waste of tissue and the fatigue of coughing. The amount of good which the medicine can effect will depend upon how far the *bronchitis*, which it chiefly influences, is simple. If this is accompanied by compression of the lung originating in pleurisy, or consolidation of the lung produced by pneumonia or by tubercle, etc., the influence of the remedy must necessarily be subordinate, or even null. Chronic *diarrhœa* and *dysentery* are sometimes greatly benefited by it. It is usually administered in decoction, but an infusion is sometimes prepared by steeping 3 ounces (Gm. 90) of bruised cetraria in a pint and a half of boiling water for 3 hours, evaporating the liquid with gentle heat to the consumption of one-half, and adding 60 grains (Gm. 4) of extract of liquorice. Of this a fluidounce may be taken every 3 or 4 hours in chronic bronchitis with urgent cough. A decoction made with milk is less bitter, and may be employed as food. Either of the pharmaceutical preparations mentioned above will be found convenient.

CHAMÆLIRIUM.—STARWORT.

Blazing star, Devil's bit, False unicorn-root, E.

The rhizome of Chamælorium (*Veratrum, Linné*) luteum, *Gray*, s. *Cham. carolinianum, Walter*, s. *Helonias lutea, Aiton*, s. *Hel. dioica, Pursh.*

Nat. Ord.—Melanthaceæ.

Origin.—The plant is indigenous to Canada and the United States, where it grows in low grounds west to the Mississippi. The stem is about 18 inches (45 Cm.) high; the leaves are alternate, spatulate below, lanceolate above, smooth; and the small whitish flowers are in a dense terminal raceme, which is rather slender on the barren plant, about 6 inches (15 Cm.) in length. It flowers in May and June.

Description.—The oblique rhizome is about 1 inch (25 Mm.) long and $\frac{1}{4}$ inch (6 Mm.) in diameter, somewhat curved, of a dark gray-brown color, closely annulated from the leaf-scars, on the upper side with a few circular stem-scars, on the lower side

with wiry rootlets or their scars in lines parallel with the leaf-sears. The rhizome breaks with a nearly smooth and horny fracture, and shows on a transverse section the fibro-vascular bundles crowded together near the centre, with a few scattered near the surface, passing into the rootlets. The drug is destitute of odor and has a strongly bitter taste. We have repeatedly found it as an admixture with the commercial rhizome of *Aletris*, from which it is easily distinguished.

Constituents.—Dr. F. V. Greene (1878) extracted from it the bitter principle, which he proposed to call *chamælinin*, and of which over 9 per cent. was obtained. It is prepared by evaporating the cold aqueous infusion with magnesia, washing the dry mass with ether to remove fatty acid, and extracting with absolute alcohol, concentrating, diluting with water, treating with animal charcoal, and evaporating. It is a yellowish-white neutral powder, freely soluble in water and alcohol, the solutions frothing like those of saponin, but insoluble in other simple solvents. With sulphuric acid an orange color is produced, changing to crimson, brown, green, and purple, after which it fades. *Chamælinin* is also soluble in and colored reddish by strong hydrochloric acid, and yellowish-brown by Fröhde's reagent. It has a very bitter taste, and is split by dilute acids into glucose and a resinous body, *chamæliretin*, which is soluble in alcohol and ether, insoluble in water, and is colored brown by sulphuric acid. The so-called *helonin* of the eclectics is the hydro-alcoholic extract of the rhizome.

Medical Action and Uses.—The bitter principle has been made the subject of experiment by Dr. Greene, who concludes that it is “a cardiac poison, and that it produces its effect by virtue of a depressing influence on the pneumogastric centres, and likewise by more or less completely exhausting or paralyzing the heart-muscle by excessive stimulation of the intra-cardiac ganglia.” This observer also found that, like digitalin and senegin, *chamælinin* dissolves the red corpuscles of the blood and disintegrates the white ones (*Phil. Med. Times*, x. 565). Therapeutically, starwort is reputed to be tonic, diuretic, and anthelmintic. An infusion of the rhizome has been found useful in atonic *dyspepsia* and for checking nausea and vomiting. It is also claimed by certain pseudo-physicians to be a “uterine tonic,” “removing abnormal conditions and imparting tone to the reproductive organs.” “It has been somewhat extensively used in the treatment of leucorrhœa, amenorrhœa, and dysmenorrhœa, and likewise with a view of correcting the tendency to repeated miscarriage.” All of these ailments are usually associated with dyspepsia, constipation, and anæmia, and have from time immemorial been cured by bitter tonics, and for a long while with iron and cinchona. It is incredible that a medicine which depresses the heart and the nervous system should remove ailments that depend essentially upon the debility of exhaustion. An infusion of *chamælinin* may be prepared with an ounce of the rhizome to a pint of water (Gm. 32 to Gm. 500), and given in doses of a wine-glassful.

CHARTÆ.—MEDICATED PAPERS.

Papiers sparadrapiques, Fr.; *Medicamentirte Papiere*, G.

This class of preparations was introduced into the last editions of the United States and British Pharmacopœias; they resemble plasters spread upon non-absorbent paper, the process necessarily varying with the nature of the material. Similar preparations have been long in use on the continent of Europe; one which enjoys considerable popularity is—

CHARTA ANTIRHEUMATICA, s. ANTARTHRITICA, s. RESINOSA, Sparadrapum antharthriticum.—Antirheumatic paper, *E.*; Papier antirhumatique. *P.* antiarthritique, *Fr.*; Gichtpapier, *G.*—Melt together 10 parts of resin, 6 parts each of black pitch and turpentine, and 4 parts of yellow wax; strain and spread upon paper.—*P. G.* 1872. The same preparation of the Belgian Pharmacopœia is a cerate containing 1 per cent. of ethereal extract of mezereon. The *Papier au garou* of the French Codex is spread with a cerate containing 3 per cent. (No. 1) or 4 per cent. (No. 2) of ethereal extract of mezereon.

The process of coating such papers is sufficiently described by the pharmacopœial directions. It is, however, sometimes convenient to spread certain cerates or plasters directly upon paper, which may be accomplished by fastening the latter upon a smooth table by means of thin iron ledges attached lengthwise to the margin, then pouring the melted and partly-cooled material upon the paper and spreading it rapidly, using a warm

smooth iron which is long enough to rest upon both ledges; a very uniform and quite thin coating may thereby be obtained. If the material melts to a uniform mass a flat brush may be employed, and care should be taken to apply it in one direction only. Should it be desirable to render the paper more impervious, it may be coated first with well-boiled linseed oil, and then exposed to the air until perfectly dry, after which the material is applied in the manner described. In most cases, however, the intention is to impregnate the paper to some extent with the plaster-like material, which is most readily effected by placing two sheets of the paper upon smooth sheet iron, which is kept warm by means of a low fire or of a sand-bath; some of the melted mass is poured upon the upper sheet, and spread with some pressure by means of a pad about 3 inches in diameter and formed of cotton or tow, which is first covered with tin-foil and then with two or three layers of flannel. When the upper sheet has been thoroughly and uniformly impregnated, it is replaced by another, and this is repeated until the desired quantity of paper has been obtained. The lower sheet of paper is used merely to protect the others from becoming soiled.

The last-described method is followed in making *wax paper*, *Charta cerata*, thin, well-sized paper being impregnated with white wax. It is very convenient for dispensing odorless substances, powders containing volatile oil, etc., for covering soft plasters, and for various other purposes. *Paraffin paper*, prepared in the same way, is employed in a similar manner.

Of an entirely different nature is the nitrate-of-potassium paper which was admitted into the U. S. Pharmacopœia of 1880, and which consists of unsized paper containing minute crystals of potassium nitrate uniformly distributed through the pulp.

CHARTA CANTHARIDIS, U. S.—CANTHARIDES PAPER.

Charta epispastica, Br.; *Charta vesicatoria*.—*Blistering paper*, E.; *Papier vésicant*, P. *épispastique*, *Papier à vésicatoire aux cantharides*, Fr.; *Spanischfliegen-Papier*, G.

Preparation.—White Wax 8 parts; Spermaceti 3 parts; Olive Oil 4 parts; Canada Turpentine 1 part; Cantharides, in No. 40 powder, 1 part; Water 10 parts. Mix all the substances in a tinned vessel and boil gently for 2 hours, constantly stirring. Strain through a woollen strainer without expressing, and by means of a water-bath keep the mixture in a liquid state in a shallow, flat-bottomed vessel with an extended surface. Coat strips of sized paper with the melted plaster, on one side only, by passing them successively over the surface of the liquid; when dry, cut the strips into rectangular pieces.—*U. S.*

Take of White Wax 4 ounces; Spermaceti 1½ ounces; Olive Oil 2 fluidounces; Resin ¾ ounce; Canada Balsam ¼ ounce; Cantharides, in powder, 1 ounce; Distilled Water 6 fluidounces. Digest all the ingredients, excepting the Canada balsam, in a water-bath for 2 hours, stirring them constantly; then strain, and separate the plaster from the watery liquid. Mix the Canada balsam with the plaster melted in a shallow vessel, and pass strips of paper over the surface of the hot liquid, so that one surface of the paper shall receive a thin coating of plaster. It may be convenient to employ paper ruled so as to indicate divisions, each of which is 1 square inch.—*Br.*

The first formula is that of the French Codex, the second a slight modification of it.

Medical Action and Uses.—Cantharides paper forms a neat and efficient blistering agent, and is very convenient when the vesicant action is to be accurately limited, as in blistering over nerves and veins, near the eye, etc. It is, however, less efficient than cantharides cerate when a full and prolonged vesicant operation is desired. Before applying it the skin should be cleansed with warm soap-and-water.

CHARTA POTASSII NITRATIS, U. S.—PAPER OF NITRATE OF POTASSIUM.

Charta nitrata, P. G.; *Saltpetre paper*, E.; *Papier nitré*, Fr.; *Salpeterpapier*, G.

Preparation.—Nitrate of Potassium 20 parts (450 grains); Distilled Water 80 parts (1800 grains or 4 fluidounces). Dissolve the nitrate of potassium in the distilled water. Immerse strips of white, unsized paper in the solution and dry them. Preserve the paper in securely-closed vessels.—*U. S.*

This is the formula of the P. G. 1872; in the recent edition of this work the salt is to be dissolved in 5 parts of water.

Ordinary saltpetre will answer if the paper is to be used for moxas, but for the prep-

aration of *medicated cigarettes* nitrate of potassium free from chloride should be used, and the paper should also be free from chlorine compounds. Such cigarettes are either made in the same manner as ordinary cigars, except that stramonium, belladonna, hyoscyamus, or other leaves are substituted for tobacco, or the nitrated paper is impregnated with other solutions, or simply rolled into a thin tube having the edges fastened with a trace of gelatin; the substance whose smoke is to be inhaled is then introduced and the paper tube ignited at one end, when combustion without flame takes place. The following is a formula for *cigarettes antiasthmiques* which is much employed in France: A decoction is made of 5 Gm. each of the leaves of belladonna, stramonium, digitalis, and sage with 1000 Gm. of water, and strained. 75 Gm. of nitrate of potassium and 40 Gm. tincture of benzoin are added, and into this solution is then introduced, sheet by sheet, one quire of red-tinted absorbent paper, the whole remaining in contact for 24 hours; after which time the paper is dried and cut into rectangular pieces of 10 by 7 Cm., which are formed into tubes by rolling them around a thin cylinder about 1 or 1½ Mm. in diameter and fastening the edge with gelatin.

For forming *mozas* of nitrated paper it is rolled into pretty firm cylinders having a diameter of about ¼ inch, which are afterward cut into pieces of suitable lengths.

Medical Action and Uses.—Under POTASSII NITRAS the uses of this medicated paper are described. It is intended to be burned, while its fumes are inhaled. Since the investigations of Reichert on potassium nitrite (*Amer. Jour. of Med. Sci.*, July 1880, p. 158) there is some reason to think that, besides relieving nervous *asthma* by its irritant action on the bronchial mucous membrane, potassium nitrate may be converted during combustion into potassium nitrite, which, like nitrite of amyl, has an anæsthetic action.

CHARTA SINAPIS, U. S., Br. Add.—MUSTARD PAPER.

Charta sinapisata, P. G.; *Papier sinapise*, Moutard en feuilles, Fr.; *Senfpapier*, G.

Preparation.—Black Mustard, in No. 60 powder, Benzin, Solution of Gutta-percha, each a sufficient quantity. Pack the mustard tightly in a conical percolator, and gradually pour benzin upon it until the percolate ceases to produce a permanent greasy stain upon blotting-paper. Remove the powder from the percolator and dry it by exposure to the air. Then mix it with so much of solution of gutta-percha as may be necessary to give it a semi-liquid consistence; apply the mixture, by means of a suitable brush, to one side of a piece of rather stiff, well-sized paper, so as to cover it completely, and allow the surface to dry. Each square inch (or 6.5 square Cm.) of paper should contain about 6 grains or 40 Cg. of mustard.

Before being applied to the skin the mustard paper should be dipped in warm water for about fifteen seconds.—U. S.

Take of Black Mustard-seeds, in powder, 1 ounce; Solution of Gutta-percha 2 fluid-ounces or a sufficiency. Mix the mustard with gutta-percha solution so as to form a semi-fluid mixture, and having poured this into a shallow flat-bottomed vessel, such as a dinner-plate, pass strips of cartridge-paper over its surface, so that one side of the paper shall receive a thin coating of the mixture. Then lay the paper on a table with the coated side upward, and let it remain exposed to the air until the coating has hardened. Before being applied to the skin let the mustard paper be immersed for a few seconds in tepid water.—Br.

The mustard, previous to powdering, should be deprived of most of its fixed oil by pressure, or the powdered mustard may, with the same end in view, be treated with benzin, as above directed, or with carbon bisulphide. Rigollot (1867), who introduced this preparation, already called attention to the removal of the oil to prevent rancidity, and gave preference to a solution of caoutchouc as the adhesive agent. Hager (1867) regarded a solution of resin as equally useful, and recommended the paper to be first covered with the solution, and the powder to be sifted upon the adhesive layer and pressed, preferably by passing between cylinders suitably adjusted so as to make the stratum uniform and the surface smooth. Following the pharmacopœial directions, by spreading the soft mixture upon paper a layer more uniform in thickness is obtained than by merely passing it over the surface of the former. If the paper has been properly prepared the mustard will adhere well without peeling off on bending.

Medical Action and Uses.—Mustard paper forms a very convenient means of obtaining the effects of a sinapism. Before being applied it should be immersed for a few seconds in warm (not hot) water.

CHELIDONIUM, U. S.—CHELIDONIUM.

Herba chelidonii.—*Chelandine*, Tetterwort, E.; *Chélidoïne*, *Herbe à l'hirondelle*, Fr.; *Schöllkraut*, G.

The herb of *Chelidonium majus*, Linné.

Nat. Ord.—Papaveraceæ.

Origin.—A perennial herb indigenous to Europe and introduced on this continent. It grows in waste places, and flowers from May to September.

Description.—The root is several-headed, fusiform, about $\frac{3}{8}$ inch (15 Mm.) in diameter, branching, somewhat scaly, and of a red-brown color externally, deeply wrinkled, and internally whitish. The stem is 1 to 2 or 3 feet (30, 60, or 90 Cm.) high, light-green, hairy, obtusely angled, with thickened joints, brittle and branching; the leaves are 6 or 8 inches (15 or 20 Cm.) long, and petiolate, the upper ones short-petiolate or sessile, alternate, oblong or oval in outline, lyrate pinnatifid or pinnate, the terminal segment obovate and mostly three-lobed, the others ovate, cut-toothed, or lobed, obtuse, somewhat hairy, light-green above and glaucous underneath. The flowers are in small four- to eight-rayed axillary umbels on long peduncles, have a calyx of two caducous sepals, four obovate yellow petals, about twenty stamens, and produce long linear one-celled and two-valved capsules containing many crested seeds. All parts of the plant contain a bright saffron-colored milk-juice. In the fresh state the odor is rather unpleasant, disappearing almost completely on drying; the taste is bitter and acrid. The herb should be gathered when it begins to flower.

Constituents.—Probst (1838), and shortly afterward Pölex, isolated from celandine two alkaloids, *chelidonine* and *chelerythrine* or *pyrrhopine*; the latter Probst (1840) declared to be identical with sanguinarine, which was proven by Shiel (1855). Chelidonine, $C_{19}H_{17}N_3O_3$, is separated from chelerythrine by ether, in which it is insoluble; it crystallizes in colorless shining plates, has a bitter, afterward acrid taste, and yields with acids colorless salts having an acid reaction and a strongly bitter taste. Probst isolated also *chelidoxanthin*, which crystallizes in small yellow needles, has a bitter taste, is insoluble in ether, sparingly soluble in alcohol, and freely soluble in hot water; it is not altered by acids or alkalis. The alkaloids are combined with malic and *chelidonic acid*, $C_7H_4O_6$ (Lerch, 1846). The latter is slightly soluble in cold water and alcohol, crystallizes from hot water in colorless silky needles having a strongly acid taste and becoming opaque on exposure, is bibasic, decomposes carbonates, dissolves metallic iron and zinc, and yields white lead salts insoluble in water and acetic acid. When boiled with an alkali, acetone and oxalic acid are produced. By an excess of cold alkali it is converted into a yellow acid yielding yellow lead salts and red ferric salts (Lieben and Haitinger, 1873); this new acid is doubtless identical with Zwenger's (1860) *chelidoninic acid*, which was regarded as succinic acid by Walz (1860). The other constituents are those of common occurrence—gum, extractive, albumen, chlorophyll, etc.

Pharmaceutical Preparations.—EXTRACTUM CHELIDONII. The expressed juice is freed from albumen by heating to 80° C. (176° F.), evaporated to a small bulk, mixed with an equal weight of alcohol, strained from the gummy precipitate, and the filtrate evaporated to the proper consistence.—P. G. 1872. It has a dark-brown color.

Allied Plants.—GLAUCIUM LUTEUM, *Scopoli*, s. *Chelidonium Glaucium*, Linné.—Horn poppy, E.; Pavot cornu, Fr.; Hornmohn, G.—A biennial plant, a native of Europe and to some extent naturalized in the United States. It grows mainly near the sea-coast, has pale-green, glaucous, clasping pinnatifid or sinuate toothed leaves, yellow flowers, and linear capsules which are beset with numerous short projections. It is less acrid than celandine; the juice, particularly of the root, is saffron-yellow, and contains, besides sanguinarine, the white alkaloids *glaucine* and *glaucopterine*; the former is in the herb, the latter in the root. *Glaucium corniculatum*, Curtius, has similar properties; the petals are scarlet-red, with a black spot near the base.

Physiological Action and Medical Uses.—The yellow juice which exudes from this plant when wounded was formerly employed, according to the doctrine of signatures, as a remedy for jaundice; and it justified the superstition in so far that by violent purging it relieved cases of the disease depending upon obstruction of the gall-ducts with inspissated bile. In experiments upon animals, and in certain cases of poisoning in man, its effects were those of a violent local irritant, with a special narcotic action upon the nervous system. The fresh plant, as well as the juice, irritates the skin, and the latter is in popular use as a remedy for warts. In many rural districts of Europe the fresh juice is employed as a purgative in jaundice, abdominal dropsy, and inveterate intermittent fever, as well as in scrofula and chronic diseases of the skin. Like other drastic cathartics, it is

sometimes used as a vermifuge. When the fresh juice can be obtained it is given in doses of 30 or 40 drops (Gm. 2–3) or more, in sweetened water or in whey. An extract is used in doses of about 10 grains (Gm. 0.60), and an infusion is made with half an ounce of the plant in a pint of water (Gm. 16 to Gm. 500).

Glaucium luteum is said by Cazin to be a narcotic poison, and he quotes the statement that, having been eaten by mistake, it occasioned delirium and made all objects appear yellow. It is said to be used by the peasants in Provence for the cure of ulcers, bruises, stings, etc., both in man and animals, and to act as an anodyne when applied to hæmorrhoids and spasmodic stricture of the anus. The juice, mixed with white of egg, is used for the latter purposes.

CHELONE.—BALMONY.

Snakehead, Turtlehead, Shellflower, E.; Chelone, Fr., G.

The herb of *Chelone glabra*, *Linné*.

Nat. Ord.—Scrophulariaceæ.

Origin.—The plant is perennial, a native of Canada and the United States south-westward to Texas, grows in wet places, and flowers from July to September. The white corolla is inflated, two-lipped, with the upper lip arched and the mouth a little open; hence the botanical and some of the popular names.

Description.—The stem is 2 to 3 feet (60 to 90 Cm.) high, nearly simple and smooth; the leaves are opposite, nearly sessile, oblong-lanceolate, pointed, serrate, smooth, and shining above. The flowers are in a short, dense terminal spike, and have the lower lip bearded in the throat and the four stamens with woolly filaments and woolly heart-shaped anthers. The plant is inodorous and has a decidedly bitter taste.

Constituents.—The bitter principle appears to be soluble in alcohol and water, but has not been isolated.

Medical Action and Uses.—The extreme bitterness of the leaves of this plant probably led to its medicinal use by the American aborigines. It is not, however, tonic, but laxative or purgative according to the dose of it employed. Like other active cathartics, it is reputed to “act upon the liver.” It is sometimes used as a purgative in jaundice and as an anthelmintic. The dose of the powder is a drachm (Gm. 4). A decoction made with 2 ounces of the fresh herb in a pint of water (Gm. 60 to Gm. 500) may be given in the dose of 2 fluidounces.

CHENOPODIUM, U. S.—CHENOPODIUM.

Fructus chenopodii anthelmintici.—*American Worm-seed, E.; Semences de chénopode anthelmintique, Fr.; Amerikanischer Wurmsamen, G.*

The fruit of *Chenopodium ambrosioides*, *Linné*, var. *anthelminticum*, *Gray*; *Ambrina anthelmintica*, *Spach*; *Orthosporum* (*Chenopodium*, *Linné*) *anthelminticum*, *R. Brown*. *Bentley and Trimen, Med. Plants*, 216.

Nat. Ord.—Chenopodiaceæ.

Origin.—The genus *Chenopodium* is characterized by alternate leaves and bractless flowers with a five-cleft calyx, five stamens, two or three styles, and bearing a one-seeded utricle as fruit. The plants are frequently covered with a white mealiness. The officinal species is never mealy, but viscid glandular. The stem is angular and branched; the leaves are short petiolate, oblong or ovate, narrowed at both ends, remotely toothed; the small greenish flowers are in dense and leafy spikes; the fruit is enclosed in the calyx. The variety differs from the typical form by having usually a perennial root, the leaves more deeply toothed, the lower being often deeply incised, and the dense racemes usually leafless. Both forms are indigenous to the West Indies, Central and South America, and have become completely naturalized in this country, the typical form having also established itself in some portions of Europe and Southern Africa. The variety is cultivated in Maryland with a view of obtaining the oil, and is quite frequent in waste places in the Southern and in some of the Middle States.

Description.—The fruit is about $\frac{1}{2}$ inch (2 Mm.) in diameter, depressed or irregular globular, glandular when viewed with a magnifier, of a dull-green color, assuming a brownish tint on exposure; the thin, friable, but not brittle integuments enclose a vertical seed which is lenticular in shape, obtuse at the edge, brownish-black and glossy, and has the embryo strongly curved around the albumen. The fruit has a peculiar aromatic somewhat terebinthinate odor and a bitterish and pungent taste. The fruit of *Chen.*

ambrosioides cannot be distinguished from the officinal, except by its weaker and rather pleasanter odor.

Constituents.—American wormseed has not been analyzed; its medicinal importance is due to volatile oil (see *OLEUM CHENOPODII*), which is the only preparation for which the fruit is used.

Allied Species.—Several European pharmacopœias recognize the herb of *Chen. ambrosioides*, *Linneé*, which is known as *Herba botrys mexicanæ*; Mexican tea, *E.*; Thé du Mexique, des Jésuites, *Fr.*; Mexikanisches Traubenkraut, *G.*

CHEN. BOTRYS, *Linneé*.—Jerusalem oak, Feather geranium, *E.*; Chénopode à grappes, *Fr.*; Traubenkraut, *G.*—It is indigenous to Asia and Europe, and naturalized to some extent in North America. It is glandular pubescent, has oblong sinuate-pinnatifid leaves and leafless cymose racemes of greenish flowers, and is strongly aromatic.

CHEN. BONUS-HENRICUS, *Linneé*.—Good King Henry, *E.*; Bon Henry, *Fr.*; Guter Heinrich, *G.*—A European plant somewhat naturalized here. It is slightly mealy, and has triangular halberd-shaped leaves which have a mucilaginous saline taste.

CHEN. ALBUM, *Linneé*.—Pigweed, Lamb's quarters, *E.*; Ansérine sauvage, *Fr.*; Weisser Gänsefuß, *G.*—A variable mealy annual, common in cultivated ground. The leaves vary between rhombic-ovate and lanceolate and are angulate-toothed, the upper ones often entire. The taste is mucilaginous and saline.

Medical Action and Uses.—All parts of the plant producing worm-seed possess anthelmintic properties, and were long used by the Southern negroes and others as a vermifuge for *lumbricoid* worms, the expressed juice and the seeds being most commonly employed. These have been supplanted by the oil (*Oleum chenopodii*). The fresh expressed juice may be given in doses of a tablespoonful (Gm. 16) two or three times a day. A decoction made by boiling an ounce of the leaves in a pint (Gm. 30 in Gm. 500) of milk or water has also been used. The bruised or pulverized seeds may be given in an electuary in doses of 20 or more grains (Gm. 1.30) three times a day. Carbonate of iron may be advantageously added to this preparation. After the anthelmintic has been used for several days a purgative dose of castor oil should be administered.

Chenopodium ambrosioides and *C. vulvaria* are used in Europe for various nervous derangements, both internally and topically. *C. Bonus-Henricus* is a popular remedy in Europe for many local pains. The contused plant, mixed with butter, is applied. *C. botrys* is reputed to be a stimulant expectorant and antispasmodic, and *C. olidum* to have similar properties.

CHIMAPHILA, U. S.—CHIMAPHILA.

Pipsissewa, Prince's pine, Wintergreen, *E.*; *Herbe de pyrole ombellée*, *Fr.*; *Doldenblüthiges Harnkraut*, Wintergrün, *G.*

The leaves of *Chimaphila umbellata*, *Nuttall*, s. *Chim. corymbosa*, *Pursh*, s. *Pyrola umbellata*, *Linneé*. Bigelow, *Med. Bot.*, ii. 21; Woodville, *Med. Bot.*, v.; Bentley and Trimen, *Med. Plants*, 165.

Nat. Ord.—Ericaceæ, Pyroleæ.

Origin.—The genus is characterized by flowers having five petals, ten stamens with the filaments enlarged in the middle and the anthers conspicuously two-horned; the short style, with the disk-like and five-lobed stigma, is nearly immersed in the top of the ovary; the capsule is five-celled and many-seeded. The officinal species is a low shrub, 4 to 8 inches (10 to 20 Cm.) high, bearing the leaves near the summit of the stem, and a terminal peduncle with five or six wax-colored flowers in a corymbose umbel. It is indigenous to North America, Northern Asia, and Northern and Central Europe; is found in dry woods, and flowers in June and July. 2 parts of the fresh yield about 1 part of airy leaves.

Description.—The leaves are 1 to 2 inches (25 to 50 Mm.) long, on very short petioles, oblanceolate and sharply serrate above, with the base wedge-shaped and entire, leathery, upper side dark-green and glossy, paler beneath. They are nearly inodorous, and have a sweetish afterward astringent and bitterish taste.

The closely-allied *Chim. maculata*, *Pursh*, spotted wintergreen or pipsissewa, with lanceolate or ovate-lanceolate and toothed leaves, which are variegated with white on the upper surface, is indigenous to North America, and is used like the preceding. The leaves have the same constituents as the *Pyrolas*, but contain citric instead of malic acid (*E. N. Smith*).

Constituents.—Besides the widely-diffused principles sugar, gum, etc., *S. Fairbank* (1860) found tannin, and obtained 5.24 per cent. (of the dry leaves?) of ash. The tannin

amounts to 4.15 per cent (Bowman, 1869). On distilling the stems with water, golden-yellow crystals of *chimaphilin* are obtained in the neck of the retort; these are inodorous and tasteless, slightly soluble in water and freely soluble in alcohol, ether, chloroform, and the fixed and volatile oils. It may also be obtained from the tincture (of the leaves alone?) made with diluted alcohol by agitating it with water. Zwenger and Himmelmann (1864) isolated from the leaves *arbutin*, which, together with tannin, was found by J. Oxley (1872) and E. N. Smith (1881) in several other ericaceous plants. (See *EPIGÆA*, *GAULTHERIA*, and *UVA URSI*.)

Off. Prep.—Extract *chimaphilæ fluidum*, *U. S.*

Allied Plants.—1. *Pyrola rotundifolia*, *Linneé*; 2. *P. chlorantha*, *Suartz*; and 3. *P. elliptica*, *Nuttall*.—Shinleaf, Wintergreen, *E.*; Pyrole, *Fr.*; Waldmangold, *G.*—These species are indigenous to North America, the first one also to Europe and Asia. They have thin rhizomes, a cluster of radical petiolate leaves, and simple racemes of nodding wax-like flowers. The leaves are leathery, orbicular, and glossy (in 1), short-petiolate, suborbicular, and dull-green (in 2), or thin, not glossy, elliptic or oval-obovate (in 3); in odor and taste they resemble the preceding. E. N. Smith (1881) showed them to contain arbutin, ericolin, ursin, tannin, malic acid, gum, sugar, albumen, and a trace of volatile oil.

Medical Action and Uses.—The fresh bruised leaves of pipsissewa applied to the skin cause redness, and even vesication. Internally, it is diuretic, tonic, and astringent, and, like *uva ursi*, darkens the urine in consequence of the tannin it contains. Indeed, in all its operations it closely resembles *uva ursi*. It was used by the natives and by the early settlers of this country for *rheumatism* and for *nephritic disorders*. The former disease in the joints was treated with fomentations or poultices of the leaves, while a hot decoction of them was administered internally, to the production of sweating. In cases of scanty or suppressed secretion of *urine* it was often resorted to, as well as in *gravel* and *hematuria* from various causes. The cure of many cases of *dropsy* was attributed to its use, and the evacuation of the fluid through the kidneys in other cases depending upon incurable organic lesions. Physicians of sound judgment have testified to its usefulness in *scrofula* of the glands and skin, both as an internal remedy and as an application to scrofulous ulcers. In the treatment of dropsy and of scrofula the generally superior efficacy of other medicines should not cause this one to be overlooked. *Chimaphila* has also been prescribed in the treatment of *intermittent fever*, *chronic diarrhæa*, *leucorrhæa*, and *gleet*, and *P. rotundifolia* has been similarly employed. The best form of the medicine is the decoction or the fluid extract.

CHINOIDINUM, *U. S.*—CHINOIDIN.

Chinoidinum, *P. G.*; *Chinoidina*, *Quinoidina*.—*Quinoidine*, *E., Fr.*; *Amorphous quinine*, *E.*; *Quinine amorphe*, *Fr.*; *Chinoidin*, *G.*

A mixture of alkaloids, mostly amorphous, obtained as a by-product in the manufacture of the crystallizable alkaloids from cinchona.

Preparation.—In the preparation of sulphate of quinine, cinchonine, and the other alkaloids from cinchona-bark there remains finally a mother-liquor from which crystallizable salts cannot be readily prepared; this mother-liquor, on being precipitated with soda, yields chinoidine, which is further purified by redissolving it in diluted hydrochloric acid, precipitating by ammonia, washing, and drying. Blews (1874) proposed to effect the purification by adding sodium hyposulphite to the neutralized solution in dilute sulphuric acid, then filtering, warming, and finally precipitating by soda.

Properties.—Chinoidine is met with in commerce in cylindrical rolls or in masses having a more or less deep-brown (brownish-black or almost black, *U. S.*) color and a resin-like appearance. At a low temperature it is brittle and breaks with a glossy conchoidal fracture; exposed to the summer heat, it gradually assumes the shape of the vessel in which it is kept. When heated it becomes plastic, then melts, and at a still higher heat burns with a bright flame. It is almost insoluble in water, and has only a slight taste, faintly bitter on mastication, but not bitter, as stated by both the *U. S. P.* and *P. G.* It is freely soluble in alcohol, the solution showing an alkaline reaction, dissolves in chloroform and in diluted acids, and also more or less in ether and benzol. The solutions have a very bitter taste and are dextrogyre. The alcoholic solution is precipitated by water; the solution in diluted acids on being treated with chlorine-water in excess and ammonia assumes an emerald-green color, and with chlorine-water, potassium ferrocyanide, and ammonia, added successively, a red color closely resembling quinine in these tests.

Tests.—If chinoidine be triturated with boiling water, the liquid after filtration should be clear and colorless, and should remain so on the addition of an alkali (absence of alkaloidal salts). On ignition chinoidine should not leave more than 0.7 per cent. [0.5 or 0.7 per cent. *P. G.*] of ash.—*U. S.* “One part of chinoidine should yield a clear solution and leave only a scanty residue on being treated with a cold mixture of 1 part of acetic acid and 9 parts of water (absence of resins, etc.); it should also yield a clear solution in the cold with 9 parts of alcohol sp. gr. .832 (absence of gummy matter, etc.).”—*P. G.*

Composition.—The alkaloidal nature of chinoidine was first observed by Sertürner. Subsequently, Henry and Delondre, Duflos, Winckler, and others showed that this amorphous mass still contained quinidine (then confounded with quinine) and cinchonine. Freed from the crystallizable alkaloids, Liebig regarded chinoidine as quinine rendered amorphous by the influence of heat and of chemicals. Hesse (1877) has shown that aside from the crystallizable bases which may be present chinoidine has been formed by the condensation or polymerization of their molecules.

Diconchinine, $C_{40}H_{46}N_4O_3$, is the principal constituent of chinoidine, of barks containing much quinine, and quinidine; it is amorphous and does not yield quinicine, but resembles the two cinchona alkaloids in the fluorescence of the sulphuric acid solution and in its behavior to chlorine and ammonia (green coloration). The chinoidine of barks yielding much cinchonine or cinchonidine contains amorphous *dicinchonine*, $C_{38}H_{44}N_4O_2$, which is not easily freed from diconchinine. *Dihomocinchonine*, $C_{38}H_{44}N_4O_2$, like diconchinine, has also a right rotation.

Pharmaceutical Preparations.—CHINOIDINÆ BORAS, BORATE OF CHINOIDINE. De Vrij (1881) gives the following directions: Heat 20 parts of chinoidine, 10 parts of boric acid, and 200 parts of water to incipient boiling and filter through moist cotton; heat the clear liquid to boiling, again filter from the resinous matter, and repeat this operation until no more matter is separated on boiling; evaporate to 20 parts, set aside over night at a temperature not exceeding 15° C. (59° F.), filter from the boric acid, and evaporate. It forms brown-yellow transparent scales or a yellowish powder, becomes damp on exposure, has an alkaline reaction and a bitter taste, and yields with 3 parts of cold water a perfectly clear dark-yellow solution. Dissolved in 10 parts of water, the solution becomes cloudy on boiling, but clear again on cooling.

CHINOIDINÆ CITRAS, CITRATE OF CHINOIDINE, made by dissolving chinoidine in an aqueous solution of citric acid and evaporating, forms transparent red-brown scales soluble in water.

CHINOIDINÆ HYDROCHLORAS, HYDROCHLORATE OF CHINOIDINE, is prepared by saturating warm diluted hydrochloric acid with chinoidine, filtering, and evaporating; it is a yellow or brown-yellow hygroscopic powder.

TINCTURA CHINOIDINI, TINCTURE OF CHINOIDINE. Dissolve 10 parts of chinoidine in a mixture of 85 parts of alcohol sp. gr. .894 and 5 parts of hydrochloric acid. It is dark-brown, transparent in thin layers, very bitter, and without distinctive odor; on mixing it with an equal bulk of water and of ammonia the chinoidine is precipitated and the liquid becomes yellowish.—*P. G.*

Medical Action and Uses.—This preparation is officinal in the U. S. P., and also in the P. G. It was first employed in Philadelphia (1824) in the treatment of *intermittent fever*, and regarded as not less efficacious in the cure of that disease than quinia, provided it were given in larger doses. It was made officinal in 1830, but in the following decade was abandoned, probably because of its uncertain composition and its adulterations. It, however, continued to be used in Europe as a substitute for quinia, partly on account of its cheapness and partly because it was less bitter. In 1874 we said of it: “Its slight bitterness renders it appropriate for administration to children and others who object to the taste of the sulphate” (*Therapeutics*, 4th ed., i. 551). Its composition continues to be an objection to the medicine, which, however, is counterbalanced by its cheapness, which has become a serious consideration since the commercial value of quinine has been enhanced by its wasteful employment in non-malarial diseases. In 1878, Vinkhuysen (*Practitioner*, xx. 81) drew the following conclusions regarding it from his own observation: 1. “The only malarious disease in which chinoidine cannot be employed in place of quinine is pernicious fever, for it requires more time to act than quinine. 2. In all forms of pure malarial intermittent fever it is no less powerful than quinine, but acts more slowly. It must therefore be given in larger doses and at longer intervals before the paroxysm than quinine. 3. It may be taken during the fit without exciting any unpleasant feeling. 4. It never causes noises in the ears. 5. Persons

liable to suffer from the toxic effects of quinine can take chinoidine without discomfort, and yet obtain a similar therapeutical result. 6. In chronic cases its influence is greater than that of quinine. 7. Its tonic action is similar to, and perhaps greater than, that of quinine. 8. Its action in cases of masked or larval malarial disease, and especially in rheumatic affections due to malarial influences, is incomparably greater than that of quinine." In 1882, Hagens of Dantzic, in an exhaustive examination of the various surrogates for quinine (*Zeitschrift f. klin. Med.*, v. 242), and from a clinical point of view, reaches almost identical conclusions respecting the citrate of chinoidine, admitting, however, that it is apt to provoke vomiting unless associated with proper correctives. According to Nothnagel and Rossbach, its dose must be two or three times greater than that of the quinine salts; and Bernatzik states the dose at one-half greater than that of quinine. Burdel, whose field of practice is in a very malarial region, states the dose for an adult at from 7 to 15 grains, and for very young children 2 or 3 grains, recommending it to be given in strong coffee highly sweetened. He points out its special merits as being exhibited in mild and also in chronic cases of the disease, especially where the malarial cachexia is marked (*Bull. de thérap.*, c. 142). Similar testimony abounds. There can be no doubt that this preparation might be very usefully substituted in many cases in which the bitterness of quinine or its cost renders it objectionable.

CHIRATA, U. S., Br.—CHIRATA.

Chiretta, U. S. 1870.—*Chiretta*, E., G.; *Chirette*, Fr.; *Ostindischer Enzian*, G.

The entire plant *Ophelia* (Swertia, Wallich) *Chirata*, *Grisebach*, *Agathotes* (Gentiana, Roxburgh) *Chirayta*, Don. Wallich, *Plant. Asiat.*, iii. 252; Bentley and Trimen, *Med. Plants*, 183.

Nat. Ord.—Gentianaceæ.

Origin.—The plant is an annual, and indigenous to the mountainous portions of Northern India, where it grows at an elevation of from 5000 to 9000 feet, and is collected when the fruit begins to form. It has long been in use in India, and became known in England as a medicine about 1839.

Description.—It is met with in flattened bundles about 3 feet (90 Cm.) long, tied with a thin slip of bamboo, and has a pale purplish-brown color. The simple and tapering root is about 3 inches (75 Mm.) long. The stem is 3 to 5 feet (0.9 to 1.5 M.) long, cylindrical below, slightly quadrangular above, much branched, smooth, and slightly thickened at the nodes. The leaves are opposite, closely sessile, ovate or ovate-lanceolate, entire at the margin, and five-nerved; in the outer layer of the bundles they are usually broken off, leaving the stems almost bare. The flowers are numerous and small, in loose axillary racemose cymes, on the upper branches often single, stalked, with a deeply four-lobed calyx and corolla, the latter upon each acute lobe with a pair of fringed scales; stamens four. The fruit is an ovate capsule, tapering above into the two styles and projecting but little from the persistent calyx and corolla. The seeds are very numerous, minute, and angular. The drug is inodorous and has a purely and persistently bitter taste.

Constituents.—The older analyses failed to isolate the active principles of chirata, and demonstrated only the presence of the common constituents of plants and the almost total absence of tannin. Henry Höhn (1869) succeeded in isolating two distinct bitter principles—*ophelic acid*, $C_{13}H_{20}O_{10}$, and *chiratin*, $C_{26}H_{48}O_{15}$, the former of which was obtained as a brown, very hygroscopic, amorphous mass which is readily soluble in water, alcohol, and ether, has a slightly acidulous afterward intensely bitter taste, precipitates cuprous oxide from Trommer's solution, and produces with the lead acetates yellow precipitates; a crystalline salt could not be obtained. Chiratin forms a pale-yellow powder, which, though hygroscopic, is not freely soluble in cold water, but dissolves readily in alcohol and ether, and has a neutral reaction to test-paper and an intensely bitter taste. Its aqueous solution produces a flocculent white precipitate with tannin, and is not affected by Trommer's solution. When boiled with diluted hydrochloric acid it is split into *ophelic acid* and *chiratogenin*, $C_{13}H_{24}O_8$, which is yellowish-brown, amorphous, bitter, nearly insoluble in water, soluble in alcohol, not precipitated by tannin, and not affected by Trommer's solution. It is not improbable that chiratogenin may exist in the drug. The presence of a yellow crystalline wax-like substance and of some tannin was also observed. Dried at 100° C., the stems yielded 3.7 and the leaves 7.5 per cent. of ash, which is mainly composed of potassa, lime, and magnesia, combined with carbonic and phosphoric acids.

Substitutes.—Several species of *Ophelia* and allied genera are known in India as *chirata*, and are distinguished from the officinal drug as *puharee* (hill), *dukhunee* (south-ern), *oolu* (purple), and *meetha* (sweet) *chirata*; they appear to be indiscriminately collected and sent to Bombay, where, according to Dymock, the drug is garbled. Prof. Bentley (1874) met with such a substitution (probably *Ophelia angustifolia* or *O. pulchella*, Don), which had the stem obscurely quadrangular below and evidently four-sided and winged above, the leaves narrow and tapering to both ends, the leaf-scars not prominently marked, the flowers larger, the woody circle of the stem thicker, and the infusion less bitter than the true *chirata*.

Off. Prep.—Infusum *chiratae*, Br.; Tinctura *chiratae*, U. S., Br.

Medical Action and Uses.—In Hindostan this medicine is held to be *stomachic*, tonic, anti-periodic, cholagogue, and deobstruent, as well as efficient in chronic *bronchitis*. In truth, it possesses virtues very similar to those of gentian and other simple bitters. The dose of *chirata* is about 20 grains (Gm. 1.30). An infusion may be made with half an ounce of *chirata* to a pint of boiling water (Gm. 16 to Gm. 500), or this preparation may be reduced by boiling for 20 minutes. *Dose*, 1 or 2 fluidounces (Gm. 60), three times a day.

CHLORAL, U. S.—HYDRATE OF CHLORAL.

Chloral hydras, Br. Add.; *Chloralum hydratum*, P. G.; *Aldehydum trichloratum*.—*Chloral*, *Trichloraldehyd-hydrate*, E.; *Hydrate de chloral*, Fr.; *Chloralhydrat*, G.

Formula $C_2HCl_3O.H_2O$. Molecular weight 165.2.

Chloral should be preserved in glass-stoppered bottles in a cool and dark place.

Formation and Preparation.—Chloral was discovered by Liebig (1832), and its production and composition were soon after determined by him and by Dumas. The results of these investigations prove that when dry chlorine is passed into absolute alcohol, aldehyd and hydrochloric acid are first formed: $C_2H_6O + Cl_2 = C_2H_4O + 2HCl$. By the continued action of dry chlorine gas 3 atoms of hydrogen are abstracted from the aldehyd, with the formation of hydrochloric acid, and are replaced by 3 atoms of chlorine, producing chloral; the reaction is explained by the following equation: $C_2H_4O + 3Cl_2 = 3HCl + C_2HCl_3O$. Wurtz and Vogt regard the reaction as much more complicated. Other products of decomposition are formed in smaller quantities, and necessitate the subsequent purification of the chloral. The yield is very materially reduced if water be present, in which case a portion of the aldehyd at first produced is converted into acetic acid ($C_2H_4O + H_2O + Cl_2 = C_2H_4O_2 + 2HCl$), and this acid, reacting with some alcohol, forms acetic ether, which is not transformed into chloral by the action of chlorine. In preparing chloral, therefore, the materials reacting upon one another must be as nearly free from water as they can be obtained. Chlorine gas is generated in the usual manner, and passed first into a Woulf's bottle, where some of the moisture is condensed; then over chloride of calcium or through sulphuric acid, by which it is completely dried; and finally into the absolute alcohol, which is kept cool as long as the chlorine gas is rapidly absorbed, but after a few days requires to be warmed, the heat being slowly increased, until at the end of the process it has reached 60° to 70° C. (140° to 158° F.). The whole process requires about 2 weeks (for 600 Gm. of alcohol 3 days, Dumas); but if larger quantities of alcohol be operated upon a longer time is required. In the experience of Dr. Squibb (1870), 92 pounds of alcohol required the continuous generation of chlorine gas for 28 days, using about $1\frac{1}{4}$ tons of a mixture of manganese binoxide and common salt, and yielded about 160 pounds of crude chloral. Large quantities of hydrochloric acid gas containing some chloral escape during the latter part of the process, and if passed through a reversed condenser the vapors of the latter will be condensed and returned to the vessel. Kraemer observed (1874) that the ethereal liquid which accumulates beneath the hydrochloric acid is a mixture of the *chlorides of ethylene* and *ethylidene*.

Crude chloral for its purification should be treated first with about its own weight of strong sulphuric acid, by which the hydrate and alcoholate of chloral are decomposed and colorless chloral separates as an oily layer, which is at once rectified over some burned lime. To avoid combustion the lime must be completely covered by the liquid. Dr. Squibb prefers to distil the chloral directly from the sulphuric acid, to combine the distillate partly with water, rectifying it over a mixture of lime and calcium carbonate, and hydrating this second distillate completely by adding the necessary quantity of water, ascertained by calculation from the weight of the first distillate (82 parts require 10 parts

of water); while still hot the mass is poured upon plates covered with a bell-glass and allowed to crystallize.

Properties.—Chloral (anhydrous) is a colorless, thin, oily liquid of a peculiar pungent, irritating odor and caustic taste. It has the density 1.502 at 18° C. (64.4° F.), boils at 99.1° C. (210.4° F.), and is gradually, or sometimes rapidly, converted into *insoluble chloral* or *metachloral*, which is a white mass or powder of the same elementary composition as chloral, but of a much weaker odor, and at about 180° C. (356° F.) distils without melting, and becomes again liquid and soluble in water. The change into the insoluble condition is prevented by the addition of a little chloroform (Markoe, 1870).

(Chloral hydrate is met with in white crystalline masses or in separate colorless, oblique-rhombic crystals of a saccharoid aspect, and attracts moisture in a damp atmosphere, but in a nearly dry atmosphere evaporates slowly without liquefying. It has a peculiar aromatic and somewhat irritating odor, the pungency of which is increased with the temperature, and a bitterish caustic taste. Its vapors are but slightly affected by the vapors of ammonia, except at a somewhat elevated temperature, when white clouds are produced. It fuses at about 58° C. (136° F.) to a clear, colorless liquid having the spec. grav. 1.575, and congealing again to a crystalline mass at about 50° C. (122° F.) (between 35° and 50° C. = 95° and 122° F., *U. S.*). At about 78° C. (172° F.) it begins to yield vapors of water and of anhydrous chloral, and it boils near 95° C. (203° F.), and evaporates without leaving any residue. It is soluble in 4 parts of chloroform and in less than its own weight of water, alcohol, or ether. Chloral which has been insufficiently hydrated contains the insoluble modification, and is therefore not completely soluble in water. It dissolves in petroleum benzin, benzol, and carbon bisulphide, and may be readily obtained in crystals from the hot solutions. It is soluble in glycerin, liquefies in contact with camphor and carbolic acid (see below), and forms solutions with fats and volatile oils (Jehn, 1874). The solution of chloral hydrate in strong alcohol has and retains a neutral reaction, but when dissolved in water it slightly reddens blue litmus-paper; it is, however, not precipitated by nitrate of silver (absence of hydrochloric acid); exposed to a damp atmosphere or when kept in aqueous solution, it acquires a permanent acid reaction. Treated with warm soda or other alkaline hydrate, chloral is decomposed into chloroform and formate; $\text{C}_2\text{HCl}_3\text{O} + \text{KHO}$ yields $\text{CHCl}_3 + \text{KCHO}_2$.

On adding to the aqueous solution of chloral contained in a test-tube water of ammonia, and a few drops of test solution of nitrate of silver, a silver mirror will be obtained upon the glass. An aqueous solution, treated with test solution of sulphide of ammonium, gives a reddish-brown precipitate. Chloral hydrate which has acquired an acid reaction may be purified by recrystallization from hot benzin or carbon bisulphide; should the decomposition have proceeded further, it is best to treat with strong sulphuric acid, etc., as in the purification of crude chloral.

Tests.—The presence of chloral alcoholate is indicated by the combustion which takes place on heating a sample upon platinum-foil over a flame. Smaller quantities are detected by the turbidity resulting from the production of iodoform if a strong aqueous solution is warmed with a slight excess of potassa solution, iodine being then added as long as it is decolorized. On cooling, microscopic crystals of iodoform will separate. The presence of various organic impurities is detected by warming the chloral hydrate with sulphuric acid, which will then acquire a brown color. If decomposition has set in, the aqueous solution of chloral hydrate on being acidulated with sulphuric acid will readily decolorize a weak solution of potassium permanganate and cause a white precipitate with nitrate of silver. The decomposition of chloral hydrate by alkalis affords a means of estimating its value: when perfectly pure, 100 grains of it, dissolved in an ounce of water and mixed with 30 grains of slaked lime and distilled, yield not less than 70 grains of chloroform. Moist chloral hydrate yields less in proportion to the excess of moisture; chloral alcoholate produces only 60 per cent. of chloroform. V. Meyer and Heffter (1873) estimate the purity of chloral from the amount of formic acid produced by warming the solution of chloral hydrate with an excess of normal solution of soda and determining the excess of soda volumetrically by an acid. Pure sodium hydrate will decompose 4.1375 times its weight of pure chloral hydrate.

“Chloral should be dry, and should not readily attract moisture in ordinarily dry air; when dissolved in diluted alcohol it should not redden blue litmus-paper (absence of acids), nor be precipitated upon addition of a few drops of nitric acid and of test solution of nitrate of silver (absence of hydrochloric acid). Warmed in contact with an equal volume of sulphuric acid, it liquefies, but should not blacken, and when vaporized by heat no residue should remain. It should not dissolve in less than four times its weight

of chloroform at 15° C. (59° F.) (difference from alcoholate). A portion in a test-tube containing a fragment of broken glass held in water nearly boiling should boil at about 97° C. (206.8° F.) (difference from alcoholate, which boils at 115° C. (239° F.), and evidence of due hydration). If 1 Gm. be dissolved in 2 Cem. of distilled water, the solution warmed, and about 8 Cem. (or a slight excess) of solution of potassa added, the mixture filtered clear through wet filter-paper, and the filtrate treated with test solution of iodine until it is yellowish, no yellow crystalline precipitate (iodoform) should appear even after standing half an hour (absence of alcoholate of chloral).”—*U. S.*

Pharmaceutical Preparations.—CHLORAL HYDRATE AND CAMPHOR. In 1873 attention was drawn to the fact that if powdered camphor be triturated with an equal weight of chloral hydrate a colorless liquid of syrupy consistence is obtained, which has since been used under the name of *camphorated chloral*. E. C. Saunders (1876) regards it as a simple solution, camphor being the solvent; but from its optical behavior Cazeneuve and Imbert (1880) consider it a true chemical compound. It is soluble in alcohol, ether, chloroform, glycerin, fixed oils, and in aqueous solutions of chloral; but it is decomposed by water, chloral hydrate being dissolved and camphor precipitated.

CHLORAL HYDRATE AND PHENOL, equal parts of each, yield a liquid which, after impregnating cotton with it, has been recommended for relief in toothache. J. B. Garrison (1881) prefers for this purpose the firm and short cotton from the cottonwood tree, *Populus canadensis*, *Michaux*; when saturated with the liquid it is known as *chloro-carbolated cotton*.

CHLORAL HYDRATE AS A SOLVENT.—R. F. Fairthorne (1874) observed that solutions of chloral hydrate in water or glycerin will dissolve morphine, veratrine, and other alkaloids, and suggested a class of preparations which he named *chloral-glycerites*, the basis of which is a solution of 1 drachm of chloral hydrate in half a fluidounce of glycerin.

Off. Prep.—Syrupus chloral, *Br. Add.*

Physiological Action.—*On Animals:* Chloral is hypnotic and anæsthetic. Many animals are very susceptible to its action. 1½ grains hypodermically administered to a rabbit caused a lethargic sleep lasting 9 or 10 hours. In frogs a grain rapidly induced insensibility, coma, and death, immediately preceded by spasm or convulsion. In general, the sleep produced in animals by chloral is not profound, but prolonged, and resembles natural sleep. It lowers the pulse- and respiration-rates and lessens the blood-pressure. It reduces the temperature so considerably that of two animals to which equal poisonous doses are given, if one be kept warm artificially, and the other exposed to the air, the former will be saved, but the latter will die. These are the results when chloral is administered by the stomach or hypodermically. When it is injected into the veins the effect will vary with the dose employed; the heart and lungs may simultaneously and suddenly cease to act, or the latter may be first arrested, or the action of both may be interfered with in various degrees. But in general the respiratory movements cease before the arrest of the heart. The heart's muscles appear to be partially paralyzed, and its cavities become more distended with blood at each pulsation. If the animal survives the heart recovers slowly and irregularly its normal action. Meanwhile, the blood accumulates in the blood-vessels as well as in the heart, embarrassing still further respiration and oppressing the cerebro-spinal nervous centres. In all these organs, including the heart, and in the muscles also, the vessels are gorged with blood. This fluid is not altered unless chloral is directly mixed with it; in that case its red corpuscles may be disorganized. Observation of its effects upon animals appears to show that chloral in slowly-poisonous doses interferes with or arrests the functions in the following order: 1, those of the brain; 2, those of the voluntary muscles; 3, those of the respiratory apparatus; 4, those of the heart. Throughout the series the blood grows more and more unfit to sustain life.

The experiments of Brown-Séquard show that anhydrous chloral applied to the skin of animals acts more slowly than chloroform, but induces death much more frequently, as well as pulmonary, renal, and intestinal hæmorrhages—that it causes diarrhœa and diabetes, and is absorbed from the skin in larger quantities than chloroform. The mode in which this chloral, so applied, causes death is by producing general insensibility, relaxation, infrequent respiration, and gradual extinction of the heart-beats (*Times and Gazette*, Feb. 1881, p. 163)—in a word, the effects of chloral hydrate taken internally.

On Man: Applied in its pure state to the sound skin, it occasions a slight redness, but it acts as a powerful irritant upon the derm and upon wounds, even occasioning eschars, and it excites pain in healthy mucous membranes. A warm saturated solution of chloral in water is said to have acted as a caustic upon the skin of the temple, and a paste com-

posed of chloral and finely-powdered tragacanth to have vesicated the skin of the forearm. Its taste, even in a watery solution, is somewhat acrid and bitter, causing a sense of burning in the throat, and sometimes in the stomach also, and producing more or less salivation. In enema it occasions heat and irritation in the rectum, and its subcutaneous injection is not only painful, but is apt to be followed by sloughing.

Like opium, chloral allays pain and produces sleep, but less perfectly than opiates. It seldom produces the untoward effects of opium, such as nausea, dryness of the fauces, constipation, anorexia, dysuria, headache, giddiness, or malaise; nor, except in very large doses, does it occasion anaesthesia. Indeed, the effects of occasional and appropriate doses closely resemble natural sleep, except that the face is flushed and the pupils are more or less contracted; the patient may sometimes even be temporarily awakened to take food or obey a call of nature without interfering permanently with its soporific action. As in natural sleep, respiration and circulation are retarded and the temperature is slightly lowered. The pupils are contracted and insensible to light. Exceptions to these statements may be found in certain cases in which the sleep is restless or unrefreshing, or in which a state of delirious excitement exists, or in which there is subsequently experienced a degree of dulness or headache or sick stomach, or a partial loss of power in the limbs. Numerous cases are reported of violent delirium produced by this preparation (Kane, *Philad. Med. Times*, xi. 225). According to Bouchut, children can take chloral with much less danger than adults.

Like chloroform, chloral sometimes produces poisonous, and even fatal effects, without its being possible to explain them by its excessive dose or by any special condition of the patient. Death has resulted from the use of even 10 grains of the drug. The phenomena of acute chloral-poisoning usually denote failure of the heart's action. They include faintness, feeble pulse, fluttering heart, paralyzed and cold extremities, a sense of sinking, pallor, and partial lividity of the face; in a word, the phenomena of syncope. In other cases narcotism and asphyxia occur, especially where the dose has been immoderate, as in a case in which death took place in about 4 hours after 480 grains of chloral hydrate had been taken with suicidal intent. The breathing is then apt to be stertorous and labored and the limbs blue and cold. The pulse and respiration are usually quickened, but not greatly unless danger is imminent. The breath exhales a sweet odor. In some cases the toxic effects come on suddenly in the midst of quiet sleep, the patient falling into collapse, with convulsions, presently ending in death. Or there may be no convulsion, and death is preceded only by hurried breathing and fluttering of the heart. Sometimes recovery takes place after enormous doses, such as in one case 165 grains, in another 350 grains. In a third case 1 ounce of the drug produced a sleep of 48 hours, after which the patient recovered (*Boston Med. and Surg. Jour.*, July, 1882, p. 22); and in a fourth case 28 Gm. (nearly an ounce) were taken soon after a meal without very serious consequences (*Bull. de therap.*, cv. 516). The post-mortem lesions consist of venous congestion of the brain and lungs, distension of the heart with dark and mostly liquid blood, and sometimes dark congestion and hyperæmia of the gastric blood-vessels.

A state of chronic disorder, which may be called chloralism, and is sometimes very persistent, comprises many of the following phenomena: mental hebetude and irritability, hallucinations, insanity, emotional excitability and obstinate insomnia, loss of memory, with physical incapacity for exertion, and extreme prostration on attempting it; uncertainty of movement and a tendency to fall forward, or absolute inability to stand or walk or perform various co-ordinated movements, as writing, articulation, etc.; partial paralysis of the œsophagus; impairment and even loss of vision; dyspnoea, especially on exertion; wandering pains, and sometimes numbness of the limbs; cardiac debility, a slow pulse, lowered temperature, irritability of the bladder, and a low specific gravity of the urine; a dark, spotted, erythematous flush of the face, intensified by alcohol or by mental excitement; a bloodshot condition, and occasionally yellowness, of the conjunctivæ; caprice of appetite, nausea, diarrhoea or constipation with pale and hard feces. The eruptions upon the skin above noticed sometimes follow the occasional use of chloral, especially in excessive doses, but more commonly result from its habitual administration. They are described as exanthematic, including scarlatiniform rashes, roseola, urticaria, and lichen, but are occasionally vesicular or slightly pustular. Sometimes they have a yellow tint. Most frequently they are confined to the face and neck, but sometimes extend to the whole body, and on the limbs are apt to be most distinct upon the surfaces of extension, on the back, and joints. They have also been observed within the mouth. They are rendered more intense by physical and mental excitement and by the use of alcohol, tea, or coffee, and are often attended by palpitation of the heart and throbbing of the arteries, and are

sometimes followed by a desquamation of the cuticle. In not a few instances injection, and even chemosis of the conjunctiva, follow the use of the drug, and may be attended with impaired vision or photophobia, due to congestion of the retinal vessels. Of the effects now enumerated many were disclosed by an inquiry set on foot by the Clinical Society of London in 1880 (*Transactions*, xiii. 117). Besides the effects which have been enumerated, there is sometimes observed a condition which denotes an altered state of the blood, such as a spongy and ulcerated state of the mucous membrane of the mouth, livid and hæmorrhagic spots upon the skin, purpurous effusions in the mucous membranes of the lungs, bowels, etc., general œdema, eczematous and scaly eruptions of the skin, alopecia, and shedding of the finger- and toe-nails. The latter effects correspond to the disorganization of the red corpuscles which is observed in some cases of acute fatal poisoning by this substance. It would seem that all such disorders assume exaggerated proportions in persons addicted to intemperance in alcohol.

Prof. Liebreich attributes a large share of these mischievous effects to the use of an impure preparation of chloral. He states that sometimes chloral, as it is sold, contains other compounds, which give rise by their decomposition to acid and irritating substances of a complex character, which have a very injurious physiological action and are liable to produce dangerous results. This eminent physician has called attention to a curious circumstance, already referred to—viz. that after a dose of chloral, alcohol produces much more than its ordinary effect in flushing the face. This seems to be due to the parietic action of chloral upon the arteries and capillaries as well as upon the heart.

When chloral was first introduced into medicine it was assumed to undergo in the blood a decomposition into formic acid and chloroform, to the latter of which its operation was ascribed, while the formic acid united with the alkalies of the blood. This view, which was purely hypothetical in its origin, has been disproved by demonstrating that chloral is not decomposed in the blood at all, and may be found in this fluid after having been taken by the mouth; that its action is the same whether the blood be normally alkaline or abnormally acid; and that in the frog its characteristic effects take place whether the circulating fluid be blood or a saline solution.

Medical Uses.—*Insomnia*: Chloral appears to be indicated when sleeplessness is dependent upon a vascularity due to exhaustion rather than to primary excitement of the brain: thus it has been found useful when loss of sleep follows severe and prolonged mental application or excitement of feeling, or accompanies the general debility following acute diseases attended with delirium or severe pain, or is associated with acute *mania*, especially of the puerperal form. The somewhat analogous condition which exists in *delirium tremens* is very amenable to this medicine, especially in the forming stage of the affection known as “the horrors,” and which so frequently follows surgical injuries in drunkards; it is useful also when great nervous excitement and restlessness are associated with extravagant phantasms. Nevertheless, its depressing effects are to be guarded against in this affection as in the different forms of *insanity*. “The tide of opinion seems to have set directly against its use, save in certain cases and under certain conditions” of the latter disease. The weight of authority is opposed to its use, partly upon the ground that it tends to suddenly depress the heart and the nervous system, and partly because it aggravates the delirium in many cases. (Compare Kane, *Med. Record*, xix. 60.) The grounds of this condemnation are distinctly and emphatically set forth by Weiss (*Centralblatt f. Therapie*, i. 119), who from a large experience shows that the medicine does more harm by its depressing than good by its hypnotic influence in all protracted maniacal seizures, and by its continued use induces a cachectic condition that prolongs, and even perpetuates, the disease. He charges it with the production of numerous lesions from decubitus (ulcers, etc.) in the paralytic and chronic insane, and, in a word, as a double-edged sword that, while it overcomes maniacal manifestations, tends to undermine the powers of life.

Although far inferior for the relief of *pain*, chloral is a very useful substitute for opium and its preparations in many cases in which the pain is of moderate intensity or when an idiosyncrasy exists which renders these medicines ineligible. Pain in nervous trunks and extremities, particularly in neuralgia, whether of central or peripheral origin, in toothache, lead-colic, cancer, and tumors compressing nerves, is more or less palliated by chloral. But its anodyne influence is very transient, and when it passes off the pain appears to be intensified. This remark applies also to the use of chloral in nervous *headache*. It has been employed with advantage in cases of *angina pectoris* unconnected with obstructive disease or degeneration of the heart; but it should be used with extreme caution, if at all, whenever, from these or other causes, the action of the heart is irregular,

feeble, or tumultuous. Chloral is very efficient during *labor* in producing those effects for which chloroform and ether are commonly employed; that is to say, for allaying fruitless and excessive pains and permitting rhythmical contractions of the uterus to occur; for promoting dilatation of the os uteri; for procuring repose for the mother during prolonged labor; and for quieting alarm and allaying nervous irritability. It should be given in doses of not less than 30 grains (Gm. 2), repeated every half hour until the desired effect is produced.

Among spasmodic affections, *tetanus*, especially of the subacute form, has proved very amenable to this remedy, administered hypodermically and also by the mouth and rectum. Statistics appear to show that the mortality under its use is rather less than under that of curare, Calabar bean, and other medicines. It is said that in the more acute and active forms of the disease its efficacy is less demonstrable, but in three acute cases out of four occurring in the Pennsylvania Hospital cure followed the use of chloral. The tetanic spasm produced by *strychnia-poisoning* is equally under its control; it seems to reduce the force and frequency of the paroxysms, but a lethal dose of strychnia cannot be combated by an adequate dose of chloral, for the latter would be equally dangerous to life. A summary may here be given of Th. Husemann's conclusions after a thorough rational and experimental investigation of this subject in animals: There is no reciprocal antagonism between chloral and strychnia. But an animal under the influence of chloral will escape the effects of five or six times the minimum lethal dose of strychnia, or even of much larger doses of the latter, so long as the proper toxic effects of the chloral are not developed. In this way, even when it does not prevent death, it may greatly delay it. In animals, and also in man, its power of saving life in strychnia-poisoning depends very much upon its ability to prevent or to moderate the spasms which, if unchecked, hasten so greatly the fatal issue by exhausting the nervous centres and lowering the temperature. (Compare Faucon, *Archives générales*, Jan. 1883, pp. 74, 153, who advises that chloral should be administered hypodermically as well as by the mouth, and even by the veins.) In some instances of *tonic spasm* its effects have been beneficial. It has been used to mitigate the fits of *epilepsy* by giving it before their regular hour of recurrence when they are periodical. It may lessen the movements in *paralysis agitans*. *Puerperal convulsions* are perhaps more amenable to the influence of chloral than any other form of spasmodic disease, although it is far from being a certain remedy. To ensure its favorable action it should be given in doses of not less than 15 or 20 grains, repeated every 15 minutes until its appropriate effects appear. Its use in *infantile convulsions* is common, but its utility is not clearly proved. In a case of *hydrophobia* the medicine was found to control the active symptoms completely, but the patient died by syncope (Gunning). A case of supposed hydrophobia, reported by Broadbent as recovering under the use of chloral, was considered by some members of the Clinical Society of London as being of a different nature (*Times and Gaz.*, March, 1883, p. 308). In *chorea* it displays a decided control over the spasmodic element of the disease, and must be regarded as a valuable adjuvant in the cure of cases depending upon definite blood-disorder, nervous shock, or reflex irritation. In some uncomplicated cases it suffices for the cure, especially if given in full doses. It appears to have been very serviceable in *laryngismus stridulus* when taken by children six months old in doses of 2 grains three times a day. It has been recommended in the form of an atomized solution of 10 grains to the ounce as a remedy for the "*winter cough*" of old persons. In *whooping cough* it is of service by mitigating the violence of the paroxysms and preventing the loss of strength occasioned by their occurrence at night. It sometimes also appears to shorten the duration of the attack. In other varieties of *cough* it is a useful palliative, but is not to be compared with opium. The paroxysms of nervous *asthma* are sometimes very favorably modified by this medicine, but it is unsuited for the continuous treatment of so chronic a disease. It is one of the best remedies for obstinate *hiccup*. There is an alleged physiological antagonism between chloral and *Calabar bean*, but it is exhibited only when the doses of the two agents are duly proportioned and the chloral is administered within a very few minutes after the bean.

A mixture of chloral and morphia has been used by Trélat to produce partial anæsthesia for surgical purposes, and either exclusively for minor operations or as preparatory to the use of chloroform in graver ones. It is contended that in this manner the dangers of the latter agent are diminished, both by the action of the morphia and by the smaller quantity of the anæsthetic required (Choquet, 1880). Equal parts of camphor and chloral form an excellent topical anodyne in *neuralgia*. A 50 per cent. solution of chloral has been applied in *diphtheria* by means of a brush at intervals of half an hour, with the

effect of loosening the false membrane. After the separation of the latter a weaker solution was applied at longer intervals, which appeared to hasten the cure. The combined deodorizing, antiseptic, and stimulant qualities of chloral have caused various applications of it, especially as a *surgical dressing*. A solution of 1 part in 100 of water has been found sufficiently strong. This is applied on lint to unhealthy surfaces, such as gangrenous, indolent, erysipelatous, diphtheritic, cancerous, mercurial, and carious *ulcers*, or as an injection for parts not so easily reached, as in cases of *dysentery*. It has been recommended internally (Curci) in acute dysentery and in *typhoid fever*, but should unequivocally be condemned, as well as in the treatment of the acute *gastro-enteritis* of children. It also corrects the fetor and lessens the discharge in *ozæna*, for which purpose a solution of 1 part in 200 to 300 may be applied by means of the nasal douche. A solution of 1 or 2 parts in 100 corrects *fetor of the feet*. Stronger solutions, containing from 20 to 40 grains of chloral to an ounce of water, have been used to prevent the decomposition of animal tissues immersed in them, which they are stated to do without injuring the color or the texture. They have also been successfully employed to inject dead bodies used for dissection. A solution of 1 part in 20 of water forms an excellent lotion in *pityriasis* of the scalp, and sometimes cures the disease if it is recent. A 10 per cent. solution of chloral injected into an *erectile tumor* has effected its cure, and a like result has followed in *varicocele*. A 1 or 2 per cent. solution has been found an efficient injection in *gonorrhœa*.

Poisoning by chloral should be treated by the same general method which is applicable to other forms of narcotism, including cold to the head and neck, the use of coffee or caffeine, galvanism applied to the diaphragm, mechanical stimulants, such as friction and flagellation, etc. Atropia and digitalis have been employed to stimulate and tonify the heart, and nitrite of amyl for an analogous purpose. Carbonate of ammonia has been injected into the veins. Strychnia has also been used as a physiological antidote to chloral. Strychnia would seem appropriate, so far as it tends to rouse the activity of the spinal cord, but it does not tend to diminish the action of chloral upon the brain. But clinical evidence leaves no doubt of the efficacy of *strychnia* in chloral-poisoning. Its first effect is to reduce the abnormal frequency of the pulse and increase its volume, while it causes the respiratory act to be fuller (Moore, *Med. News*, xli. 566; Da Costa, *Phila. Med. Times*, xiii. 421). A hypodermic injection of 2 minims of "solution of strychnia," *Br. Ph.* (gr. $\frac{1}{60}$), may be given at intervals of about half an hour. It is of the utmost importance to combat the singular coldness which the poison tends to produce by means of artificial heat, such as hot cloths, bottles, sand, etc. applied over the heart, to the spine and extremities, and by small and repeated doses of alcohol, which may be administered by the mouth or rectum or hypodermically.

Administration.—Chloral is too irritating for ordinary hypodermic use, but in strychnia-poisoning it may be so administered in the dose of from 10 to 20 grains (Gm. 0.60–1.20). This operation is apt to be followed by abscess. Its injection into the veins may be mentioned only to be condemned. By the mouth the average dose for an adult is between 10 and 30 grains (Gm. 0.60–2.00), which may be repeated at intervals of 1 or 2 hours. In convulsive disorders much larger doses may be required. For children about 1 grain (Gm. 0.05) may be prescribed for each year of the child's age. The solution should be flavored with an agreeable syrup; peppermint-water masks its taste effectually. Enemas of chloral may be prepared by dissolving from 15 to 60 grains (Gm. 1–4) of the compound in a little water, rubbing up the solution with the yolk of egg, and mixing it with a sufficient quantity of milk. Suppositories may be made as follows: Cocoa-butter, spermaceti, of each 2½ Gm.; powdered chloral, ½ Gm.; or, cocoa-butter 2 Gm.; spermaceti, powdered chloral, of each 3 Gm., for one suppository (Mayet). The ready solubility of chloral hydrate in fatty excipients has led to the preparation of the following for external use: Chloral 6 parts, almond oil 30 parts; or chloral 7 parts, lard 27 parts, white wax 3 parts; or, for a plaster, chloral 1 part, white wax 2 parts, cocoa-butter 2½ parts.

CHLORAL BUTYLICUM.—BUTYLCHLORAL HYDRATE.

Hydrate de chloral butylique, Fr.; *Butylchloralhydrat*, G.

Formula $C_4H_5Cl_3O.H_2O$. Molecular weight 193.2.

Preparation.—It is prepared by passing chlorine gas into acetic aldehyd, C_2H_4O , which should be placed in a refrigerating mixture to lessen the violence of the reaction. The apparatus is connected with a reversed condenser, which carries the condensable prod-

ucts back into the flask, while the uncondensable gases are allowed to escape. Gradually the temperature is permitted to rise, and when the hot liquid ceases to absorb the chlorine gas this part of the operation is finished. The mass is now subjected to repeated fractional distillation until a product is obtained boiling uniformly between 163° and 165° C. (325.4° and 329° F.), which is butylchloral, and by dissolving in water and crystallizing the hydrate is obtained. That portion of the crude product distilling at a lower temperature requires treatment with sulphuric acid to decompose the hydrate contained in it, and subsequent fractional distillation.

Properties.—Butylchloral is a colorless oil heavier than water, of a peculiar odor somewhat like that of ordinary chloral. The hydrate crystallizes from water in thin white scales of a silky lustre, a peculiar somewhat fruit-like odor, a warm bitterish taste, and a neutral reaction. It melts at 78° C. (172.4° F.) to a colorless clear liquid, and at a higher heat vaporizes without leaving any residue. It is freely soluble in alcohol and ether, from which it crystallizes unaltered, is soluble in cold water with difficulty, freely soluble in glycerin and hot water, and volatilizes with the vapors of boiling water. By soda and other alkalies it undergoes decomposition in a manner analogous to the official chloral under the same conditions, yielding *bichlorallylene*, $\text{C}_3\text{H}_2\text{Cl}_2$, formate and chloride of sodium. The alcoholic solution of butylchloral acidulated with nitric acid does not yield a precipitate with nitrate of silver. Its solutions gradually undergo decomposition, and should therefore not be kept on hand except for a short time.

Composition.—When Krämer and Pinner first obtained this body (1870) they considered it to be *crotonchloral*, $\text{C}_4\text{H}_5\text{Cl}_3\text{O}$, but have since (1875) ascertained that it is *trichlorobutylaldehyd*, which is butylaldehyd, $\text{C}_4\text{H}_8\text{O}$, with 3H replaced by 3Cl. The hydrate contains a little over 9 per cent. of water.

Physiological Action.—*On Animals:* Administered to animals, it produces a tendency to drowsiness, which is, however, usually preceded by some degree of excitement, and then motility and sensibility become successively impaired, beginning at the head and gradually extending to the rest of the body. Under its full operation anæsthetic sleep occurs, with muscular resolution, during which the respiratory movements and the pulse become less ample and the temperature of the body falls, it may be as much as from 1° to 3° C. Small doses increase, but large doses diminish, the respiration-rate; the pulse-rate only declines when the respiration falls greatly below its norm. Thus, if a dose of 12 grains (Gm. 0.75) be given, the pulse falls to one-half, and the respiration to one-fourth, of its normal rate. If the dose is mortal, it destroys life by arresting the action first of the lungs, and then of the heart. After death there is found vascular congestion of the meninges of the brain, and in a less degree of the membranes of the spinal cord. Intra-venous injections of this substance are said to be peculiarly adapted to prepare animals for vivisection: “the most delicate and difficult dissections may then be made without awakening either sensibility or reflex movements.”

On Man: In the dose of from 10 to 30 grains it occasions, in the course of from 5 to 10 minutes, a sense of heaviness, confusion of ideas, and dulness of the senses; cutaneous sensibility is blunted, in the face first, and afterward in the limbs, motility being at the same time more or less impaired. In from 10 to 30 minutes sleep sets in; it is deep and tranquil, and while it lasts neither respiration, circulation, temperature, nor muscular tone is greatly affected. On the return of consciousness some dulness or lightness of the head may be experienced, but it soon passes off. The most striking peculiarity of these symptoms is the conservation of muscular tone. It was pointed out by Liebreich in his original communication respecting “croton-chloral hydrate.” He described two maniacs to whom it was administered as “remaining quietly sitting on their chairs in a deep sleep for 2 whole hours together.” In medicinal doses it does not appear to derange the stomach, but its acrid taste, which persists in the throat, may excite nausea, and even vomiting. Very large doses may cause both vomiting and diarrhoea, and the former effect has been induced by the hypodermic administration of the medicine.

The question as to the *modus operandi* of this preparation has been variously explained by different investigators. Some will have it that in the blood it is resolved into chloroform and formic acid, of which the former is the real cause of the characteristic phenomena. But since these phenomena, and especially the conservation of muscular tonicities, are not produced by chloroform, the theory may be discarded as inadequate. It is not worth while to pursue such investigations, which are as vain as those which have arisen respecting the soporific effect of opium, and which the satirist has answered as intelligibly as the scientist by referring them to a “vis dormitiva.”

Medical Uses.—Butylchloral is anodyne or anæsthetic rather than narcotic. The

indications for its employment were originally stated to be: 1, its substitution for chloral hydrate in cases of heart disease; 2, in neuralgia of the trigemini; 3, when very large doses of hydrate of chloral are necessary to produce sleep. In the last case it was recommended to associate the two hypnotics. Experience has proved that it is of little use even in *neuralgia* unless the pain affect the fifth pair. In that form of the disease, however, it is a most useful anodyne. If doses of from 5 to 20 grains (Gm. 0.30–1.30) are given at intervals of 15 or 30 minutes, the pain is apt to be palliated even before sleep is induced. In this manner it has proved very efficient in cases of *painful spasm* (tic douloureux) of the face. In ordinary facial neuralgia occurring in young persons, especially in anæmic women and girls, it is peculiarly efficient. It is also serviceable in *nerveous headache*, and is a palliative of *dysmenorrhœa*. In some cases of *insomnia*—such, for instance, as are frequent in chronic phthisis—a dose at bedtime of from 5 to 15 grains (Gm. 0.30–1.0) is useful, but its primary effect is not maintained, and larger doses become necessary. Butylchloral is contraindicated by hyperæmia of the brain, by an irritable condition of the gastro-intestinal mucous membrane, and by diseases which impair the vigor of the heart.

It may be given as a soporific in doses of from 3 to 10 grains (Gm. 0.20–0.60), but the smaller dose is preferable, and may be repeated at intervals of an hour or less until the due effect is obtained. Females are much more readily than men affected by small doses. Much larger doses have been recommended, as from 8 to 15 grains, and even from 30 to 60 grains (Gm. 0.40–1.00, 2.00–4.00); but they can rarely be necessary or safe. The extreme bitterness of the medicine requires it to be administered in a solution capable of masking its taste, such as glycerin and syrup flavored with essence of peppermint, or, still better, in syrup of liquorice-root. It may also be given in a mixture of the following description: butylchloral hydrate 5 to 10 parts; glycerin 20 parts; distilled water 130 parts; the mixture to be shaken before it is used. The dose of this preparation is half an ounce, followed in 5 minutes by a second, and in 10 minutes by a third. It is well to begin with a small dose, so as to avoid hypnotism, when the anæsthetic effect alone is desired; but to produce sleep, from 15 to 45 grains (Gm. 1–3), according to the patient's constitution, may be given at bedtime. As a topical application for the relief of neuralgia a mixture of equal parts of butylchloral and tincture of camphor may be applied. Its hypodermic use is not to be recommended, on account of the abscesses it occasions. If poisonous effects result from an overdose, it is advised to combat them with artificial respiration and electricity along the spine and at the superficial portion of the pneumogastric nerves, while stimulants are applied to the extremities.

CHLOROFORMUM VENALE, U. S.—COMMERCIAL CHLOROFORM.

Chloroforme vénéral, Fr.; *Küpfliches Chloroform*, G.

CHLOROFORMUM PURIFICATUM, U. S.—PURIFIED CHLOROFORM.

Chloroformum, Br.; *Chloroformium*, P. G.; *Formylum trichloratum*.—*Chloroforme pur*, Fr.; *Reines Chloroform*, G.

Formula CHCl_3 . Molecular weight 119.2.

Origin and Preparation.—Chloral is formed from alcohol and chlorine, and, on decomposing chloral by an alkali, chloroform and a formate of the alkali are produced; the conditions for these two reactions are present on bringing together alcohol and chlorinated lime, the chlorine of which converts the former into chloral, which is at once decomposed by the calcium hydrate, yielding chloroform and calcium formate, Ca_2CHO_2 (see CHLORAL). Calcium formate is, however, not found in the residue of the distillation, but is decomposed by another portion of the chlorinated lime into calcium carbonate and chloride and water. Omitting all intermediate reactions, and using for chlorinated lime the formula of Odling or of Stahlschmidt (see page 361), the final result is expressed by the equations:

The theoretical quantity of chloroform obtainable according to the first of these equations would be 33.6 per cent., according to the second 30.6 per cent., of the weight of available chlorine contained in the chlorinated lime; by working on the large scale the yield of chloroform ranges between 22 and 24 per cent.

To prepare chloroform, 6 parts of the assayed chlorinated lime are mixed with about 24 parts of water, and the mixture strained into a still; 1 part of stronger alcohol is added, and the whole heated to 40°C . (122°F .). With the further application of very little heat the reaction now proceeds rapidly, the temperature rises, and the chloroform, mixed with some alcohol, distils over. The distillate is washed with water; the subsiding layer constitutes *crude chloroform*. The washings are preserved and employed in a subsequent operation. (For papers on the manufacture of chloroform consult *Amer. Jour. Phar.*, 1862, pp. 25, 42; and 1868, p. 289.)

The British Pharmacopœia gives a process for preparing chloroform in which less water (18 parts for the above quantities) is used, and slaked lime is put into the still with the chlorinated lime—an addition which has been recommended by Siemerling, Larocque, and others, but seems superfluous; otherwise, the process scarcely differs from the one given, except that the water is mixed with the alcohol and the solid ingredients are mixed with the liquid in the still.

Thus prepared, crude chloroform varies in specific gravity between 1.45 and 1.49, and imparts to strong sulphuric acid, after having been agitated with it, a brownish or brown color, the degree of coloration depending upon the amount of impurities present.

Chloroform may likewise be prepared by distilling wood-spirit (methyl alcohol) or acetate of calcium with chlorinated lime. Chautart proposed to prepare chloroform from oil of turpentine, but Soubeiran proved that chlorinated lime diffused in water acts violently upon the oil, and that but little chloroform having a turpentine odor is obtained. Damoiseau (1881) thinks that pure chloroform may be advantageously prepared by passing a mixture of methyl chloride, CH_3Cl , and chlorine in proper proportion through a long tube containing animal charcoal and heated to between 250° and 350°C . (482° and 662°F .).

Purification.—Commercial chloroform 200 parts (100 oz. av.); sulphuric acid 40 parts (20 oz. av.); carbonate of sodium 10 parts (5 oz. av.); lime, in coarse powder, 1 part ($\frac{1}{2}$ oz. av.); alcohol 2 parts (1 oz. av. = $9\frac{3}{4}$ fluidrachms); water 20 parts (10 oz. av. = $9\frac{3}{8}$ fluidounces). Add the acid to the chloroform, and shake them together occasionally during 24 hours. Separate the lighter liquid, and add to it the carbonate of sodium previously dissolved in the water; agitate the mixture thoroughly for half an hour and set it aside; then separate the chloroform from the supernatant layer, and mix it with the alcohol. (When the mixture has separated into two transparent layers.—*U. S.* 1870), transfer the chloroform to a dry retort, add the lime, and, taking care that the temperature in the retort does not rise above 67.2°C . (153°F .), distil, by means of a water-bath, into a well-cooled receiver until the residue in the retort is reduced to 2 parts (1 oz. av.). Keep the product in glass-stoppered bottles, in a dark place.—*U. S.*

The process is identical with that of the *U. S. P.* 1870, except that the alcohol has been slightly reduced, and that the sentence above enclosed in brackets, has been omitted. The process of the British Pharmacopœia is essentially the same, but it directs the agitation of the crude chloroform for 5 minutes with an equal volume of sulphuric acid, and omits the addition of the alcohol directed in the above formula, thus obtaining a somewhat heavier product. On agitating crude chloroform with strong sulphuric acid the impurities contained in the former are destroyed, the chloroform separating as a colorless layer upon the acid. It may now be at once transferred to a retort containing some chloride of calcium and lime, or preferably is deprived of the adherent acid by washing with a solution of sodium carbonate. The clear chloroform now obtained will, on the addition of the alcohol, again become slightly turbid from the separation of water; this water should be removed by allowing the mixture to rest for a short time, as directed in the *U. S. P.* 1870, or the mixture should be well agitated and left in contact with the lime for some time before distillation is commenced; the whole of the distillate will then be transparent. If the distillation is now effected at a temperature not exceeding 67.2°C . (153°F .), with the precaution of leaving a small quantity of liquid in the still, all impurities will be effectually separated which may have escaped the action of the acid, because they have a higher boiling-point than chloroform.

Properties.—Commercial chloroform, *U. S. P.*, should contain at least 98 per cent. of chloroform, should have a density not less than 1.470, and otherwise should have the sensible properties of the following:

Purified chloroform is a limpid, colorless, diffusive liquid, not inflammable, of an agreeable ethereal odor, a hot saccharine taste, and of a neutral reaction. It is soluble in about 200 parts of water, to which it imparts its taste, and in all proportions in alcohol

and ether; also in benzol, benzin, and fixed or volatile oils. Sp. gr. 1.485–1.490 at 15° C. (59° F.). It boils in a dry flask at 60° to 61° C. (140° to 142° F.), corresponding to the presence of $\frac{1}{4}$ to 1 per cent. of alcohol. It is a solvent for paraffin, gutta-percha, caoutchouc, many resins, most alkaloids, iodine, bromine, etc.

Pure (absolute) chloroform has at 15° C. (59° F.) the density 1.499 (Hirsch), is very prone to change when in contact with air and diffused light; it keeps, however, entirely unaltered in direct sunlight if the air has been completely expelled from the vessel. Chloroform reduced by the addition of alcohol to 1.49 is readily decomposed by direct sunlight, more slowly when exposed to diffused daylight. If reduced to the density 1.480–1.484, it remains unaltered in diffused light for years, and for 10 hours in direct sunlight, provided all moisture has been excluded; in the presence of some water decomposition gradually commences. Chloroform below the density 1.475 is not affected by light. This behavior explains the necessity of keeping chloroform of 1.49 protected from the light, which is not required if the density is lowered to about 1.48 by the addition of $1\frac{1}{2}$ per cent. of alcohol. The products of decomposition have the suffocating odor of *phosgene gas*, COCl_2 , redden and often bleach moistened blue litmus, and liberate iodine from potassium iodide; even an incipient decomposition is detected by evaporating spontaneously a drachm of chloroform with a drop of a neutral solution of litmus, which will thereby acquire a red color.

Partially-decomposed chloroform may be restored to its original purity by agitating it with solution of sodium carbonate and rectifying it afterward over a little lime. Previous treatment with strong sulphuric acid will be necessary only when it becomes colored on being agitated with the chloroform.

When chloroform is shaken in a perfectly clean glass-stoppered vial with an equal bulk of sulphuric acid, no color should be imparted to either liquid after remaining in contact for 24 hours. Should a coloration appear, the chloroform must be regarded as unfit for inhalation, and should be purified by the official formula. When it is agitated with an aqueous solution of nitrate of silver a white precipitate of chloride of silver is not produced.

Tests.—The purity of chloroform is ascertained by its complete volatility, its neutral reaction, its behavior to concentrated sulphuric acid, nitrate of silver, and iodide of potassium, and by its physical properties.

“If 1 Cem. of *commercial chloroform* be agitated with 20 Cem. of distilled water, the latter, when separated, should not render test solution of nitrate of silver more than slightly turbid (limit of foreign chlorine compounds). When shaken with an equal volume of sulphuric acid the subsiding acid layer should not become quite black within 24 hours. A portion evaporated should leave no fixed residue. If 5 Cem. of *purified chloroform* be thoroughly agitated with 10 Cem. of distilled water, the latter, when separated, should not affect blue litmus-paper (absence of acids) nor test solution of nitrate of silver (chloride) nor test solution of iodide of potassium (free chlorine). If a portion be digested, warm, with solution of potassa, the latter should not become dark-colored (absence of aldehyd). On shaking 10 Cem. of the chloroform with 5 Cem. of sulphuric acid in a glass-stoppered bottle, and allowing them to remain in contact for 24 hours, no color should be imparted to either liquid. If a few Cem. be permitted to evaporate from blotting-paper, no foreign odor should be perceptible after the odor of chloroform ceases to be recognized.”—*U. S.*

Detection of Chloroform.—Chloroform has sometimes been used for the adulteration of volatile oils; in these and in other liquids it may be detected by distilling them with a little alcohol at a temperature of about 65° C. (149° F.). Hager (1868) recommended the treatment of this distillate with zinc and sulphuric acid, when the chloroform will be decomposed and hydrochloric acid recognized in the liquid by nitrate of silver. Lustgarten (1882) suggested as a reliable test the transient blue-green color which is produced on warming chloroform with naphthol and soda solution. A. W. Hofmann (1870) recommended the addition of the alcoholic liquid to a mixture of anilin and alcoholic solution of soda and warming, when the characteristic odor of isonitrites will be developed; 1 part of chloroform in 5000 to 6000 parts of alcohol may thus be detected, and it may be readily distinguished from *chloroethylidene*, which closely resembles chloroform in physical properties. All compounds, however, which on treatment with an alkali produce chloroform, iodoform, or bromoform give the same reaction.

Pharmaceutical Uses.—Chloroform is used as a solvent in the preparation of atropine and other alkaloids.

CHLORAMYL, recommended by Dr. Sanford (1879), is a mixture of chloroform 1 pound

and amyl nitrite 2 drachms. There being a chloride and several chlorine substitution-products of amyl, the name does not appear to be a proper one.

LIQUOR CHLOROFORMI COMPOSITUS. Some years ago a nostrum was introduced under the name of *chlorodine* (or *chlorodyne*), and subsequently several formulas were published, differing, however, considerably in their composition. The following formula has been devised by Prof. Remington, and is based upon that given by C. Bullock (1865), the chief difference being the substitution of alcohol for molasses: Dissolve 16 grains of hydrochlorate of morphia in 1 drachm of water and 1 fluidounce of alcohol; add to this chloroform 3 fluidrachms; tincture of *Cannabis indica* 2 fluidrachms; tincture of capsicum 18 minims; oil of peppermint 4 minims; dilute hydrocyanic acid 24 minims; and perchloric (or hydrochloric) acid $\frac{1}{2}$ fluidrachm. Each fluidrachm contains 1 grain of morphia.

Physiological Action.—*On Animals:* In animals whose power of cutaneous absorption is very great, such as frogs and snails, the effects of chloroform are very prompt, decided, and prolonged. The last peculiarity is due to the slowness of their pulmonary exhalation. Of warm-blooded animals, birds are the most susceptible, and cats, rabbits, and rats are more so than dogs. In general, great facility in coming under the influence of the vapor implies a tendency to recover rapidly from its effects. These effects vary for the same animal and for man according to the amount of the vapor inhaled in a given time. Some experimenters have maintained that the blood in the arteries becomes dark during chloroform anæsthesia, while others declare that it acquires a lighter hue. In truth, the color varies according to the freedom of the respiratory act. If the vapor is slowly introduced into the lungs, so as to produce its effects gradually, there is no tendency to darkening of the arterial blood; but a rapid and excessive use of chloroform induces a dusky color of the integuments, by occasioning a degree of asphyxia, which is the more readily produced in consequence of the simultaneous insensibility of the nervous centres. Immediately on suspending the inhalation the natural color returns to the arterial blood, and even the venous blood for a time is less dark than natural. During the first stage of chloroform inhalation nervous symptoms are apt to be developed, and sometimes spasms and convulsions, which are ascribed, not to the action of the absorbed vapor upon the nervous centres, but to the reflex irritation by that vapor of the branches of the superior laryngeal and pneumogastric nerves, which also interferes with the action of the heart and of the lungs. Hence the inhalation of chloroform vapor in large quantities acts by cutting off the supply of atmospheric air; by irritating the respiratory passages and thereby occasioning spasm of their walls, as well as reflex spasm of other muscles; and finally by absorption into the blood.

The experiments of Bernard led him to the conclusion that all general anæsthesia is central in its source; that is to say, is due to the direct action of the anæsthetic upon the spinal cord alone or upon the brain alone, or upon both at once, and that from these centres it controls the sensibility of the distal extremities of the nerves. If the brain alone receives the direct influence of chloroform, the sensibility of the spinal marrow and of the nerves is not impaired; if the agent is limited in its operation to the spinal cord, it does not affect the brain, but it deprives the nerves of sensibility; and finally, if applied only to the extremities of the nerves, its influence is not propagated to the nervous centres. 1 grain of chloroform injected hypodermically into a rabbit is said to cause an anæsthetic sleep of several hours' duration. The experiments of Brown-Séquard prove that chloroform may act in a different manner. Applied rapidly on the shoulder of a guinea-pig, it at first excited reflex contractions of the subjacent muscles, but in a short time the respiration diminished, the temperature declined, and the animal staggered, and fell into a state of insensibility which lasted for several hours. These effects may be regarded as inhibitory phenomena (*Times and Gazette*, Nov. 1880, p. 627).

The vascular condition of the nervous centres during chloroform inhalation differs at the different stages of that process. So long as the agitation lasts which usually precedes complete anæsthesia the cerebral blood-vessels are congested, and the brain will project through an aperture made in the cranium of the animal experimented upon, but with the approach of the full anæsthetic state this congestion subsides, the swollen convolutions shrink, and the excessive vascularity is replaced by unusual pallor of the tissues. In this particular the sleep produced by chloroform (and by ether) is identical with natural sleep, in which also there is a diminished vascularity of the brain. Compression of the carotids in like manner, by lessening the amount of blood, and therefore

the tissue-changes in the brain, induces first of all diminished sensibility in the brain, and then loss of consciousness. The first or congestive stage of chloroform-anæsthesia resembles that of the sleep produced by alcoholic intoxication and by excessive doses of opium; it is stupor or coma rather than sleep. Although the brain during the full anæsthesia of chloroform is anæmic, it does not follow that this condition suffices to explain the loss of general sensibility: for not only is the loss far greater than is ever observed in natural sleep, but the local application of chloroform occasions a partial anæsthesia, and there are surgical cases in which the perception of touch and of pain has been completely lost, although consciousness, a cerebral function, remained quite unimpaired. These cases are exceptional, but they seem to show that in chloroform-anæsthesia there must be a change produced in the conducting channels of sensibility as well as in the central perceptive organ which recognizes the existence of pain. Ringer has shown (*Practitioner*, xxvi. 437, 1881), as Mommsen had already done (*Virehow's Archiv*, lxxxiii. 273), that chloroform arrests the frog's heart in diastole; but the former also observed that if, before the arrest becomes complete, ammonia be applied, the pulsations may be renewed and the life of the animal saved. Vulpian too has called attention to the double action of chloroform on the respiratory centres as well as on the motor ganglia of the heart, and the greater danger to life involved in the latter action. The committee on anæsthetics of the British Association (1879) found that chloroform may cause death in dogs by primarily paralyzing either the heart or the respiratory organs, and that its action on the former is sometimes unexpected, and apparently capricious, as it is found to be in surgical operations performed with chloroform.

The order in which the several organs are successively affected is generally this: first, the brain, the organ of consciousness, is benumbed, and simultaneously voluntary motion is impaired, while reflex motility may be momentarily increased in the voluntary muscles and persist in the muscles of organic life; finally, the first-named muscles undergo complete relaxation, and the only remaining signs of life are given by the lungs and the heart.

In regard to the nature of the action by which chloroform impairs or destroys for a time sensibility little more than conjecture can be advanced. According to Bernard, it consists in a partial and temporary coagulation of the contents of the nerve-cells—a view which he derived from the action produced in living muscle by injecting its blood-vessels with chloroform or by suspending it in the vapor of this liquid. In the animal thus treated the muscle gradually returns to its normal condition. Similar effects are produced by a like treatment of the nerve-trunks themselves. It is suggested that this partial and temporary hardening of the nerve-tissue suspends the functions of the nerve, and that some analogical reason for adopting it as an explanation may be found in the fact that Infusoria lose all signs of life when dry, and regain them on being moistened; and in the case also of a frog to which salt has been administered, and which so abstracts the circulating fluids of the animal as to reduce it to a state of apparent death, in which, among other things, the crystalline lens grows opaque. The rapid, not to say instantaneous, return of a chloroformed animal to its normal state does not appear to harmonize with this theory.

In the view of Bernard, that anæsthesia is due to anæmia of the nervous centres, may be found the most plausible theory of chloroform-narcosis, but it is by no means in harmony with the observations which go to demonstrate that the entire vascular system is paralyzed and all the blood-vessels in the body dilated. This paralysis and consequent dilatation of the blood-vessels are invoked by Schiff to explain the suspension of the heart's action, which, according to him, is due, not to an inhibitory influence of the chloroform directly operating through the nervous system, but to the fact that the increased capacity of the vascular system withdraws from the heart the blood which is the normal and necessary excitor of its movements. It is argued that this view is sustained by the effects which, under the circumstances, are produced by ligatures upon the limbs, by means of which the blood is retained in the trunk and the heart is duly supplied. But it should not be overlooked that this expedient not only restores a due amount of blood to the heart, but also to the brain, and that to the latter influence may be attributed the recovery from apparent death which has been observed in several instances, in man as well as in animals, when they have been so placed that the blood in the trunk gravitated toward the head.

On Man: Chloroform is an irritant, producing redness of the skin when topically applied, and even vesication if its evaporation is prevented. When from 10 to 20 minims of pure chloroform are injected subcutaneously, very considerable pain is experienced, which,

however, presently subsides, and is succeeded by a feeling of numbness and by anæsthesia of the adjacent parts; a puffy swelling forms at the seat of the injection, and an induration which remains for several days. The numbness may continue even for a week or more, and in the case of the leg may affect all the region to which the nerve is distributed near which the injection was made (Bartholow). Other observers have noted the persistent induration following the puncture, and have also described gangrene as an effect of it, but they have not spoken of the numbness just referred to. The local phenomena of swelling and inflammation appear to have been due to an imperfect manipulation of the syringe; indeed, one reporter (Féréal) declares that the operation causes no more pain than if water instead of chloroform were injected. The soporific action of chloroform used in this manner comes on slowly, but is curiously prolonged. At least 4 Gm., and sometimes more, of chloroform are necessary to cause sleep even at the end of several hours; it is not accompanied by anæsthesia, the least disturbance sufficing to arouse the patient, but it may last for 6 or 7 hours. The temperature is reduced by 1° or 2° C., and the pulse by perhaps ten beats. The tardy and feeble sleep can only be explained by the very gradual absorption of the chloroform into the blood. A large number of cases of poisoning by chloroform taken into the stomach are recorded (*Am. Jour. of Med. Sci.*, July, 1881, p. 277). In one of recovery a weakly man had swallowed 3 ounces of chloroform (*Practitioner*, xxx. 47). Doses of half an ounce or more produce general convulsions, insensibility, dilated pupils, trismus, foaming at the mouth, slow and stertorous respiration, and lividity of the face. The pulse is feeble, and sometimes irregular. The stools may be bloody and blood may be vomited. Death may result from pulmonary asphyxia alone, or from this together with gastritis. After death the brain is found greatly congested, and the mucous membrane of the air-passages and of the alimentary canal are in a similar condition. The bronchia are filled with mucus tinged with blood or mixed with pus. The blood in the vessels is fluid. A similar condition of the bronchia has been met with in persons who died with suffocative symptoms 1 or 2 days after inhaling chloroform, especially in the old and obese (Riche).

The vapor of chloroform when inhaled slowly is apt to produce excitement, usually of an agreeable sort, with extravagant gaiety and gesticulation. In fuller anæsthetic doses it occasions a sense of warmth and stimulation, radiating from the chest to the extremities, followed by whirring noises in the ears and a sense of numbness throughout the body, soon followed by a complete loss of consciousness. Sometimes consciousness is more or less preserved, while the sense of touch and that of pain are abolished. But, as a rule, sensibility is first suspended, then perception, and finally motility. Sensibility to pain is lost before the sense of temperature or tactile sensibility is greatly impaired. During the full anæsthetic sleep the respiration is at first soporose and quickened, but soon becomes tranquil and slow; the pupil presents all degrees of dilatation; the pulse is at first fuller and more frequent, but subsequently nearly normal; the voluntary muscles are relaxed, but sometimes rigid or even cataleptic; and in females hysterical phenomena occasionally appear.

The question has been raised whether a person could be chloroformed during sleep, the numerous alleged instances of its having been done with criminal intent being naturally open to doubt, and even to suspicion. It is certain that on various occasions the experiment has been tried with the result of awaking the sleepers (Girdner, *Med. Record*, xxiv. 454), but it is equally certain that when conducted with due precautions it has been successful, especially with children. In a girl eight years old an abscess was opened under such circumstances by Curtis in 1873 (*Med. Record*, xxiii. 595). Schauffler (*Kansas City Med. Jour.*, June, 1875, p. 106) removed a pebble from the nostrils of a child that he had chloroformed while sleeping. The experiments of Cerceuil in France, although for the most part negative, were in several instances affirmative (*Ohio Med. Recorder*, Jan. 1877, p. 337), and the editor of the journal just referred to says: "Of three attempts at chloroforming during natural sleep of which we were personally cognizant, two were successful." Dr. Quinby also not only accomplished it upon a person forewarned of the intention, but also upon two lads, on one of whom he performed evulsion of the toe-nail, and in the other case opened an abscess in the mouth and extracted several teeth. In both of the latter cases the anæsthetic was administered during the first sleep at night, and neither patient awoke until the usual hour the next morning (*Trans. Amer. Med. Assoc.*, 1880, xxxi. 519). Halderman reports two successful cases as well as several failures (*Med. Record*, xxiii. 594), and Neilson a complete chloroform narcosis obtained during sleep in a boy of ten years, during which the operation of circumcision was performed (*ibid.*, p. 595). (For addi-

tional illustrations see *Boston Med. and Surg. Jour.*, June, 1883, p. 595, and *Med. Record*, xxiv. 23, 613.)

The advantages of chloroform over other anæsthetics consist in its agreeable odor, the small quantity of it required, its non-inflammability, and the rapidity and completeness of its effects. Its one disadvantage is that it often destroys life. The number of deaths caused directly and exclusively by the administration of chloroform, independently of any error in the mode of its inhalation or in the quality of the agent or any unfitness of the patient, may now be counted by hundreds. A large proportion of them took place during operations which under other circumstances are considered trifling. It seems probable that many of these operations, such as that for strabismus, the extraction of teeth, the opening of abscesses, etc., were performed while the patient was in a sitting posture, and therefore most exposed to the dangers of syncope, which it has been shown is the chief cause of death in chloroform inhalation. No other solution is so plausible of the otherwise singular fact that the danger of chloroform is in an inverse proportion to the severity of the operation performed. Again, the almost complete safety of chloroform inhalation during natural labor lends itself to a similar explanation. The gravid uterus restricts the circulation of the blood in the lower limbs and increases it in the upper portion of the body, and this condition is mechanically exaggerated by the throes of labor, as well as by the mental excitement of the parturient female. On the other hand, in the state of exhaustion and terror which accompanies most of the serious accidents of labor and of operative obstetrics the conditions of safety are reversed, and chloroform becomes peculiarly dangerous. It is maintained by some of those who admit the dangers of chloroform that they do not exist when this agent is employed in operations upon children. It is alleged that their immunity is owing to the absence of that dread of the possible consequences of the inhalation which older persons experience, and to the much greater rapidity with which they fall into the anæsthetic condition. These reasons may be valid in favor of using a safe anæsthetic in operations upon infants and children, but they do not appear to be sufficient to warrant the selection of chloroform for this purpose. It may be stated that the preference given to chloroform over other anæsthetics by European surgeons has been sensibly modified since the death of its introducer, Sir James Y. Simpson, and that professional opinion tends to the point occupied by Schiff, who "considers that chloroform should be banished from practice as an anæsthetic agent, except in cases in which extraordinary resistance to the action of ether shows itself, in which instances it might be allowed to mix a little chloroform with it in order to produce the commencement of anæsthesia, which should afterward be continued with pure ether." Long ago (1858) Snow declared, "I believe that ether is altogether incapable of causing the sudden death by paralysis of the heart which has caused the accidents which have happened during the administration of chloroform;" and Perrin, one of the most earnest advocates of the latter anæsthetic, admits that its dangers are "the result of an accident arising most frequently during an incomplete or untimely administration of it." In 1872, Dr. Thomas Jones, who was for eleven years administrator of anæsthetics in St. George's Hospital, London, wrote: "I have administered chloroform in more than six thousand cases." . . . "I confess experience has taught me that chloroform, even when most carefully administered, is more dangerous than is generally supposed. If I was unfortunately compelled to take an anæsthetic, nothing would induce me to take chloroform." In 1880, Mr. Osborn, chloroformist to St. Thomas's Hospital, stated, in his report on anæsthetics, "Ether is given in all possible cases because of its undoubted greater safety." And in 1881 it was declared that "there have been *reported* an average of about a death [from chloroform] for every month since the time of its introduction" (Reichert). Citations like these might be multiplied to show that in England and Ireland and on the continent of Europe the use of chloroform as an anæsthetic in surgery is much less general than it was formerly. The deaths directly due to its use—occurring, with one exception, in London alone, and published in the *Medical Times and Gazette* during the four years from 1875 to 1878—amounted to fifteen, and in every case but one the mode of death was by syncope. Such deplorable results ought certainly to be considered seriously by surgeons before they add to the ordinary and inevitable risks of an operation one which no sagacity can foreknow and no skill prevent.

When chloroform is repeatedly used, or employed, as it frequently is, to produce intoxication, it occasions cerebral disorders resembling those caused by alcohol and by morphia. According to Svetlin, this occurs in two forms, of which the most usual may continue indefinitely, as hypochondriasis, melancholy, irritability, moral depravity, the delirium of persecution, or intellectual decay. More rarely the symptoms are acute, lasting for

about a week, and characterized by violent delirium, maniacal fury, and hallucinations of sight or hearing. Similar effects have been produced by chloral (*Archives gén.*, Juill. 1883, p. 96). The chloroform habit is as inveterate as the opium habit, and far more pernicious.

Uses.—What has been said above indicates the limits of the uses of chloroform in surgery which, in our judgment, experience has established. If the patient is robust and not exhausted, if the anæsthetic is administered to him in a recumbent position, and if its action is restrained within the limits of complete narcotism, its dangers are diminished, but they are not removed, and they cannot always be foreseen.

During pregnancy chloroform has been given with advantage, both by the stomach and by inhalation, to arrest obstinate vomiting, but its tendency to relax the mouth of the uterus should restrict its use to cases in which other remedies have failed, and also to the production of the first stage of narcotism only. During labor chloroform is indicated by the presence or the imminence of convulsions, by excessive sensitiveness of the maternal soft parts, by irregular and inefficient pains, and by the necessity of manual or instrumental interference. In all operations for the success of which the contraction of the uterus is essential the full anæsthetic action of chloroform is unsafe. Chloroform is contraindicated during labor by great relaxation of the uterus, with a tendency to flooding, and when there is persistent vomiting or acute or chronic disease of the lungs or heart, and especially degenerative changes in the latter. It is worthy of notice that in France chloroform-anæsthesia is far from being accepted by obstetricians, the two professors of obstetrics of the Medical Faculty of Paris, among others, having warmly opposed it (1878). As regards its use for palliating the ordinary pains of labor, its action ought not to go beyond the production of the first, or analgesic, stage, not only because it is sufficient, but also because in the stage of complete anæsthesia the contractile power of the uterus is very apt to be suspended.

Various spasmodic diseases have been favorably influenced by chloroform inhalation. Of these, spasmodic asthma is very speedily relieved, but the habit of using the medicine soon lessens its influence. Tetanus, traumatic as well as idiopathic, has been cured by it in many instances, and in the tetanoid spasms produced by strychnia-poisoning its influence is salutary and has often saved life. It has been used beneficially in chorea by subjecting the patient to its moderate operation for an hour or two every day, but in this disease its virtues do not counterbalance its dangers.

In puerperal convulsions the advantages of chloroform are very decided. Its inhalation should be commenced as soon as the indications of an impending paroxysm appear, such as restlessness, rigidity of the muscles, a staring expression, etc. Infantile convulsions, excited by a reflex irritation proceeding from the teeth, the digestive apparatus, etc., may be promptly allayed by chloroform inhalation, and its use for this purpose does not appear to have been injurious. All pains due to spasm are readily relieved by it, as in painter's and other forms of colic, including biliary and nephritic, dysmenorrhœa, spasms of the bladder, rectum, etc.

It affords prompt relief in paroxysms of angina pectoris, but when this affliction is associated with heart disease chloroform vapor must be very circumspectly employed.

As a local anodyne the applications of chloroform are as numerous as the seats and varieties of pain. It is very efficient in ointments or liniments made with lard, vaseline, or camphorated oil, or used hypodermically. It may also be applied as an atomized vapor on wads of cotton at the bottom of a cupping-glass or wine-glass, etc. As a topical anodyne and revulsive, chloroform with aconite is particularly useful in neuralgia when applied over the neuralgic points upon compresses protected by an impermeable covering. In 1873, Dr. Bartholow published three cases of tic douloureux, two of which were alleviated by the deep injection of chloroform, and not temporarily, but for weeks or months. In 1874, Dr. Mattison reported a case with a like issue; in 1877, Dr. Doe related a case of intercostal neuralgia accompanying herpes zoster which was relieved by the same method; and Dr. Stedman treated eight cases of different forms of neuralgia and produced a suspension or a marked mitigation of the paroxysms. These cases, all of which occurred in the United States, appear to have suggested a trial of the method in Europe, where it seems to have been first used in Switzerland by Cérenville, and afterward by Besnier in Paris. The latter judged it to be no less efficient than hypodermic morphia as an anodyne. Dujardin-Beaumetz (1879), on the other hand, concluded that it is not comparable to morphia as a local anodyne in cancer; that, moreover, nervous patients and those addicted to alcohol experience no general impression from it; and, finally, that in unskilled hands it is apt to cause serious local mischief. Cotton saturated with a solution of camphor in chloroform is one of the

best applications for the pain of an *aching hollow tooth*, and rheumatic *toothache* is palliated by bathing the gum with chloroform. Among the many affections for which chloroform is topically useful are *headache*, *rheumatism*, *dysmenorrhœa*, *painful parturition*, *swelled testicle*, the use of the *moxa* and the *cantery*, *painful hæmorrhoids*, etc. In the case of a woman affected with an accumulation of the larvæ of the house-fly in her nostrils, insufflations of calomel and of salt water proving ineffectual, the vapor of chloroform caused the *maggots* to be discharged (*Med. Record*, xvi. 326).

Administration.—No food should be taken by the patient for 4 hours previous to the administration of chloroform, and then in small quantity and of a digestible nature. Immediately before the chloroform is inhaled a draught of brandy or whiskey and water should be given. The first portion of vapor should be largely diluted with air, or, in other words, the full effect of the anæsthetic should be reached gradually in this manner, and not by intermitting its administration. A too rapid inhalation of it tends to produce symptoms of asphyxia. It should always be given by some one who is in the constant habit of using it, and who will attend to it alone (Osborn). Chloroform vapor should be administered by means of a napkin folded into a funnel-shape, and held closely over the nostrils and the mouth during inspiration, yet so as to admit a sufficient supply of atmospheric air; and in every case the patient should be in a recumbent position. To protect the skin of the face from irritation it should first be anointed. The quantity of chloroform used must vary with numerous conditions, but in surgery chiefly with the duration and painfulness of the operation. An intermittent administration prolongs unduly the ante-anæsthetic stage. The best guide is the condition of the pulse and the respiration; if these are normal and unembarrassed, the administration may be continued, provided the pulse warrants it by its strength and regularity. No more chloroform should be administered than is necessary to produce and preserve the requisite degree of anæsthesia. W. R. Williams (*British Med. Jour.*, 1883) lays down as the most important rules: 1. In chloroformization too much air cannot be admitted; in etherization as much as possible should be excluded. 2. The full effects of chloroform cannot be obtained in less than 15 minutes; those of ether are secured in 5 minutes. 3. The epigastrium should be bared, so that the respiratory movements may be accurately watched. 4. The indications furnished by the pulse appear too late to be practically useful. In 1879, Claude Bernard originally suggested the use of morphine to intensify and prolong chloroform-anæsthesia. Its effects were clinically demonstrated by Nussbaum and others, and still earlier by Labbé, who administered hypodermically $\frac{1}{4}$ grain of morphine 15 or 20 minutes before the inhalation of chloroform was commenced, and concluded that this method dispensed with the use of a large amount of chloroform and avoided its dangers (*Annuaire de thérap.*, xxxiii. 56). In 1879, Bossis contended that this method produced complete analgesia without altogether suspending consciousness or the senses of touch, sight, and hearing (*Bull. de thérap.*, xcvi. 476). Finally, Dr. Crombie reported the results of his extensive use of the method in India, where, however, he did not administer the morphine until the inhalation of chloroform had commenced. He fully concurred with previous reporters in regarding it as safer and more convenient than the use of chloroform alone. (For details see *Practitioner*, xxv. 401.) In 1880, Fraser advised the hypodermic injection of $\frac{1}{120}$ to $\frac{1}{60}$ grain of sulphate of atropine and $\frac{1}{12}$ to $\frac{1}{6}$ grain of acetate or hydrochlorate of morphine 15 or 20 minutes before the administration of chloroform is commenced (*ibid.*, xxvi. 210). The hypodermic use of chloroform is certainly efficient, but there are two dangers associated with it: the first is of throwing the liquid into a vein; the second is the production of local inflammation and abscess, and even gangrene. These dangers may be lessened, the former by puncturing the skin with the tube unattached, and waiting to see that no blood escapes from it, the other by avoiding to wound the lower surface of the skin. The dose thus administered has varied from 15 to 60 grains (Gm. 1-4).

There is no medicinal antidote to chloroform. It destroys life more or less gradually by asphyxia or more or less rapidly by syncope. For the former condition artificial respiration is the appropriate remedy. For the latter the essential treatment consists in instantly placing the patient in such a position as will cause the blood to flow into the brain. It has been proposed by Dr. G. E. Sanford (1878) to counteract the dangers of chloroform by administering it mixed with nitrite of amyl, in the proportion of 1 pound of the former to 2 drachms of the latter. After having employed it in a number of surgical operations and obstetrical cases, he arrived at the conclusion that "it seems to be fully as safe as sulphuric ether, and far more pleasant in its administration, possessing all the advantages of pure chloroform, but without its dangers." Burrall refers to nine

cases, in all of which impending death seems to have been averted by nitrite of amyl inhaled or injected hypodermically (*Med. Record*, xxi. 235). In some cases the symptoms have been removed by titillating the nostrils with a feather or by the emanations of ammonia (Schirmer); and a case is reported of reaction from alarming syncope induced by swallowing a fluidounce of chloroform "after four half-drachm injections of liquor ammoniæ (*B. P.*)" had been introduced into the veins of the arm. The patient, however, died (*Times and Gaz.*, May, 1871, p. 616). Billroth and many other surgeons endeavor to prevent the dangers of chloroform by diluting it with ether and alcohol. A mixture of 3 parts of chloroform, 1 of sulphuric ether, and 1 of alcohol is often employed. But a death under the use of this mixture occurred to Billroth himself in a case of attempted reduction of a dislocation of the hip-joint (*Boston Med. and Surg. Jour.*, Dec. 1880, p. 649).

CHLORODYNE is the name given to a popular nostrum which is much used for the relief of flatulent colic, and generally as an anodyne. According to E. Smith (1870), its composition is as follows: $\mathcal{R}$. Chloroformi $\mathfrak{z}$ iv; morphiæ mur. gr. xx; æther. rect. $\mathfrak{z}$ ij; ol. menthæ pip. $\mathfrak{m}$ viii; acid. hydrocyan. dil. $\mathfrak{z}$ iv; tinct. capsici $\mathfrak{z}$ vj; mucil. acaciæ $\mathfrak{z}$ j; theriacæ [syr. fusc.] ad $\mathfrak{z}$ iv.—*M.* Such a combination is often useful, but is too dangerous to be entrusted to ignorant persons.

CHONDRUS, U. S.—IRISH MOSS.

Carrageen, P. G.; *Caragahan*, *Fucus crispus*.—*Carragaheen*. *Mousse marine perlée*, Fr.; *Irländisches Moos*, *Perlmoos*, *Knorpeltang*, G.

The entire plant, *Chondrus* (*Sphærococcus*, *Agardh*, *Fucus*, *Linné*) *crispus*, *Lyngbye*, and *Chondrus* (*Sphærococcus*, *Agardh*, *Mastocarpus*, *Kützinger*) *mamillosus*, *Greville*, s. *Gigartina mamilliosa*, *J. G. Agardh*. Bentley and Trimen, *Med. Plants*, 305.

Nat. Ord.—Algæ, Florideæ.

Origin.—These plants grow on rocks of the American and European shores of the Atlantic Ocean, and are collected in the spring on the coasts of New England and Ireland. On the coast of Massachusetts about 15,000 barrels of Irish moss are stated to be annually collected.

Description.—Both plants are attached to the rocks by means of a small disk. The frond, about 6 to 8 or 12 inches (15 to 20 or 30 Cm.) long, is cylindrical below, repeatedly forked above, flattened, and gradually dilated, acquiring a width varying at the forks between $\frac{1}{8}$ and 1 inch (3 and 25 Mm.), and across the branches between $\frac{1}{16}$ and $\frac{1}{4}$ inch (2 and 6 Mm.); the final lobes are linear or more or less broadly wedge-shaped, emargi-

FIG. 63.

Chondrus crispus, broad form.

Narrow form, with fruit.

Chondrus mamillosus, with fruit.

nate or two-lobed, and ragged or crisp at the rounded margin from newly-forming segments. The capsules (cystocarps or sporocarps) of *Ch. crispus* are imbedded near the end of the segments and project slightly above the surface; those of *Ch. mamillosus* are scattered along the channelled branches of the frond, are oval or elliptic, and raised upon a

short stalk. In the fresh or softened state both plants are cartilaginous, of a brownish or purple, or frequently yellow or green, color. After washing in water and drying in the sun they turn whitish or yellowish, and become somewhat translucent and of a horny appearance. The drug has a slight seaweed-like odor and a mucilaginous somewhat saline taste. 1 part (15 grains) of it boiled with 30 parts (1 fluidounce) of water yields a solution which after cooling forms a thick mucilage; and with 20 parts (5½ fluidrachms) (or 1 part of the well-dried drug with 30 parts) of water gelatinizes on cooling.

Constituents.—The principal constituent is mucilage, of which Herberger (1834) obtained near 90 per cent., 9.5 of which were soluble in cold water. The mucilage is precipitated by lead acetate, and yields mucic acid on being treated with nitric acid. Flückiger found the mucilage to contain 0.88 per cent. and the whole plant 1.012 per cent., of nitrogen. The same author obtained over 15 per cent., Herberger only 8.8 per cent., of ash, which the latter found to consist of chlorides, sulphates, and phosphates of sodium, potassium, calcium, and magnesium. Grosse detected also traces of iodine and bromine. Church (1877) determined in the air-dry drug 6.4 per cent. of sulphur, a portion of which is present as sulphates; also 9.38 albuminoids, 55.54 mucilage, 2.15 cellulose, 14.15 ash, and 18.78 water. Starch is absent, and the decoction is not colored blue by iodine; yet after treating thin sections of the drug for a day with alcoholic solution of potassa, and then washing with water, the cell-contents, but not the cell-walls, acquire a dark-blue color on being left in contact with solution of iodine (Flückiger).

Admixtures.—Other Algæ are not unfrequently collected with the officinal species, and are in most cases readily distinguished from the latter: those of similar appearance are *Gigartina acicularis*, *Lamouroux*, with slender cylindrical branches, and *Gig. pistillata*, *Lamouroux*, with prominently stipitate capsules.

Allied Drugs.—*Dulse* is the name given to *Hallymenia* (*Fucus*, *Linné*, *Rhodoménia*, *Greville*, *Sphaerococcus*, *Kützinger*) *palmatus* and *edulis*, *Agardh*, two floridous Algæ growing on the coasts of the Atlantic and Mediterranean. Both are of a deep blood-red, or after drying dark-purple, color, and have flattened fronds, that of the first species being palmately divided into oblong, wedge-shaped lobes. Stenhouse (1844) found it to contain mannit, and Magin-Bonet proved the presence of bromine and iodine.

HELMINTHOCHORTON, CORSICAN MOSS. This consists partly of *Sphaerococcus* (*Fucus*, *Linné*, *Ceranium*, *Willdenow*, *Gigartina*, *Lamouroux*, *Alsidium*, *Kützinger*) *Helminthochortos*, *Agardh*, which grows in the Mediterranean, but as found in commerce is always a mixture, sometimes of twenty or thirty different species of Algæ. The drug is cartilaginous, filiform, repeatedly forked, varies in color between brown, yellowish, and whitish, and has the odor of sea-weeds and a strongly saline and mucilaginous taste. It is known to contain mucilage, gelatinous principles, and various salts, among them bromides and iodides, but its anthelmintic principle, if any, is unknown.

FUCUS AMYLACEUS, CEYLON MOSS, also called *jaffna* and *edible moss*, comes from the Indian Ocean, and consists of *Sphaerococcus* (*Plocaria*, *Montag*, *Gracilaria*, *Greville*) *lichenoides*, *Agardh*. It is about 4, sometimes 8 or 10, inches (10, 20, or 25 Cm.) long, about $\frac{1}{16}$ inch (1.5 Mm.) thick, cylindrical, rather irregularly forked, filiform above, and has in the fresh state a reddish color, but on drying becomes nearly white and rather brittle. It has a slight sea-weed odor and a mucilaginous taste. The latest analysis is by H. G. Greenish (1882), who, besides moisture 15, ash 10.2, albuminoids 7.5, and matter soluble in alcohol 0.1 per cent., determined the absence of mannit and the presence of various carbohydrates differing in their behavior to water and alkalies and in the sugar they yield with acids—namely, metarabin 1.32, and others soluble in soda 3.12: gelose and others soluble in hot water 36.7: paramylon 6.5, wood-gum 3.2, and cellulose 10.2 per cent.

An allied drug is the *agar-agar* of Celebes, which consists of *Eucheuma spinosum* and *E. gelatinæ*. *Agardh*, is of a brownish-white color, and has thorn-like projections on the branches. The so-called *Japanese* or *Chinese gelatin* or *isinglass* is prepared from the two Algæ named and from several other species.

EDIBLE BIRDS' NESTS are the nests of *Collalia* (*Hirundo*) *esculenta* and several other swallows of the Indian Archipelago, and consist of different species of *Gelidium* and allied sea-weeds after they have been altered in the crop or gizzard of the bird. They contain a large amount of gelatinous matter.

Pharmaceutical Preparation.—**GELATINA CARRAGEEN, P. G.**—Irish moss jelly. *E.*—1 part of Irish moss is boiled for half an hour in 40 parts of water; the decoction is expressed, mixed with 2 parts of sugar, and evaporated to 10 parts.—*P. G.*

Carrageen gelatin dried in sheets has been used as a substitute for other fomentations and poultices. A piece of convenient size is placed between two pieces of cotton cloth or flannel, then dipped in hot water, pure or medicated, until it is saturated, and then applied to the skin and covered with waterproof cloth. *Ceylon moss* is identical with carrageen in its qualities.

Medical Action and Uses.—Carrageen is demulcent and slightly nutritious. Its nutritious elements exist in an exceedingly minute proportion. It once had an extensive reputation in the treatment of chronic *bronchial* and *intestinal fluxes* and irritations of the *urinary passages*. The degree of its efficacy in these affections was probably due to its protective qualities, and possibly also to the influence of its iodic constituent upon nutrition, which has generally been admitted, but not demonstrated. The following preparation is agreeable and useful: Irish moss, macerated and washed, gr. xxx; pure water ℥xvj; boil down to one-half and strain with expression, and add white sugar ℥iv; gum-arabic ℥j; powdered orris-root gr. xxx; heat to dryness with a gentle temperature, stirring constantly so as to obtain a pulverulent mass, to which 3 ounces of arrowroot should be added with trituration. To prepare a jelly with this powder, rub a teaspoonful of it with a little cold water and then pour a cupful of boiling water on it (Neligan).

Helminthortocum, as its name indicates, is used as a *vermifuge*, and is given in coarse powder, mixed with honey or milk, in the dose of from 15 to 150 grains (Gm. 1.0–10.0). It is also used, in decoction, for induration of the *lymphatic glands*.

CHRYSAROBINUM, U. S., P. G.—CHRYSAROBIN.

Chrysarobine, Fr.; *Chrysarobin*, G.

A mixture of proximate principles extracted from Goa-powder, a substance found deposited in the wood of the trunk of *Andira Araroba*, *Aguiar*.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—The *po' de Bahia*, *araroba* or *arariba* tree, is closely allied to the West Indian cabbage tree (see page 202), and is common in the damp forests of Bahia, Brazil, where it is locally known as *angelim amargoso*. It attains a height of about 100 feet (30.5 M.), has long petioled paripinnate leaves and paniculate racemes of purple flowers with a one-ovuled ovary. It was first described by Aguiar (1879), but Monteiro (1878) had recognized it already as being distinct from *Andira anthelmintica*, *Benth.*, and from *And. vermifuga*, *Martius*, known in Brazil as *angelim doce*. According to Peckolt (see *ANDIRA*), the former, and according to F. M. de Mello Oliveira (1878) both species named, are known in Brazil as *angelim amargoso*. Oliveira gives *urucema* as the common name of *And. spectabilis*, and Martius mentions in his *Materia Medica of Brazil* that the name *araroba* is given to two species of *Centrolobium* (*C. robustum* and *C. tomentosum*).

ARAROA is contained in the large porous vessels and in clefts or cavities which traverse the wood in the direction of the diameter and are prolonged through the entire trunk; it is obtained by cutting down the tree, splitting the trunk, and scraping the powder from the clefts, and is seen in commerce as a rough powder or in small irregular pieces, originally of a light-yellow color, but usually darkened by exposure to light and moisture to a dull-ochrey, pale-brown, or even umber-brown or deep-purple, color. It has a bitter taste. When carefully heated it yields a moss-like sublimate, which is colored red by alkalis. Formerly it was largely exported from Brazil to Portugal, whence it appears to have been shipped to the Portuguese colonies in Africa and Asia, and from the settlement Goa on the Malabar coast it became known in East Indian pharmacy, and subsequently in European and American, as Goa-powder; its identity with *araroba* was first pointed out by Dr. Da Silva Lima (1875); the wood to which the powder is attached was found by E. M. Holmes to be very similar to that of *Cæsalpinia echinata*, *Lamarck*; but J. L. Macmillan (1879) observed that this wood yields its coloring matter to water, while *araroba* does not. Examined by Prof. Attfield (1875), *araroba* was found to be free from starch, to leave only .43 per cent. of ash, and to yield to boiling water about 7 per cent. of gum, a glucoside precipitable by lead subacetate, and a bitter principle precipitated by lead subacetate; from the residue benzol dissolves over 80 per cent. of chrysarobin, and alcohol afterward takes up 2 per cent. of resin, leaving 5½ per cent. of red wood-fibre.

Properties.—Chrysarobin is “a pale orange-yellow, crystalline powder, permanent in the air, odorless and tasteless, almost insoluble in water, only slightly soluble in alcohol, readily soluble in ether and in boiling benzol. When heated to about 162° C. (323.6° F.) it melts, and may be partially sublimed. On ignition it is wholly dissipated. In solutions of alkalis it is soluble with a yellowish-red or reddish-yellow color, which is changed to red by passing air through the liquid. Sulphuric acid dissolves it with a deep blood-red color; on pouring the solution into water the substance separates again unchanged.”—*U. S.* The dust of chrysarobin is irritating to the eyes and nostrils.

As obtained from *araroba* by hot benzol, chrysarobin was by Attfield supposed to be

chiefly chrysophanic acid, until Liebermann and Seidler (1878) showed it to be mainly a hitherto unknown compound, $C_{30}H_{26}O_7$, for which they retained the name chrysarobin proposed by Attfield. It is a pale-yellow powder, consisting of small wart-like crystals and acquiring on exposure a darker tint. By repeated crystallization from glacial acetic acid it is obtained pure in the form of small yellow scales, which are fusible and partly sublimable, nearly insoluble in water and ammonia, sparingly soluble in alcohol, more freely soluble in amylie alcohol, ether, collodion, chloroform, and various hydrocarbons. It is inodorous and, on account of its insolubility in water, tasteless. Chrysarobin dissolves in concentrated sulphuric acid with a yellow color, is nearly insoluble in very diluted potassa solution, and yields with melted potassa a brown mass. Chrysophanic acid, on the other hand, dissolves in concentrated sulphuric acid and in very dilute potassa solution with a red color, and on being melted together with potassa yields a blue mass. The solution of chrysarobin in strong potassa solution has a yellow color and a strong green fluorescence, and on being agitated with atmospheric air rapidly acquires a red color, through the formation of chrysophanic acid; $C_{30}H_{26}O_7$ (chrysarobin) + $2O_2$ yields $2C_{15}H_{10}O_4$ (chrysophanic acid) + $3H_2O$.

Tests.—If boiled with 2000 parts of water, chrysarobin should not be completely dissolved; the filtrate should be pale reddish-brown, tasteless, neutral to test-paper, and should not be colored by ferric chloride. Chrysarobin should be almost wholly soluble in 150 parts of hot alcohol. If .001 Gm. ($\frac{1}{64}$ grain) of chrysarobin be sprinkled upon a drop of fuming nitric acid, the red solution extended to a thin layer, and a little ammonia added by means of a glass rod, a violet color should be produced.—*P. G.*

Pharmaceutical Uses.—Chrysarobin, having been at one time mistaken for chrysophanic acid, is still occasionally prescribed by the latter name. It is an ingredient of Unguentum chrysarobini, *U. S.*

ACETUM ARAROBÆ, *vinegar of araroba*, is prepared by Da Silva Lima by digesting for a week 25 parts of araroba in 100 parts of diluted acetic acid. When used it may be mixed with glycerin.

Medical History.—In British India, in 1874, attention was called to a secret medicine known as Goa-powder and po' de Bahia, and which was found to be very efficacious in certain chronic diseases of the skin. Investigation showed that it was known in Brazil as araroba, and esteemed as a remedy for various cutaneous affections, and especially for *herpes circinatus*, *chloasma*, and *intertrigo*.

Physiological Action.—It is stated that the irritating effects of araroba on the skin and mucous membranes are such that the workmen employed in cutting up and pounding it are obliged to protect the face, nostrils, and throat against its dust. Gas-koin relates that in treating ringworm of the scalp he first wetted the part thoroughly with lemon-juice or carbolic acid water, and for a few minutes rubbed in the powder, after which the face was apt to become swollen and covered with an ugly brown stain, accompanied by considerable inflammation. This effect was observed oftenest in children. In some cases, although the paste was applied to the hairy scalp only, the whole face and shoulders became stained of a dark purple-gray, which was speedily removed by desquamation. Yet Mr. Squire declares that Goa-powder and chrysophanic acid (chrysarobin) applied to the sound skin occasion no irritation, and that they may be used upon a raw surface as a salutary stimulant. The usual experience with chrysophanic acid (chrysarobin) is that when applied to the face or scalp it is very apt to occasion redness of the eyes and erythema with swelling of the skin, followed by desquamation of the cuticle. The inflammation is sometimes intense and painful, producing a crop of boils and lasting for several weeks. Applied to the broken skin, as in psoriasis, it has been known to excite vomiting. Its absorption was also supposed to be shown when in a case of general psoriasis, although the preparation was applied only to one side of the body, it cured the eruption of the opposite side, which had been carefully wrapped up in cotton wool (Charteris). In the same or a similar case it also occasioned gastro-intestinal symptoms.

Internally, chrysophanic acid is by some alleged to be purgative in the dose of 7 grains (Gm. 0.50). It is stated, however, to be very slow in its operation, which begins only at the end of 24 hours, but may continue for several days, without griping. It is more apt to act at first as an emetic when given to children of twelve years in doses of 6 grains, and to adults in doses of 25 grains, according to Thompson, who adds that chrysarobin is likely to purge and chrysophanic acid to vomit (*British Med. Jour.*, May, 1877, p. 607). A case is reported in which after a 3-grain dose of chrysophanic acid a woman was seized with burning pain in the stomach, vomiting, pain in the bowels, diarrhœa,

hamaturia, and pain over the bladder, with tenesmus (*Glasgow Med. Jour.*, Oct. 1881). It is probable that the substance taken was not chrysophanic acid merely.

Medical Uses.—The use of Goa-powder in *ringworm of the scalp* is thus described by Dr. Fayrer: A few grains of the powder are mixed with common vinegar or lemon-juice to about the consistence of cream, and with it the eruption is painted over, as well as the skin a little distance beyond its margin. It causes no pain at first, but in the course of a few hours there is a sensation of a dull, heavy nature, the eruption becoming white, while the surrounding skin is stained of a dark color. The sense of uneasiness soon passes away, the integument resumes its natural color, and all traces of the disease disappear at the same time. In chronic cases the process of cure is necessarily more gradual. Da Silva Lima has verified these statements, and also tested the virtues of the application in an obstinate case of *mentagra*, in which he twice a day applied to the roots of the affected hairs, by means of a camel's-hair pencil, an ointment composed of 20 grains of araroba-powder, 10 drops of acetic acid, and an ounce of benzoïn ointment.

Chrysarobin has been oftener used in the treatment of *psoriasis* than of any other disease of the skin. When Goa-powder was employed, 1 part of it was mixed with 3 of lard, and applied with friction twice a day for 6 successive days. An ointment made with from 10 to 60 grains (Gm. 0.60–4) of chrysarobin to an ounce of lard may be applied to the patches only with a mop night and morning, after removing the scales with warm water. It should not be used on the face and head, on account of the discoloration of the skin it produces.

To prevent irritation of the sound skin, a paste made by adding only a small quantity of water to the acid may be applied to the patches alone, and when dry it may be covered by a film of collodion, which will preserve it for several days (Fox). Continued experience in the use of chrysarobin has not increased confidence in its virtues. Besides the objectionable discoloration and inflammation of the skin produced by it, the eruption, after being cured, is apt to break out anew and more extensively (Jarisch, *Centr. bl. f. Therap.*, i. 14). These conclusions are confirmed by Morrow (*Amer. Jour. of Med. Sci.*, Apr. 1883, p. 565). Napier claims that cases of *psoriasis* which had resisted arsenic and external applications were cured by chrysophanic acid administered in pills containing half a grain each of the preparation. At first, one was given after each meal, and the dose gradually increased until signs of gastro-intestinal disturbance occurred. In one case 9 grains a day were taken without trouble. In nearly all the cases the improvement of the skin disease was marked and rapid (*Practitioner*, xxix. 132). Externally, the medicine has proved its efficacy in the treatment of contagious or parasitic *ringworm*, and is more or less useful in that of *herpes tonsurans*, *herpes circinatus*, *chronic lichen*, and the *ophioides* of pregnancy. It seems to possess no special virtues in *pityriasis*, *acne*, *eczema*, or *tinea versicolor*.

Administration.—Originally, Goa-powder was made into a paste with a little vinegar or lemon-juice and smeared over the eruption daily for several days. Afterward an ointment was used containing from 10 to 60 grains (Gm. 0.60–4) of the powder, or of chrysophanic acid (chrysarobin) melted together with an ounce of lard. The official chrysarobin ointment is preferable. Better still is probably the gelatin mixture proposed by Pick, containing from 5 to 15 per cent. of chrysarobin. Its action can be confined to the affected spot (Jarisch, *loc. cit.*).

According to Liborius, a tincture made from the fibres of a Siamese plant, *Rhinacanthus communis*, which contains chrysarobin, may be used to cure *ringworm*.

CICHORIUM.—CHICORY.

Succory, E.; *Chicorée*, Fr.; *Cichorie*, G.

The root of *Cichorium Intybus*, Linné.

Nat. Ord.—Compositæ, Cichoreæ.

Origin.—Chicory is a perennial herb indigenous to Europe and the Levant and extensively naturalized in North America. The stem is about 3 or 4 feet (.9 to 1.2 Mm) high, with spreading branches. The leaves are oblong or lanceolate, the lowest lyrate-lyruncinate, the upper one sessile, clasping, toothed, or entire. The flower-heads are in axillary clusters of two or three, have a double involucre, blue or whitish ligulate, and five-toothed florets and striate akenes, with a chaffy pappus. It flowers from June to October. The root should be collected late in autumn or early in spring.

Description.—The root of the wild plant soon becomes woody; that of the cultivated plant remains fleshy and has a thicker bark. It is several-headed, 10 to 12 inches

(25 to 30 Cm.) long, somewhat branched, longitudinally wrinkled, light-brown externally and whitish internally. The bark is rather thin, white, radially striate from the dark-colored milk-vessels and by a brown cambium-line separated from the finely porous yellow wood, marked by fine medullary rays and one or more annual layers. The root is inodorous and has a mucilaginous and bitter taste. From 3,500,000 to 4,000,000 pounds of chicory are annually imported into the United States from Europe. It is not unfrequently sold as dandelion-root, from which it is distinguished by its lighter color, its thinner bark, and its radiating milk-vessels. Much of it is used for the adulteration of coffee.

Constituents.—Chicory-root contains, besides the ordinary constituents of vegetables, inulin and a bitter principle which has not been isolated. The cultivated root, collected in the beginning of July, was found by Dragendorff to contain 36 per cent. of inulin. This principle being readily saccharified by the influence of diluted mineral acids, chicory-root has recently (1882) been proposed as a source of alcohol, which is said to be easily obtainable in a state of purity and possessed of a pleasant aromatic taste. Nietzki (1876) separated from the flowers a crystalline colorless glucoside, which he found to be insoluble in ether, freely soluble in hot water and alcohol, and with a golden-yellow color in alkalis.

Allied Species.—*Cichorium Endivia*, *Linne*—Endive, *E.*; Scarole, *Fr.*; Endivie, *G.*—is a native of the Levant and cultivated for salad. The leaves are obovate and finely toothed, the upper ones lanceolate and entire. The blue flowers are axillary, one head being on a long and three or four on a short peduncle.

Medical Action and Uses.—Chicory is thought to increase the appetite, promote the digestion, and stimulate the liver—in a word, to operate very nearly as dandelion is supposed to act. Its excessive use is alleged to occasion venous congestion of the abdominal organs, the brain, and the organs of the senses. In this manner it has been accused of causing amaurosis. The fresh young plant is generally eaten, like endive, as a salad in the spring season, as a “purifier of the blood”—i. e. as a promoter of the secretions of the liver, bowels, and kidneys. Even from ancient times it has been recommended in cases for which dandelion is commonly used, including those of *feeble digestion* with flatulence, constipation, and light-colored stools—a condition supposed to denote torpor of the liver. It is alleged to have cured *intermittent* fevers which quinia failed to arrest, especially when engorgement of the liver and spleen was present, with general dropsy. It is also asserted to have been useful in chronic diseases of the *skin*, particularly in those of a gouty origin. Chicory-root dried, roasted, and reduced to a coarse powder has a close resemblance to ground coffee, and is extensively used for mixing with the latter or for fraudulently adulterating it. To those who are not aware that the proper flavor of coffee depends upon its aromatic volatile oil, and who measure its strength by its bitterness, the substitution of chicory can work no disappointment or injury. Very probably an infusion of chicory taken at meals as a substitute for coffee would be preferable to the latter on the score of health, and it is still more probable that pure water would be more wholesome than either; but such facts furnish no reason why the public should be deluded into believing that in drinking an infusion of chicory they are using a true substitute for coffee.

CICUTA.—WATER-HEMLOCK.

Cowbane, *E.*; *Ciguë vireuse*, *Fr.*; *Wasserschierling*, *G.*

The herb of *Cicuta virosa*, *Linne*, s. *Cicutaria aquatica*, *Lamarck*. Bentley and Trimen, *Med. Plants*, 119.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—Water-hemlock is a native of the northern section of the northern hemisphere, and is found in America from Canada northward. It grows in swamps and wet places, has a short, thick, rather ovate, hollow rhizome beset with circles of thin rootlets, and flowers from July to September.

Description.—The stem is about 40 inches (1 M.) high, hollow, often purplish. The leaves are on sheathing petioles, bright-green, and smooth, triangular-oblong in outline, twice or thrice pinnate, the leaflets opposite, narrow lanceolate, narrowed at both ends, sharply serrate, and the teeth with whitish points. The umbels are large, compound, the flowers small, white, and the fruit subglobose, laterally flattened, with thick corky ribs, and six oil-tubes in each mericarp, the two on the face being very thin. The herb has a slight aromatic odor and a somewhat aromatic and acrid taste.

Constituents.—Polex, Wittstein, and Buignet have observed the presence of a vola-

tile alkaloid, *cicutine*, which, however, according to Van Ankum (1868), does not exist in the root. The fruit yields about 1½ per cent. of a volatile oil which was proved by Trapp (1858) to be identical with oil of eumin. *Cicutoxin* is a tenacious, non-drying, amorphous, resinous principle in bright yellow drops, which is contained in the resinous cortical zone of the rhizome. It was isolated by Van Ankum, and further examined by Boehm and Trojanowski (1877); it is insoluble in petroleum benzin, but dissolves readily in alcohol, ether, and chloroform; also in hot water and in alkalies. The dried root yields about 3.5 per cent. of it.

Allied Plants.—*CICUTA MACULATA*, Linné—*Spotted water hemlock*, *Spotted parsley*—is a common perennial of North America, and is distinguished by its elongated, fleshy, tuberous roots, the purplish spotted stem, and the broader leaflets. Its properties are similar to those of the preceding species. J. E. Young (1855) obtained from the fruit a volatile alkaloid which he regarded as being identical with *conine*.

Sium latifolium, Linné—*Water-parsnip*—is a European perennial, probably indigenous to California; the nearly-allied *S. lineare*, Michaux, which is a native of North America, has been often mistaken for it. Another poisonous species, *S. angustifolium*, Linné, is indigenous to Europe and North America. The subterraneous portion of the California plant was examined by A. R. Porter (1876), who found in it an aromatic volatile oil, and attributed its poisonous properties to a resinous body. These results were in the main confirmed by N. Rogers (1876), who in addition obtained a non-poisonous volatile alkaloid resembling Wittstein's *pastinacine*: but according to Porter, this is probably ammonia.

CENANTHE CROCATI, Linné (Bentley and Trimen, *Med. Plants*, 124)—*Water-dropwort* or *dead-tongue*, also known as *water-hemlock*—is a European perennial, with fleshy fusiform roots containing a yellow juice, roundish-obovate, wedge-shaped, lobed, or toothed leaflets, and oval-oblong fruits, which are crowned with the long erect style, have thickened lateral ribs and six oil-tubes in each mericarp. *Enanthin*, an acrid and emetic principle, was observed by Gerding (1849) in *Cenanthus fistulosa*, Linné, and is probably an impure alkaloid.

Physiological Action.—It is only since 1876 that the source and operation of the poisonous elements of this species have been rendered clear by the investigations of Boehm. Before that date it was well known that the root of the fresh plant is its most active part, although the stalk and leaves are scarcely less poisonous. Administered to dogs, the root is found to cause salivation, vomiting, diarrhoea, and tetanoid convulsions, followed by resolution; in man it produces essentially the same effects, with the addition of syncope and strabismus. A child six years old, having eaten some of the root of this plant, suffered from burning pain in the stomach, lost sensation and consciousness, expelled his urine forcibly, and then was seized with violent tetanic convulsions, with grinding of the teeth, strabismus, and bleeding from the ears. Death occurred within half an hour. In various fatal cases it is reported that the gastro-intestinal mucous membrane was inflamed, and even ulcerated and gangrened; but it is possible that these appearances, if they existed, were due to the mechanical irritation of the ingested root. Certain it is that in a recent fatal case no lesions of the sort were found (Trojanowski). More important is the extreme engorgement of the lungs and of the right side of the heart, and to a great extent of the brain also, which always occurs—a fact which denotes that the agent is a heart-poison.

It was long since demonstrated that the oil in which this plant abounds is destitute of poisonous qualities, and that, on the other hand, they are fully possessed by the alcoholic resinous extract. They appear to depend upon a principle which has been called *cicutoxin* (Trojanowski). It is so slowly absorbed from the digestive organs that full 20 minutes elapse after the administration of a fatal dose before its characteristic effects begin to appear. It does not produce any irritation of the fauces or of the stomach. When injected hypodermically it acts still more slowly than by the stomach. It is partially absorbed by the intact skin of frogs. Injected into the veins of animals, its operation is almost instantaneous.

Injected subcutaneously in frogs in the dose of from 1 to 3 Mg., in from 20 minutes to 1½ hours *cicutoxin* produces tonic and clonic convulsions alternately, and if the animal dies it is in a state of complete resolution. Meanwhile, the respiration is very hurried, the inspiratory so far exceeding the expiratory act that the animal becomes distended with air. During the spasms the heart's action is suspended in diastole. In mammals poisoned by *cicutoxin* the first symptom, occurring in about half an hour, is profuse salivation, with signs of distress, presently followed by a slight quivering or jerking of the muscles, which passes into violent spasm if the animal is irritated. Breathing grows very rapid and signs of suffering are manifested, when suddenly violent tonic and clonic spasms supervene, with frothing at the mouth from the agitation of the saliva; the respiration is suspended by spasm of the respiratory muscles, the urine is violently

expelled by a similar action of the abdominal muscles, and the heart acts so violently that its impulse may be heard at the distance of several feet. After a minute or two the spasms subside, and the animal lies exhausted and breathes deeply, or walks staggering until overtaken by a fresh paroxysm, which still further restricts the function of the lungs, and death by asphyxia and convulsion takes place. With smaller, non-lethal doses there may be no convulsion, but only wandering spasms of the muscles over all the body.

Medical Uses.—This plant, in consequence partly of its poisonous qualities, and partly because its efficacy is not established, is hardly ever used internally. It is said to be employed by the Kamtschadales as a topical adodyne in *rheumatism*, and others have applied it for a similar purpose in *gout* and *neuralgia*.

CICUTA MACULATA.—A case is reported of poisoning with the root of this plant, mistaken for angelica. The symptoms were delirium; cold skin; pulse 46, thready, and scarcely perceptible; vomiting of blood and mucus; a haggard and pale countenance; and complete prostration. Recovery took place after the internal and external use of stimulants and the hypodermic injection of morphia (*Med. News*, xl. 524). Linnæus ascribed narcotic qualities to *Sium latifolium*, and it has been used to treat diseases of the skin. *Cenanthe crocata* has been the cause of a great many cases of poisoning in Europe, where its root is apt to be eaten by mistake for that of parsnip, celery, radish, carrot, etc. Hogs, cows, and horses have frequently been killed by it. It excites a burning pain in the throat and stomach, nausea and vomiting, and sometimes purging, vertigo, delirium, coma, and violent convulsions, with trismus and bloody foam on the lips, while consciousness and sensibility are lost. Respiration is labored, the face cyanosed, the pupils dilated, the pulse small. Death occurs in asphyxia, with convulsions. The bruised root has been applied to hæmorrhoidal swellings. In poisoning by any of these plants the stomach should be emptied at once by emetics, and anæsthetics and narcotics used to control the spasm. (Compare Leme, 1857, and Falck, 1880.)

CIMICIFUGA, U. S.—CIMICIFUGA.

Black snakeroot, Black cohosh, E.; Racine d'actée à grappes, Fr.; Schwarze Schlangenzwurz, G.

The rhizome and rootlets of *Cimicifuga racemosa*, *Elliott*, s. *Cim. Serpentaria*, *Pursh*, s. *Actæa racemosa*, *Limé*, s. *Macrotys actæoides*, *Rafinesque*. Bentley and Trimen, *Med. Plants*, 8.

Nat. Ord.—Ranunculaceæ, Acteæ.

Origin.—A perennial herbaceous plant growing in rich woodlands of the United States and Canada. The slender stem is 6 to 8 feet (1.8 to 2.4 M.) high, is leafless below and above, and bears near the middle several large, petiolate, thrice-ternate leaves, with ovate-oblong, acute, and deeply-toothed leaflets. The white flowers are in terminal racemes 8 to 12 inches (20 to 30 Cm.) long, have small clawed two-horned petals, numerous stamens on slender filaments, and usually one pistil, producing a dry capsular fruit containing many flat seeds. It flowers in June and July and ripens its fruit in September, after which time the rhizome should be collected.

Description.—The rhizome is about 2 inches (5 Cm.) long, and 1 inch (25 Mm.) thick, horizontal, somewhat flattened, with distinct nodes and numerous stout branches, the remains of overground stems, which are upright or curved upward, and increase the length of the underground portion to 6 inches (15 Cm.) or more. These branches are somewhat annulate by the prominent nodes, and are, according to their age, either hollow or have a cup-shaped, flat, or even convex, termination; like the rhizome, they are hard and tough, and break with a slightly fibrous nearly smooth fracture. The rootlets originate mainly from the nodes, are 6 to 10 inches (15 to 25 Cm.) long, the older ones $\frac{1}{2}$ inch (6 Mm.) in diameter near their place of attachment, mostly about $\frac{1}{12}$ inch (2 Mm.) thick; when dry of a wiry appearance, obtusely quadrangular, and longitudinally wrinkled; brittle, and break with a short fracture. The color of the fresh rhizome and root is dark-brown, becoming purplish-black or brown-black after drying, the stem-remnants of a grayish tint. It has a slight but heavy odor and a bitterish and acrid taste. As met with in commerce, the rootlets, and often also the rhizomes, are much broken.

FIG. 64.

Cimicifuga racemosa: transverse section through a branch of the rhizome and through rootlets.

The transverse section of the branches shows a large central usually dark-colored pith, which is surrounded by numerous almost linear wood-bundles, the whole being covered by a rather thin, firm bark. The rhizome itself has irregular-shaped wood-bundles and a thicker bark. The rootlets have a thick dark-colored bark and a white woody medullium, projecting with from five to two rays into the former; the largest number of rays is near the base, and gradually diminishes toward the tip of the rootlets.

Constituents.—Tilghman (1834), J. S. Jones (1843), and G. H. Davis (1861) analyzed black snakeroot, finding starch, some tannin, gallic acid (?), resin, a little volatile oil, and other widely-diffused principles. F. H. Trimble (1879) found tannin to be absent; a principle which is colored green-black by ferric chloride is not a glucoside, and the white precipitate of the aqueous infusion, after having been washed with water, is not colored by ferric salts; the portion of the resin which is precipitated by lead acetate yields a crystallizable acid. T. E. Conard (1871) obtained a crystalline principle which is insoluble in benzine, oil of turpentine, and bisulphide of carbon, slightly soluble in ether and water, and freely in chloroform and diluted and strong alcohol; its alcoholic solution has an intensely acid and sharp taste. It was obtained from the fresh root by exhausting it with alcohol, precipitating the tincture with subacetate of lead, removing excess of lead by sulphuretted hydrogen, evaporating the alcohol, washing the residue with benzine and water, and crystallizing the undissolved portion from alcohol after decolorizing with aluminium hydrate. It appears to be a neutral principle. It was isolated by L. F. Beach (1876) from the so-called *cimicifugin* or *macrotyn*, which is prepared by precipitating a concentrated tincture of cimicifuga with water.

Off. Prep.—Extractum cimicifugæ fluidum, Tinctura cimicifugæ, U. S.

Medical Action and Uses.—Cimicifuga appears to depress the nervous and vascular systems, in that it occasions, in large doses, vertigo, dimness of vision, nervous tremors, depression of the pulse, and more or less nausea, with increased pulmonary and cutaneous secretion. It was originally employed in the treatment of chronic pulmonary diseases, and particularly of *chronic bronchitis* with profuse purulent expectoration. In *chorea* independent of definite local disease there is no doubt of its efficacy when administered so as to produce its specific effects. Probably it is most useful in rheumatic chorea, since it has proved to be an efficient remedy for acute *articular rheumatism* when freely administered. It is also excellent in muscular rheumatism, and especially in *lumbago*. That it exerts a powerful impression upon the uterine system is rendered probable by the relief it affords to the symptoms of pelvic congestion which often are present during the decline of the *menstrual function*, and by its curing many cases of atonic *amenorrhœa* when its administration is duly prolonged. It is also alleged to be useful in the treatment of *seminal emissions*.

The average *dose* of cimicifuga is represented by 20 grains (Gm. 1.30) of its powder. This form is seldom used, a decoction or the fluid extract being preferred. The latter is officinal; the former may be prepared by boiling for a short time an ounce (Gm. 32) of the bruised root in a pint of water. 1 or 2 fluidounces may be given at a dose. The tincture is the least eligible of its preparations, but may be given in the dose of 30 to 60 minims.

CINCHONA, U. S.—CINCHONA-BARK.

Cortex cinchonæ, Cortex chinæ. P. G.—*Peruvian bark*, E.; *Quinquina*, Fr.; *Chinarinde*, G.

The bark of any species of *Cinchona* containing at least 3 per cent. (3.5 per cent., P. G.) of its peculiar alkaloids.

Officinal Kinds.—1. *CINCHONA FLAVA*, U. S.; *Cinchonæ flavæ cortex*, Br.; *Cortex chinæ calisayæ*; *Cinchona calisaya*, *Cortex chinæ regius*, *China regia*.—Yellow *Cinchona*, *Calisaya bark*, E.; *Quinquina calisaya*, *Quinquina jaune royal*, Fr.; *Calisayarinde*, *Königschina*, G.

The bark of *Cinchona Calisaya*, Weddell (containing at least 2 per cent. of quinine). Weddell, *Hist. Nat. des Quinq.*, plates 3, 3 bis, and 28; Bentley and Trimen. *Med. Plants*, 141.

2. *CINCHONÆ PALLIDÆ CORTEX*, Br.; *Cinchona pallida*, U. (*Plant. æquinoct.*, i. 33; Bentley and Trimen, *Med. Plants*, 140), and of *Cinch. micrantha*, Ruiz et Pavon (*Flor. Peruv.*, ii. 52).

3. *CINCHONA RUBRA*, U. S.—*Cinchonæ rubræ cortex*, Br.; *Cortex chinæ ruber*, China rubra.—Red cinchona, Red Peruvian bark, Red bark, E.; Quinquina rouge, Fr.; Rothe Chinarinde, G.

The bark of *Cinchona succirubra*, Pavon (containing at least 2 per cent. of quinine). Pavon, *Nueva Quinologia*; Howard's *Illustrations*, plate 9; Bentley and Trimen, *Med. Plants*, 142.

Nat. Ord.—Rubiaceæ, Cinchonææ.

Origin.—The genus *Cinchona*, as at present constituted, consists of about thirty-one or thirty-six species, all of which are indigenous to South America, from 10° north latitude to 19°, or probably 22°, south latitude. It follows the eastern slope of the central chain of the Andes from the southern limits, beginning in Bolivia, through Peru; and from about 2° south latitude in Ecuador, it occupies also the eastern slope of the western chain of the Cordilleras until by two narrow belts it enters the highlands of New Granada, whence it spreads north-east and northward into Venezuela, to the neighborhood of Caracas and in proximity to the Caribbean Sea. The climate in which the most valuable species are found is, according to Karsten (1858), characterized by a rainy season lasting for 9 months, heavy rains falling principally during the night and alternating with sunshine and fog through the day; during the remaining 3 months the temperature frequently sinks in the night to below the freezing-point, but reaches in the daytime 25° C. (77° F.), producing dense fogs. The mean annual temperature of these regions is 12° to 13° C. (about 55° F.). The less valuable species are found in regions in which the moisture is less evenly distributed throughout the year, and in which the mean temperature is higher, rising, according to Martius (1863), to about 20° C. (68° F.).

The cinchonas are not met with in the valleys; the lowest altitude observed by Karsten was at the northern limits of the cinchona region, where the valueless *Cinch. barba-coensis*, which is not a true cinchona, is at an elevation of 100 M. (330 feet). Caldas gives the highest limits at 3270 M. (10,700 feet), Karsten at 3500 M. (11,500 feet). The really valuable species, however, according to Weddell, grow at an altitude of 1600 to 2400 M. (5300 to 7900 feet); an exception is *C. succirubra*, which descends to about 700 M. (2300 feet). They are confined within about 11° to the north and south from Loxa, beyond which limits the barks are of little or no value. The most southern species is *Cinch. australis*, Weddell, the most northern ones *Cinch. tucujensis*, Karsten, and *C. cordifolia*, Mutis. All grow in the primeval forests either singly or with but few specimens together.

The cinchonas are evergreen trees or shrubs, most of the valuable species attaining a height of from 40 to 80 feet (12 to 24 M.). Their laurel-like opposite leaves have deciduous stipules, are entire at the margin, and vary in shape between lanceolate and roundish obovate, occasionally with a heart-shaped base. The petiole and the leaves are often purplish or red while young or before falling, and most of the valuable species (*Cinch. succirubra* is an exception) are pitted (scrobiculate) on the lower side in the angles formed by the prominent midrib with the lateral veins. The fragrant flowers form terminal panicles, and have a tubular often soft-hairy corolla, with the margin divided into five spreading lobes, and of a white-rosy or purplish color. The small five-toothed calyx crowns the ovate or oblong two-celled capsular fruit, which splits from the base upward to the persistent short calyx margin, and contains many flat and winged seeds. With several allied genera they constitute the tribe Eucinchonææ, which is characterized by the valvate præfloration, and with the two genera *Cascarilla* and *Remijia* they form a group in which the dehiscence of the fruit is septicial and the placentas are found upon the middle of the dissepiments, the principal distinction of the two genera being the dehiscence of their capsules from the apex downward. Most of the species are variable in their foliage and in other characters, and easily produce hybrids; hence the species form more or less distinct varieties, and are connected with one another by intermediate forms. The most important medicinal species are—

CINCH. CALISAYA, Weddell, discovered by Weddell (1847), a stately tree, is found in Bolivia and Peru, between 17° and 13° S. lat., at an altitude of 1500 to 1800 M. (5000 to 6000 feet), and has an ovate smooth capsule about $\frac{2}{3}$ inch (10 Mm.) long. At a higher elevation it forms the shrubby variety *Josephiana*, and in Bolivia is seen the variety *boliviana*, which has the lower surface of the leaves purplish. Several other varieties are distinguished, including *C. Ledgeriana*, which by some botanists is regarded as a

hybrid or even as a species, and the bark of which has attracted much attention for its richness in alkaloids.

C. OFFICINALIS, *Hooker filius*, the first species discovered by La Condamine (hence the name *Condaminea*), is a tree of about 15 M. (50 feet), and is found in Ecuador and Peru, principally near Loxa; its oblong capsules are ribbed and $\frac{1}{2}$ to $\frac{4}{5}$ inch (12 to 20 Mm.) long.

C. MICRANTHA, *Ruiz et Pavon*, and *C. SCROBICULATA*, *Humboldt et Bonpland*, are trees 10 and 20 M. (33 and 65 feet) high, met with in Peru, between about 13° and 4° S. lat.

C. SUCCIRUBRA, *Pavon*, 15 to 25 M. (50 to 82 feet) high, has oblong smooth capsules 1 or $1\frac{1}{4}$ inches (25 or 31 Mm.) long, and is chiefly confined to the western declivity of Chimborazo, but is found south to Northern Peru.

The barks of the above species constitute the official cinchona-barks. Several other species yield barks which are consumed in the manufacture of the cinchona alkaloids.

From his observations made in the cinchona-plantations of Java and the Himalayas, O. Kuntze (1878) endeavored to reduce the numerous recognized species of cinchona to four typical forms, regarding all others as hybrids; and he finds this view supported by the fact that hybrids capable of perpetuation by seed are known to exist in the plantations; his four species are named: I. *C. Weddelliana* = *C. Calisaya*, *Weddell*, in part (and perhaps *C. glandulifera*, *Ruiz et Pavon*); II. *C. Pavoniana* = *C. micrantha*, *Weddell* (and perhaps *C. nitida*, *Ruiz et Pavon*); III. *C. Howardiana* = *C. succirubra*, *Pavon* (and perhaps *C. purpurea*, *Ruiz et Pavon*); and IV. *C. Pahudiana* (as characterized by Howard).

Regarding Kuntze's views of the other species, we indicate here the supposed derivation of the best-known ones only: *C. pubescens*, *Vahl*, is a hybrid of III. and IV.; *C. officinalis*, *Hooker*, of II. and I.; *C. pitayensis*, *Weddell*, of II. and I.; *C. cordifolia*, *Mutis*, of III. and IV.; *C. lancifolia*, *Mutis*, of III. and I.; and *C. scrobiculata*, *Humboldt et Bonpland*, of II., I., and II.

Karsten unites *Cascarilla*, *Buena*, and *Remijia* with the genus *Cinchona* as a sub-genus. *Ladenbergia*, and groups nearly all true cinchonas in the sub-genus *Quinquina*, the two sub-genera being united by his sub-genus *Heterasca*, in which the capsules are dehiscent both from the base and apex, and which, among others, contains *Cin. micrantha*.

Collection and Commerce.—The great distance from populous districts at which the cinchonas are found renders it necessary to undertake expeditions of several months' duration. The *cascarilleros* (from *cascara*, the bark) are mostly Indians and half-breeds, a number of whom unite in gangs, each being under the direction of a magistral or mayor-domo and in the employ of speculators or of companies. Supplied with provisions, they undertake the journey over the mountains during the dry season, and locate their camp near a stream, where they frequently plant maize and beans as an additional supply of food during their protracted stay. A rude shed or hut is constructed in which the collected bark is dried, and the *cascarilleros* search for the trees, which they recognize either from the dry leaves and fruits on the ground or at a distance by their foliage and flowers. The trunk of the tree and the large roots just beneath the ground are then stripped of their bark, after it has been loosened by previously beating it with a mallet, by which in some cases (*Calisaya*) the corky layer is almost completely removed. The tree is then felled with an axe, and the climbing plants and adjacent trees which may support the cinchona are likewise cut, after which the peeling is completed and the bark carried, often for considerable distances, to the camp, where it is completely dried. The bark of the branches is simply exposed to the sun and rolled up into single or double tubes or quills, but the thick bark of the trunk, after some exposure, is often piled up in layers, crossing each other at right angles, and heavy weights are placed on the top. By this arrangement the curving or quilling of the pieces is prevented. In some places in New Granada the fresh bark is placed upon hurdles under a shed and dried by means of a fire made on the floor. (For further particulars see the interesting account of "A Visit to the Cinchona Forests of South America," by H. L. Wellcome, in *Proc. Amer. Phar. Assoc.*, 1879, pp. 814–830.)

After a superficial examination for the purpose of rejecting the bad bark, the remainder is assorted according to its size and made into bundles, which are sewn up in coarse canvas. These bundles, weighing about 150 pounds, are finally transported to the dépôts in the towns, where they are enclosed in fresh hides, which on drying contract and make a firm and compact package, the so-called *seroon*. Cinchona-bark is also frequently shipped packed in bales and in wooden boxes. The principal ports of exportation of the official barks are—for *Calisaya* bark, Arica, and to some extent Islay, in Peru; for the pale bark, Payta in Peru; and for the red bark, Guayaquil in Ecuador. Callao, on the

coast of Peru, the shipping-port of Lima, exports also considerable quantities of cinchona-bark. The Colombian (New Granada) barks are exported from Santa Marta and Savanilla, formerly also from Carthagena, and some bark collected in Venezuela is shipped from Puerto Cabello. During the years 1875–82 the average annual importation of all kinds of cinchona-barks into the United States was over 4,500,000 pounds.

For the collection of cinchona-barks in India several methods are in use. One, known as *mossing*, originally recommended by Karsten (*Deutsche Flora*, p. 1201), and introduced by MacIvor, consists in removing rather narrow longitudinal strips of the bark, and then covering the trunk with moss, when the bared portion will again become covered with bark, frequently richer in alkaloids than the unmossed bark. Another method is that of *coppicing*: the trees are cut down above the root and deprived of the bark, while the remaining stumps again produce shoots, from which bark may be collected after the lapse of about 8 years; a portion of the roots may then also be used for the collection of bark (*uprooting*). A third method is that of *shaving*, introduced by Moens in 1880, and consisting in the removal and collection of the outer layers, leaving a sufficiently thick layer of the inner bark to preserve the vitality of the tree. Shaved cinchonas have been attacked in Ceylon by a stag-beetle, a species of *Lucanus*, and mossed trees in Bengal have suffered from the destruction of the young bark by ants and other insects.

Commercial Terms.—The word *quina* (pronounced *gheena*) in the language of the Peruvian Indians signifies bark, and *quina-quina* a medicinal bark, the term being originally applied to other barks. It is equivalent to the Spanish *cascaquilla*, the diminutive of *casaca*, by which name the cinchona, with many other barks, is known in South America and in Spain. From the former word comes the French *quinquina* and the German *china*, by which terms the cinchona-barks are known in those countries. As the barks of different species are collected, they are in the first place distinguished as *quilled* or *flat* according to the manner in which they were dried; and, secondly, by some striking peculiarity, principally the color. The color of the external layer necessarily varies with the age of the bark and with the presence or absence of lichens and other cryptogamous plants. The fresh inner surface is always light-colored, but becomes darker on drying; it is always distinct in color from the natural surface, and in the bark of branches is invariably lighter than in the trunk-bark. The commercial terms used in this country are—at least for the unofficinal barks—almost altogether geographical ones, and refer to the town in which the *dépôt* was situated or to the port from which it was shipped. Lima, Huamalies, Huanuco, Jaen, etc. barks are sent from Peru; Loxa and Guayaquil barks, from Ecuador; and Bogota, Pitaya, Carthagena, etc. barks, from Colombia (New Granada). Since the cultivated cinchonas in India and other countries have commenced to yield valuable bark, this is now also frequently found in the market, and is, as a rule, distinguished by the botanical name of the species and the manner of production. (See below, under *Cultivation*.)

General Physical Description.—The shape of the commercial bark depends upon its treatment during the drying process, as described above. The South American quilled bark is usually much broken and quite irregular in size; the flat barks are rather more uniform, though their original size, about 18 inches (45 Cm.) in length and 4 inches (10 Cm.) in width, has mostly been considerably reduced through repacking and long transportation. These remarks apply also to the curved pieces of trunk-bark. But the cultivated bark is generally seen in rather uniform quills. The corky layer of the branch-bark, unless this is quite young, is usually more or less cracked. The surface of the bark of old wood is influenced in appearance by the presence or absence of the corky layer, which in some species is easily detached. The inner surface, if not torn, always presents a striate appearance, which is coarser or finer according to the relative thickness of the bast-fibres and their arrangement; the immature barks of very young branches have a slimy appearance upon the inner surface. The size, arrangement, and relative number of the bast-fibres impart to the transverse fracture its peculiar character, and the almost complete absence of these in younger barks causes them to break with a smooth fracture. The density of cinchona-barks varies considerably, but, according to Arnaud (1881), is in most cases less than that of water; Calisaya and Pitaya barks, however, are slightly heavier than water.

General Structural Characters.—The most important characteristics of cinchona-barks are due to their bast- or liber-fibres, which are never branched, are rather short, with their ends obtusely pointed, of a rather quadrangular appearance upon the transverse section under the microscope, showing the secondary deposits of the cell-walls.

by which the central cavity has been almost closed. They present some distinctions in their arrangement as seen upon the transverse section. In some species they are grouped together to the number of four to six, rarely more; in others they form single or double radial rows, four to ten in number; in others, notably in *Calisaya*, nearly every bast-cell is entirely distinct from the others, and is separately imbedded in the bast-parenchyma,

forming with the others not very regular interrupted lines. The medullary rays are distinct, but usually narrow; together with the preceding they form the *liber* (endophloem or inner bark). The liber is covered by the

primary layer (middle bark, mesophloem, cellular envelope, and green layer of authors) or *outer bark*, which consists of parenchyma; in some of the species (*C. Calisaya*, *succirubra*, *scrobiculata*, *officinalis*) one or two irregular rows of *laticiferous ducts* (or vessels—*lacunæ* of Pereira) are found just outside of the bast-rays; these ducts are thin-walled, rather short, not anastomosing, upon transverse section subcircular, and occasionally more or less filled with delicate cells, and they are observable even in old barks, unless the primary bark has been destroyed by secondary cork. Some species have in the primary bark laterally-elongated cells with thickened walls, either scattered or in groups; some of these *stone-cells* contain a brown mass of resinous aspect; others are filled with granular crystals containing calcium oxalate; hence they have been sometimes distinguished as *resin-cells* and *crystal-cells*. The epidermis is never present in the commercial bark; its place has been taken by a thinner or thicker *corky layer*, the primary cork (or *epiphloem*). In some species, like *Calisaya*, bands of thin-walled suberous tissue, or *secondary cork*, penetrate into the primary, and even into the bast-layer, of the bark, throwing off the outer tissues and remaining as the outer covering of the bark—Mohl's *rhytidoma*, the periderm of Wed-

Jell and others. The distinction between these tissues is neglected by some authors, but the formation of secondary cork evidently tends to obliterate characteristics observed in young barks.

General Chemical Characteristics.—All cinchona-barks contain astringent and alkaloidal principles, but they are present in very variable proportions. Grahe (1858) showed that if about 10 grains of the bark are heated in a test-tube characteristic red vapors are evolved, which condense in an oily carmine-red liquid. Cinchona-barks which have been deprived of their alkaloids by treatment with dilute acids do not show this reaction, but ligneous tissue which has been impregnated with a solution of cinchona alkaloids yields the sublimate; and the reliability of the reaction is increased, according to Hesse, by incorporating an alcoholic tincture of cinchona with powder of the same bark. This reaction, in connection with the presence of cinchona bast-fibres, noticed above, may be regarded as conclusive proof of the genuineness of cinchona-barks, in the absence of the peculiar bast-fibres, merely as evidence of the presence of cinchona alkaloids; for Flückiger (1871) observed a white bark which contained cinchona bast-fibres and an alkaloid (*paytine*), but yielded a brown tarry instead of a red oily sublimate; and the latter is obtained from *cuprea-bark* (see below), which contains cinchona alkaloids, but is destitute of cinchona bast-fibres.

Description of the Official Barks.—1. **CALISAYA BARK** is met with in quills and flat pieces. The quills are either single or double, and vary considerably in length, and between $\frac{1}{2}$ inch and 2 inches (1 and 5 Cm.) in diameter. The bark is from $\frac{1}{16}$ to $\frac{1}{8}$ inch (1.5 to 3 Mm.) thick, and covered with a grayish cork in which longitudinal and transverse fissures are observed. They are about 1 inch (25 Mm.) apart, and form irregular meshes with raised edges, frequently enclosing shorter transverse and oblique cracks. The corky layer is readily removed, leaving the impressions of the meshes upon the cinnamon-colored primary bark as lightly elevated lines corresponding to the deeper cracks. The inner surface is cinnamon-brown, darker than the primary layer, and finely striate from the bast-fibres. Occasionally quills are observed with the outer surface formed by a layer of secondary cork, which is brown, rather smooth, and has fine transverse fissures.

Flat Calisaya is met with in pieces occasionally 15 inches (38 Cm.) long, 3 to 5 inches (7 to 12 Cm.) broad, and from $\frac{1}{6}$ to $\frac{2}{3}$ inch (4 to 10 Mm.) thick. The external layer of secondary cork is very rarely present, except as small irregular dark-brown patches which line the shallow longitudinal depressions, the so-called *conchas* of the cascarrillos or *digital furrows* of Pereira and others. Otherwise, the entire bark consists only of bast-

FIG. 70.

Calisaya bark: showing digital furrow and short fibrous fracture.

layer, is of a bright-rusty cinnamon-brown color, and has the inner surface closely and uniformly marked with fine often wavy striæ.

The structural characteristics (see figs. 65, 66, 69) of the bark are found in the one or two rows of large laticiferous ducts outside the bast-layer, which are present only in young bark, in the almost total absence of stone-cells, and in the single bast-cells. Secondary cork is soon formed, and penetrates obliquely into the bast, thereby throwing off the primary bark and laticiferous ducts, and after its removal leaving the *conchas*. In the young and old bark the bast-fibres are, with occasional exceptions, singly imbedded in the bast-parenchyma, and show radially, and still more tangentially, an imperfect arrangement in rows. The disposition of the bast-fibres, their fineness and brittleness, permit them to be easily detached and to penetrate the skin on handling the flat bark; in the same way may likewise be explained the short, fibrous transverse frac-

FIG. 71.

Bark of Cinch. serobellata.

ture of the bark.

The flat Calisaya bark of commerce is often found mixed with flat pieces of the bark obtained from the variety *boliviana* (see *Origin*). It is distinguished by being thinner,

with the conchas more shallow and numerous, and by showing upon the longitudinal and transverse fracture large whitish spots. It agrees with the bark of the typical form in anatomical structure, but occasionally the secondary cork is found to penetrate the primary bark-layer only, leaving the laticiferous ducts present, and it has a portion of the bast-fibres arranged in but slightly interrupted radial lines; its transverse fracture is therefore more fibrous. Similar in physical appearance to *Calisaya* bark, but breaking with a long fibrous fracture, are the barks of *Cinch. scrobiculata* and *C. lancifolia*; they have for this reason been known as *fibrous Calisaya bark*. The tissue of both barks is of a reddish-yellow tint, and contains in the outer portion numerous large stone-cells. The *scrobiculata*-bark has the inner bast-fibres in nearly uninterrupted radial lines, and contains on the margin of the bast-layer a circle of laticiferous ducts. The *lancifolia*-bark has the bast-fibres in interrupted single or double radial lines, often forming groups, and accompanied by axially elongated but transversely narrow stone-cells, called *staff-cells*; laticiferous ducts are absent; the cork, if present, is soft and scaly, gray or whitish.

2. PALE CINCHONA.—*Loxa* bark is found in commerce in quills which vary very much in size and appearance. The thinnest bark has a nearly smooth and but slightly wrinkled surface; the older and somewhat thicker bark is marked by at first rather distant, finally more approximate, transverse sometimes annular fissures, and with longitudinal wrinkles or slight wart-like corky ridges. Aside from the variously-colored lichens, which are frequently present in patches, the external surface varies in color from dark brown-gray to blackish-brown, and the finely-striated inner surface between pale-brown and reddish-brown. The bark breaks with a smooth fracture, which is somewhat fibrous in the inner layers and of a light yellowish-brown color. The quills or double quills are usually much broken, though pieces a foot (30 Cm.) or more in length are sometimes met with.

In structure *Loxa* bark is characterized by thin laticiferous ducts, which are found only in very young bark, and by the arrangement of the bast-fibres in interrupted radial rows.

The bark of *Cinch. micrantha* has no laticiferous ducts, and the bast-fibres are either single or in scattered groups of two or three; the cork of the young bark is always of a brown-gray color, and has the transverse fissures less prominent.

3. RED CINCHONA-BARK is met with in quills and flat pieces. The former are often from $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) in diameter, with the bark about $\frac{1}{8}$ inch (3 Mm.) or less thick. The outer surface of even very young bark shows a somewhat netted arrangement, which becomes plainer in older bark, the long meshes being formed by confluent corky warts. The suberous layer is of a brown-gray color, and of a darker gray-brown to rust-brown in older barks; the inner layers and inner surface are of a cinnamon-brown, in thicker quills of a more or less deep red-brown or brown-red color. The bark breaks with a short fibrous fracture.

Cinch. succirubra: transverse section of bark; magnified 30 diameters.

The bark of old wood is termed flat, but is often in curved pieces 2 to 4 inches (5 to 10

Cm.) in width and $\frac{1}{2}$ inch (12 Mm.) or less in thickness. It shows the characteristics described, except that the bark throughout is of a deeper red color, the inner surface more closely striate, and the suberous layer thicker, very warty and firm, sometimes longitudinally fissured, more or less scaly, rather soft and spongy.

Its structural characteristics are a row of laticiferous ducts, and in the inner bast-layer narrow medullary rays and radially-arranged bast-fibres in interrupted lines.

Unofficial Cinchona-Barks.—A large number of commercial varieties have appeared in the market, made up frequently of the barks of different species, and therefore difficult to characterize. This difficulty is greater with the small quills, but even the old barks of botanical varieties of the same species often present considerable differences in their physical and histological characters. We shall give brief descriptions of the most important varieties:

PITAYA BARK is in flattish or curved pieces about $\frac{1}{4}$ inch (6 Mm.) thick, covered with a nearly

FIG. 73.

Bark of *Cinchona pubescens*.

smooth, soft, brownish ochre-colored cork, marked with nearly circular scars; the bast-layer is of a bright reddish-cinnamon color, and breaks with a short splintery fracture. The powder is of a brighter yellow tint than that of *Calisaya* bark. It is derived from *Cinch. pitayensis*, Weddell, and is valuable for the manufacture of quinine and quinidine.

CUSCO BARK comes, partly at least, from *Cinch. pubescens*, Vahl, and is in pieces similar to the preceding; but the corky layer is pale brown-yellow or whitish and warty, the bast-layer cinnamon-colored, and the fracture smooth on the outside and coarse splintery in the inner layer. Some varieties yield the alkaloid *aricine*. A red-colored variety of this species is called *China rubiginosa*.

CARTHAGENA BARK is in flat or usually curved pieces, occasionally in quills, with a pale ochre-yellow or whitish soft cork, often with somewhat glossy patches, internally of a dull-reddish or orange-cinnamon color, often interspersed with fine white dots of crystal cells; fracture, long or short fibrous. It is derived from *Cinch. lancifolia*, Mutis, the latter from *Cinch. cordifolia*, Mutis. The *China rubiginosa* of European writers is partly referred to a variety of the former species having a deeper red color. The bark is much used in the manufacture of quinine.

LIMA or HUANTCO BARK is generally a mixture of the quilled branch-barks of *Cinch. peruviana*, Howard, *C. nitida*, Ruiz et Pavon, and *C. micrantha*, Ruiz et Pavon, and perhaps of other species; the bark of the last mentioned is the most valuable of the three. The physical qualities must necessarily vary with the predominance of the different species. The same remark applies also to *Huamalies* bark, to which *Cinch. micrantha*, *glandulifera*, *purpurea*, Ruiz et Pavon, and other species contribute, and to the various *gray barks* of commerce.

The structural characteristics of cinchona-barks, as described above, vary in the different species, and may be briefly stated as follows:

1. Bast-fibres single, occasionally in groups of two, or rarely more:

C. CALISAYA.—No stone- (or resin-) cells, but laticiferous ducts in young bark. Secondary cork in old bark; bast-fibres of medium thickness; medullary rays narrow.

C. GLANDULIFERA.—Very few stone-cells; laticiferous ducts in one or two rows; bast-rays narrow; bast-fibres of medium thickness; medullary rays large celled.

2. Bast-fibres occasionally single, more frequently in groups of three or more:

C. MICRANTHA.—Few or no stone-cells; no laticiferous ducts; medullary rays narrow; bast-fibres of medium thickness, in groups of two and three, and in older barks of five to eight.

C. PURPUREA.—Numerous stone-cells; laticiferous ducts in one or two rows; medullary rays narrow and broadly wedge-shaped; bast-fibres of medium size, some larger, in groups of three to five, intermixed with some incomplete fibres.

C. PUBESCENS.—Stone-cells numerous; laticiferous ducts in one row; medullary rays rather broad; bast-fibres variable, large, in groups of two and three, intermixed with incomplete fibres or staff-cells.

3. Bast-fibres in interrupted single, or occasionally double, radial lines:

C. SUCCIRUBRA.—No stone-cells; laticiferous ducts in one row, in old bark often filled with cells; bast- and medullary rays narrow; bast-fibres medium, in lines of two to five, and occasionally eight.

C. OFFICINALIS.—No stone-cells; laticiferous ducts thin, soon obliterated; medullary rays narrow; bast-fibres medium, in somewhat irregular lines of two to four.

C. PITAYENSIS.—Few or no stone-cells; no laticiferous ducts; medullary rays with wedge-shaped opening; bast-fibres uniform, thin, in mostly single lines.

C. CORDIFOLIA.—Few stone-cells; no laticiferous ducts; medullary rays large celled; bast-rays narrow, the nearly uniform fibres in single or rarely double lines of two to four, with some incomplete fibres or staff-cells.

C. LANCIFOLIA.—Stone-cells numerous; laticiferous ducts none; medullary rays large celled; bast-rays rather narrow, the fibres medium and thicker, in single and double lines of two to four, intermixed with incomplete fibres (staff-cells).

C. NITIDA.—Few or no stone-cells; no laticiferous ducts; medullary rays narrow; bast-fibres thin, with numerous others of medium or thick size, in single, or some double, lines of two to four.

C. PERUVIANA.—Stone-cells present, small; laticiferous ducts small, in one row; bast-fibres small, varying, many incompletely filled, single or in double lines of two to six.

4. Bast-fibres in nearly uninterrupted radial lines:

C. SCROBICULATA.—Stone-cells numerous; laticiferous ducts in one or two rows; medullary rays large celled; bast-fibres very numerous, in but little interrupted single, or occasionally double, lines.

The structural peculiarities of cinchona-barks are, to some extent, influenced by the local conditions of growth, more particularly as regards exposure to or protection from the sunlight. This influence becomes more marked in the artificially-protected (*mossed*)

bark of the Eastern plantations, and still more in the second and third crops of (*renewed*) barks, in which the modifications of the parenchymatous tissue are very considerable, while the arrangement and characteristics of the bast-fibres are likewise subject to striking changes.

Allied Barks.—So-called *spurious cinchona-barks* are now rarely if ever met with in commerce. They were mostly obtained from trees belonging to the genera *Cascarilla*, *Ladenbergia*, *Nauclea*, and *Exostemma*; some of these are quite similar to cinchona-barks in appearance, while others have not the slightest resemblance to them. In those barks most nearly allied to the cinchona a cinchona bast-fibre is occasionally met with, but nearly all the bast-fibres have large central cavities. Others (*Nauclea*) have the thin fibres nearly filled up, but regularly arranged in radial and tangential rows. Grahe's test—and, more reliable still, the microscope—will at once prove their distinctiveness.

Spurious cinchona-barks—which, however, are very valuable for the manufacture of quinine—are the *cuprea* or *copper-colored barks*, a name given to them by Flückiger (1870) on account of their dull copper-red color. Samples of this bark were noticed in London in 1820, and occasionally it was observed as an admixture to the soft bark of *Cinchona lancifolia*; at the present time it is imported in large quantities, both from the central and southern parts of Colombia, along the eastern chain of the Andes. The bark from the former region was ascertained by Triana (1882) to be derived from *Remijia Purdieana*, Weddell, and R. (*Cinchona, Karsten*) *pedunculata, Triana*. It is in quills or curved pieces with a brown-red inner surface, externally with fragments of gray or brownish cork, and copper-red in the interior; the transverse fracture is coarsely granular, the longitudinal fracture rather splintery; the transverse fracture shows thick-walled cork-cells; sometimes scattered laticiferous ducts, many transversely elongated stone-cells, both in the outer bark and bast-layer, and in the latter numerous wavy medullary rays and radial lines of closely-packed, thin, elongated, obtuse bast-fibres, with the central cavity usually large; these bast-rays are less numerous in the inner than in the outer portion of the liber. The bark is very compact, hard, and heavier than water; that from Southern Colombia is denser, more compact, and shows a more horny fracture. Cuprea-bark varies considerably in the amount of alkaloids, which in bark from high elevations sometimes reaches 3 per cent. or 2 per cent. of quinine, the balance being quinidine and cinchonine; De Vrij (1882) obtained even 5.9 per cent. of alkaloids (Flückiger). Hesse first pointed out the entire absence of cinchonidine; and his observations have been confirmed by Howard and others. Cuprea-bark from Southern Colombia contains cinchonamine; Planchon (1882) found this bark to be free from laticiferous ducts and stone-cells, and the inner layer of the outer bark to be formed of laterally-elongated parenchyma.

Fraudulent red barks have been offered which had been made by exposing inferior cinchona-barks to ammonia, whereby cinchona-red is produced. Such barks were found by Thomas and Guignard (1882) to be deep-red in the parenchyma, to have pale-yellow bast-fibres, to yield red-colored infusions and decoctions, and these to give brown-red precipitates with Nessler's reagent, while the infusion of normal cinchonas gives a white precipitate with the same reagent; the chloroplatinate precipitate was found to contain 22 per cent. Pt. while that with the cinchona alkaloids contains only between 16.8 and 17.8 per cent. of this metal.

PINCKNEYA PUBENS, Michaux, s. Cinchona caroliniana, Biret, is a small tree growing in swampy localities from South Carolina to Florida. The bark is employed as a tonic and febrifuge under the name of *Georgia bark*. Dr. Farr claims having detected a considerable amount of cinchonine in the bark (Porcher, *Resources*, p. 442), which is probably incorrect, though the plant is likely to contain an alkaloid.

CROSSOPTERYX FEBRIFUGA, Bentham, s. Cross. Kotschyana, Fenzl, is a tree of tropical Africa having febrifuge properties, and, like the preceding, belonging to the sub-order Cinchoneæ. Hesse (1879) isolated from the bark .018 per cent. of an amorphous white alkaloid, *crossopteryne*, which is easily soluble in alcohol, ether, and ammonia, and yields bitter salts. The aqueous infusion of the bark shows blue fluorescence, which disappears on acidulation with sulphuric acid, and even after boiling reappears on the addition of an alkali.

Cinchona-Culture.—La Condamine (1738) noticed the reckless destruction of the cinchonas in South America, and after him most scientific men who had visited the cinchona region corroborated his statements. As early as 1792 the cultivation of cinchonas was suggested by Ruiz, and since 1837, Fritze, Blume, Miquel, and others advocated their transplantation to Java, while Royle (1839) pointed out certain districts in India as suitable for the cultivation of the plant. La Condamine's collection of living cinchonas and seeds was lost; Weddell (1848) procured considerable quantities of seeds, mostly of *C. Calisaya*, which germinated at the Jardin des Plantes in Paris, the seedlings being afterwards sent to Algeria and some to Java.

Weddell's *Histoire naturelle des Quinquinas* (1849) was the means of directing the attention of the Dutch government more prominently to this subject. Pahud, the colonial minister of Holland, selected Carl Hasskarl, previously director of the botanical garden at Buitenzorg, Java, who left Holland Dec. 4, 1852, to procure seeds and plants from Peru. His first collection of 50 plants remained through an oversight in Panama, and was afterwards returned to Lima, but the seeds reached Holland and yielded a number of seedlings,

which were sent to Java. A collection of 400 plants of *C. Calisaya* was transported amid many difficulties to the sea-coast, there packed in Wardian cases, and shipped Aug. 21, 1854, from Callao to Batavia, where, notwithstanding every care, only 46 plants arrived Dec. 13 in a good or partly sickly condition. They were planted a short distance from Batavia at an elevation of 4700 feet. In 1855, Junghuhn arrived there from Holland with 139 seedlings, nearly half of which perished, and when Hasskarl resigned in 1856 there were only 251 living cinchonas in the plantations. Junghuhn (died 1864) established plantations in more favorable localities, but ripe seeds were not obtained until 1858. Propagating from seeds and cuttings, there were toward the close of 1863 nearly 1,160,000 cinchonas in the plantations, not quite one-half of which number had been planted in the open air. Only 1.1 per cent. of the plants belonged to the more valuable species. The remaining one was Cinch. Pahudiana, *Howard*, a rapidly-growing species yielding a handsome-looking bark, which, however, contained but 0.2–0.7 per cent. of quinine, 0.8 cinchonidine, and a total of 1.4–1.8 per cent. of alkaloids. Since De Vrij had undertaken frequent assays of the barks of the different species grown under different conditions, the cultivation of the less valuable ones was abandoned by K. W. Van Gorkom, who succeeded Junghuhn, and by the close of 1876 nearly 2,000,000 cinchonas, not counting *C. Pahudiana*, were planted in the open air in the government plantations, and of this number 1,142,715 were *C. Calisaya* (including *C. Hasskarliana*). At present these plantations are in charge of J. C. B. Moens.

In the mean time, Boyle, Falconer, and others had again urged the introduction of the cinchonas into India, and, after several unsuccessful attempts to procure good plants and seeds through the British consuls on the west coast of South America, the British government decided in 1859 to organize an expedition under the direction of Clements Robert Markham, embracing all the districts of the most valuable species. Aided by John Weir, Markham explored the border-land of Peru and Bolivia, April and May, 1860, and collected 529 plants, 497 of which belonged to different varieties of *C. Calisaya*, the remainder to *C. ovata* and *C. micrantha*. 63 of this number perished during the transportation to the coast, 456 being shipped from Islay in Wardian cases June 24. Owing to the jealousies of the population and the obstacles raised by the Bolivian government, he was unable to return to the districts for the purpose of collecting seeds, which do not ripen before August. (See Markham's interesting work, *Peruvian Bark*, London, 1880.)

Richard Spruce undertook the collection of plants and seeds from the red bark districts (*C. succirubra*) in Ecuador, in the forests of Chimborazo, where he arrived in June, and was joined near the end of July by Robert Cross, who collected a large number of cuttings and young plants, and with these and the seeds gathered by Spruce embarked at Guayaquil Jan. 2, 1861. Plants and seeds in the neighborhood of Huanuco were collected by G. J. Pritchett, who embarked from Lima in Sept., 1860, mainly with specimens of *C. micrantha* and *nitida*. The government having neglected to provide for their direct transportation to India, the shipments were made by way of Panama to England, and thence through the Red Sea to Bombay. The plants, and particularly those collected by Markham, suffered considerably from various delays and from the hot weather encountered during a part of the journey; but those in charge of Cross mostly arrived in good condition, as also did the seeds collected by the explorers mentioned, and those obtained on a second journey undertaken by Cross in 1861 to the neighborhood of Loxa.

The first cinchona-plantation in India was established in the south-west, in the Neilgherry Mountains, near Ootacamund, at an elevation of 7000 feet. Under the care of William Graham McIvor (died 1876), who made many valuable observations on the cultivation of the different species, this was soon extended, so that in this district alone there were in 1866 over 1,500,000 cinchonas, besides those which had been distributed to or raised by private parties. While here *C. officinalis* appears to be the most valuable, *C. succirubra* and *Calisaya* succeed better in the Himalaya Mountains in Sikkim, where the cultivation was commenced in 1862. Plantations were also formed in Ceylon (1861), in Punjab (1864), and other portions of India. Since 1867 these barks have appeared in European commerce, and recently they are also met with in the United States. The packages of the Indian bark are always made up from the same species cultivated under the same circumstances, so that the *unmossed*, *mossed*, and *renewed* barks are never mixed. This distinction is due to McIvor, who proved that under an artificial covering of moss the bark of certain species becomes thicker and richer in alkaloids, and also that trees which have been partly peeled will under a covering of moss rapidly *renew* the bark.

Attempts at the cultivation of cinchonas have been made in many countries and islands, and have been partly abandoned. Of some importance is the experiment made in Jamaica,

where the plants were introduced late in 1861; the cultivation on a large scale, however, was not commenced until 1868, and under the care of Robert Thomson had in 1876 extended over 300 acres, the plantations being situated in the Blue Mountains at an elevation of from 4000 to 6000 feet, with a variation of temperature between about 50° and 70° F. The official species, *C. Calisaya*, *succirubra*, and *officinalis*, are mainly cultivated here, and since 1880 cinchona-bark has been sent into the market from Jamaica. The same species appear also to be cultivated to some extent near Cordova, Mexico, where seeds were distributed in 1866; at least, Hugo Finck exhibited (1876) handsome specimens of these barks and sections of the trees. The cultivation of cinchonas has been also commenced on a limited scale in Bolivia (Wellcome, *loc. cit.*, p. 828).

It is not unlikely that the cultivation of the above-mentioned valuable species of *Remijia* may be extended to many countries where the cinchonas cannot be profitably raised.

Constituents.—(1) **ALKALOIDS.** Cinchona-barks contain one or more of four alkaloids, which, according to their composition, form two groups—namely, *quinine* and *quinidine* = $C_{20}H_{24}N_2O_8$, and *cinchonine* and *cinchonidine* = $C_{19}H_{22}N_2O$. Gomes of Lisbon (1812) obtained a crystalline body without recognizing its chemical relations; its basic properties were discovered by Houton-Labillardière (1820), and Pelletier and Caventou found in its two alkaloids, which they named quinine and cinchonine. Henry and Delondre (1833) obtained from a red-colored bark a distinct alkaloid, which they named *quinidine*, and which constituted, most likely, the greater portion of Van Heijningen's *betaquinine*, obtained (1849) from chinoidine, and of the *cinchotine*, which Hlasiwetz (1850) found in the alcoholic mother-liquor of cinchonine. Quinidine is identical with the *conchinine* of Hesse (1869), but the latter considers Henry and Delondre's alkaloid to have been chiefly cinchonidine. F. L. Winckler (1847) separated from Maracaiibo bark an alkaloid which he likewise called *quinidine*, but which Pasteur (1853) proved to be distinct from the former and named *cinchonidine*. Pasteur's nomenclature has been adopted not only in France, but also in England and America; until recently several German writers, however, followed Winckler, and to some extent Hesse's nomenclature is employed in Germany.

Pasteur observed that by fusing the alkaloids of either group in the presence of acids they are converted into the amorphous bases *quinicine* and *cinchonicine*, which have the composition of the alkaloids from which they are obtained.

The bark of *C. succirubra*, cultivated in Sikkim, was found by Hesse (1872 and 1877) to contain also two other alkaloids, *quinamine*, $C_{19}H_{24}N_2O_2$, and *paricine*, $C_{16}H_{18}N_2O$. The latter is pale-yellow, amorphous, when fresh soluble in ether, and converted into a dark-green resinous mass by strong nitric acid. The same acid yields a dark-green solution with *aricine*, $C_{23}H_{36}N_2O_4$, discovered in Arica bark by Pelletier and Coriol (1829). It is crystallizable, and its oxalate and acetate are sparingly soluble. Winckler (1842) regarded it as identical with an alkaloid, *cusconine*, obtained by Leverkühn (1829) from Cusco bark, and with the *cinchovatine* of Manzini (1842), from Jaën bark, and the production of a green color by nitric acid due to the presence of impurities. But cusconine, though of the same composition as aricine and in the same bark, differs from all cinchona alkaloids in the gelatinous form of many of its salts, including the sulphate, which is not soluble in sulphuric acid. The same bark contains also the yellow amorphous alkaloid *cusconidine*, discovered by Hesse in 1877, and amorphous *cuscamidine* and crystalline *cuscamine*, discovered by the same chemist in 1880; the last two alkaloids are insoluble in nitric acid, cuscamine also in oxalic acid; both are readily soluble in ether, chloroform, and hot alcohol, and melt at 218° C. (424.4° F.). The *pitoyine* of Peretti (1835) does not exist, according to Kerner (1872) and Hesse (1873); it had been obtained from so-called Pitoya bark, or *Cinchona bicolorata*, the bark of a species of *Ladenbergia*, characterized by the gray and fawn-colored patches of its external surface.

Quinamine (chinamine), together with its isomer *conquinamine*, is found in the bark of *Cinch. succirubra*, *rosulenta*, and other species; both are crystalline, dextrogyre; their solutions are not fluorescent, do not produce thalleoquine, are precipitated by chloride of platinum only when in concentrated solutions, and yield with chloride of gold yellow precipitates changing to purple. Their hydriodates are slightly soluble in cold water and crystallizable. Quinamine melts at 172° C. (341.8° F.), conquinamine at 123° C. (253.4° F.). The former is dextrogyre, is soluble in 32 parts of ether, and on boiling with dilute sulphuric acid is converted into amorphous *quinamidine*, isomeric with the former and having a similar behavior to chloride of gold; its hydrochlorate crystallizes in prisms and is sparingly soluble in water. On heating sulphate of quinamine to 100° C. (212° F.)

it is converted into the isomeric *quinaminine*, which is white, amorphous, fusible in boiling water, and precipitated from acid solutions by sodium bicarbonate. When sulphate of quinamine, however, is heated to 120° C. (248° F.), *proto-quinaminine*, $C_{17}H_{20}N_2O$, is formed, which is insoluble in ether, and the sulphate of which is nearly insoluble in cold water. By treating quinamine or conquinamine with concentrated hydrochloric acid, H_2O is eliminated, and *apoquinamine*, $C_{19}H_{22}N_2O$, is formed, which is white, amorphous, very soluble in ether; its hydrochlorate is amorphous and freely soluble in water; the precipitate with chloride of gold does not turn purple.

The last-named alkaloid is isomeric with *homocinchonidine*, *homocinchonine*, and *homocinchonine*, the first of which forms the bulk of Winckler's *cinchoratine* (*aricine*), from Cinch. ovata, has a left rotation, and forms a sulphate crystallizing with $6H_2O$ in delicate needles of a gelatinous aspect which fuse near 30° C. (86° F.). It resembles magnesia when anhydrous, and in this condition forms with chloroform a jelly-like mass. On melting, the anhydrous monobasic sulphate of this alkaloid, homocinchonine, is formed. Homocinchonine is present in the bark of Cinch. rosulenta, which contains also *dihomocinchonine*, $C_{38}H_{44}N_4O_2$; it has a right rotation and is amorphous, like its salts.

Commercial cinchonidine sometimes contains the preceding alkaloids, and in addition thereto *hydrocinchonidine* or *cinchamidine*, $C_{19}H_{24}N_2O$, which was isolated (1881) by Hesse and by Forst and Boehringer; it melts near 230° C. (446° F.), is levogyre, and sparingly soluble in chloroform, ether, and water.

The same chemists have shown (1881, 1882) in commercial quinidine the presence of *hydroquinidine* or *hydroconchinine*, $C_{20}H_{26}N_2O_2$, which melts near 167° C. (332.6° F.), is dextrogyre, dissolves freely in hot alcohol and chloroform, and with some difficulty in ether, and yields fluorescent solutions and thalleioquine, like quinine. This base has been found by Hesse also in cuprea-bark.

Hesse (1882) isolated also from cuprea-bark *hydrocinchonine*, $C_{19}H_{24}N_2O$, which differs in some of its properties from Skraup's cinchotine (see CINCHONINÆ SULPHAS), and *hydroquinine*, $C_{20}H_{26}N_2O_2$, which melts at 168° C. (334.4° F.), is easily soluble in ether, and yields fluorescent solutions and thalleioquine, like quinine. The above hydro-bases are not oxidized by potassium permanganate in the cold.

Homoquinine, $C_{19}H_{22}N_2O_2$, was observed in cuprea-bark by Tod (1880), and further studied by Howard, Paul, Whiffen, and others. It melts at 177° C. (350.6° F.), is freely soluble in alcohol and chloroform, sparingly in ether, and shows fluorescence and thalleioquine reaction, like quinine. It is Whiffen's *ultraquinine*. Arnaud's *cinchonamine*, $C_{19}H_{24}N_2O$, discovered (1881) in a Colombian cinchona-bark, is soluble in ether, melts at 195° C. (383° F.), and yields crystallizable salts which, with the exception of the sulphate, are sparingly soluble in cold water and in diluted acids.

Diconchinine, $C_{30}H_{36}N_4O_3$, and *dicinchonine*, $C_{38}H_{44}N_4O_2$ are the principal constituents of *chinoidine*. (See CHINOIDINUM.)

The white cinchona-bark of Payta contains, according to Hesse (1870), crystallizable *paytine*, $C_{21}H_{24}N_2O + H_2O$, and amorphous *paytamine*, which resemble quinamine in their behavior to chloride of gold and solubility in ether, but differ in being levogyre and readily precipitated by chloride of platinum. This bark, however, has been ascertained by Hesse (1883) to come from a species of *Aspidosperma*.

Hesse (1877) obtained from a young Bolivian Calisaya bark a liquid alkaloid having a penetrating odor suggesting that of quinoline, and from Java Calisaya bark crystallizable *javanine*, which is very easily soluble in ether and dissolves in dilute sulphuric acid with an intense yellow color. From the mother-liquors of the preparation of quinine, Hesse (1882) obtained a volatile base, *cincholine*, as a pale-yellow oil, freely soluble in ether, alcohol, and chloroform, and nearly tasteless in neutral solutions. Flückiger (1883) suggests that it may have originated from the hydrocarbons used in the process. Howard's liquid alkaloid (1871) had the composition $C_{20}H_{24}N_2O_2$, and yielded thalleioquine and a crystallizable freely-soluble oxalate.

The relation of the cinchona alkaloids to each other in regard to their ultimate composition will be observed from the following:

$C_{23}H_{26}N_2O_4$: cusconine and aricine.

$C_{21}H_{24}N_2O$: paytine.

$C_{20}H_{26}N_2O_2$: hydroquinine, hydroquinidine (hydroconchinine).

$C_{20}H_{24}N_2O_2$: quinine, quinidine, quinicine, and $2(C_{20}H_{24}N_2O_2) - H_2O$: diconchinine.

$C_{19}H_{24}N_2O_2$: quinamine, conquinamine, quinamidine, and quinaminine.

$C_{19}H_{24}N_2O$: hydrocinchonine (cinchotine), hydrocinchonidine (cinchamidine), and cinchonamine.

$C_{19}H_{22}N_2O_2$: homoquinine, apoquinine.

$C_{19}H_{22}N_2O$: cinchonine, cinchonidine, cinchonine, apoquinamine, homocinchonine, homocinchonidine and homocinchonine, and $2(C_{19}H_{22}N_2O)$: dicinchonine.

$C_{17}H_{20}N_2O$: protoquinamine.

$C_{16}H_{18}N_2O$: paricine.

Not analyzed: euscoidine, euscamine, euscamidine, javanine, cincholine.

The characteristic properties of the four principal cinchona alkaloids may be compared as follows:

	QUININE.	QUINIDINE.	CINCHONINE.	CINCHONIDINE.
Rotary power,	Levogyre.	Dextrogyre.	Dextrogyre.	Levogyre.
Soluble in water,	167 parts.	2000 parts.	3740 parts.	1680 parts.
Soluble in 80 per cent. alcohol,	6 "	26 "	133 "	20 "
Soluble in ether,	23 "	30 "	371 "	76.4 "
Sulphuric acid solutions,	Are fluorescent, 1 in 200,000.		Not fluorescent.	
Chlorine-water and ammonia,	Emerald-green thalleioquine.		White precipitates.	
Chlorine-water, ferrocyanide of potassium, and ammonia,	Dark-red solutions.		No coloration.	
Anhydrous sulphate, soluble in chloroform,	1000 parts.	19.5 parts.	60 parts.	1000 parts.
Hydriodate,	More soluble than next.	Soluble in 1270 parts water, or 110 parts alcohol.	Readily soluble in chloroform, alcohol, ether, and water.	Slightly in water, readily in alcohol.
Iodosulphate,	Green in reflected, colorless in transmitted light; soluble in 1000 parts boiling water.	Similar to preceding, but different tint.	Purplish-black; in transmitted light yellow or reddish.	Purplish garnet-red; in transmitted light like preceding.

The iodosulphates are obtained by dissolving the sulphates in weak alcohol, acidulating with sulphuric acid, precipitating with tincture of iodine, and crystallizing the precipitate from alcohol.

A mixture of the more or less purified alkaloids obtained from red and other cinchona-barks has been used in India and other countries under the designation of *quinetum*, *cinchona febrifuge*, etc. In this country several secret preparations have been introduced under various names, consisting either wholly or chiefly of cinchonine or chinoidine.

Other Constituents.—The alkaloids are combined with one or more of the following acids: kinic, kinovic, and cinchotannic acids.

Kinic or *quinic acid* (*Chinasäure*), $C_7H_{12}O_6$, is found in cinchona-barks and in many plants of the natural orders Rubiaceae, Vaccinee, etc. The calcium salt was first prepared by De Legaraye (1745); the acid was recognized by Hermbstaedt (1785) as being organic, and supposed to be tartaric acid. But F. C. Hoffmann (1790) proved it to be distinct, and named it kinic acid. The investigations of Deschamps (1795), Vauquelin (1806), and others corroborated these results, and Liebig (1830) and others determined its composition. According to Hesse, it is not present in cuprea-bark. In the preparation of quinine it is contained in the filtrate from the precipitated alkaloids. It appears to be present to the amount of 5 to 7, or even 9, per cent., and when pure forms transparent colorless oblique rhombic prisms which fuse at 162° C., are readily soluble in water, less in strong alcohol, and slightly in ether. On treating it or one of its salts with manganese peroxide and sulphuric acid, it yields, besides carbonic and formic acids, a golden-yellow crystalline sublimate of *kinone* or *quinone*, $C_6H_4O_2$. On being heated with hydriodic acid it is converted into benzoic acid, and when fused with potassa it yields protocatechuic acid.

Kinovic or *quinovic acid*, $C_{24}H_{38}O_8$, is met with in the East Indian barks, and forms a tasteless shining crystalline powder which is insoluble in water and chloroform, slightly soluble in ether and cold alcohol, but soluble in alkalies and alkaline carbonates. It was discovered by Hlasiwetz (1859) as a product of the decomposition of kinovin.

Kinovin or *quinovin*, $C_{30}H_{48}O_8$, was discovered by Pelletier and Caventou (1821), and at first named *quinovic acid*, afterward *quinora bitter*: its glucoside nature was determined by Hlasiwetz (1859). It is an amorphous mass of a disagreeable bitter taste, sparingly soluble in cold water, soluble in ether, acetone, chloroform, fixed and volatile oils, and freely soluble in alcohol. Its compounds with the alkalies, lime, and magnesia are soluble in water. Its solution in alcohol, treated with hydrochloric acid gas, yields kinovic acid and uncrystallizable mannitan (kinovin sugar), $C_6H_{12}O_5$. It has been found in different cinchona-barks in quantities varying between 0.11 and 1.74 per cent., and is also contained in the barks of *Esenbeckia febrifuga* and *Buena magnifolia* (*China*, s. *Quina nova*, hence its name).

Cinchotannic (or *quinotannic*) acid appears to be present in the best cinchona-barks to the amount of 2 to 4 per cent. By treating the decoction with magnesia, precipitating the filtrate

with lead acetate, decomposing with sulphuretted hydrogen, and repeating this process, it is obtained as a pale-yellow mass of an acidulous and astringent taste, readily soluble in water, alcohol, and ether, turning greenish with salts of iron, and yielding cinchona-red with alkalies or on being boiled with water. According to Rembold (1867), by boiling with dilute sulphuric acid it is split into sugar and

Cinchona-red, $C_{28}H_{29}O_{14}$, which is nearly insoluble in water and ether, but dissolves readily in alkaline solutions and alcohol. It yields protocatechuic acid when treated with fusing potassa. Though contained in all cinchona-barks, those having a red color contain it in largest proportion—thick red bark over 10 per cent.

The odor of cinchona-barks is due to a minute quantity of a butyraceous *volatile oil*, which was first obtained by Fabbroni. Trommsdorff obtained 2 grains from 20 pounds of pale bark. The remaining constituents are of no importance either medicinally or pharmaceutically; they comprise starch, gum, sugar, resin, fat, wax, ammonium salts, and calcium oxalate, all in small quantities. Kerner's *cinchocerotin*, $C_{27}H_{48}O_2$, according to Helms (1883), appears to be related to betulin. The ash amounts to between 1 and 3 per cent., and consists mostly of the carbonates of calcium and potassium.

Variation of Alkaloids.—The *distribution* of the various constituents, and more especially of the alkaloids, is a matter of as great importance to the physician and pharmacist as to the manufacturer of quinine. It has been amply demonstrated that barks obtained from the same species grown in different localities, according to Karsten, even in their native forests, may vary greatly, not only in the total amount of the alkaloids contained therein, but likewise in the relative proportion of the alkaloids. Cultivated barks have been found to contain from 9 to 12 per cent. of alkaloids, and Cinch. Ledgeriana is often very rich in quinine, containing sometimes 13 per cent.; yet these same species yield frequently much smaller amounts. While there can be no doubt that this variation is caused by external influences, the proper course to be pursued in cultivation for increasing the percentage of alkaloids, of quinine in particular, has as yet not been discovered. Young barks are known to yield, as a rule, a smaller percentage of alkaloids than the bark of older wood, and attention has been directed to the frequently large yield from the root-bark. Investigations by D. Howard (1877) point to the general tendency of the root-barks obtained from different species of cinchona to augment very materially the amount of dextrogyrate alkaloids (quinidine and cinchonine), while the levogyrate alkaloids (quinine and cinchonidine) are produced in much smaller proportion. The bark of the root-fibres usually contains a still smaller percentage of these alkaloids.

That a certain protection is beneficial for the production of the alkaloids has been shown by experiments made in the East Indies. Howard (1871) demonstrated the presence of 9.75 per cent. of quinine (or a total of 11.40 per cent. of alkaloids) in bark from Cinch. officinalis, var. lanceolata, and Broughton (1870), a total of 13.5 with 9 per cent. of quinine. The variety pubescens, of the same species, yielded to Howard (1878) 12.90 per cent. of alkaloids, of which 6.94 was quinine and 4.48 cinchonidine. Indian red bark in quills often yields from 9 to 11 per cent. of alkaloids, one-sixth to one-third of which is quinine (De Vrij, 1873), and from the bark of C. officinalis, grown at Ootacamund, between 3.72 and 10.86 per cent. of alkaloids, one-fifth to two-thirds of which is quinine; the extraordinary yield of some of this bark has been referred to above.

The *wood* of the root and trunk contains kinovin, and occasionally about $\frac{1}{2}$ per cent. of alkaloids, according to Moens (1880). A minute amount of alkaloid has also been found by Broughton (1870) in the *leaves*, the bitter taste of which is mainly due to about 2 per cent. of kinovin; while Happersberger (1883) reports having obtained 0.5 per cent. of alkaloids from the leaves of C. officinalis, 1.5 per cent. from those of C. succirubra, and 2 per cent. from those of C. Calisaya. The bitter taste of the *flowers*, according to Broughton, is due to kinovin, and the *fruit*, which is likewise bitter, contains mere traces of alkaloid.

Valuation of Cinchona-Bark.—Cinchona should contain at least 3 per cent. of alkaloids; yellow cinchona and red cinchona, at least 2 per cent. of quinine.—*U. S.* Yellow cinchona should contain at least 2 per cent. of alkaloids soluble in ether; red cinchona, at least $1\frac{1}{2}$ per cent. of alkaloids soluble in chloroform.—*Br.* Cinchona should contain at least 3.5 per cent. of alkaloids soluble in ether.—*P. G.*

Process of U. S. P.—*L.* For total alkaloids: Cinchona, in No. 80 powder and fully dried at 100° C. (212° F.), 20 Gm.; lime 5 Gm.; diluted sulphuric acid, solution of soda, alcohol, distilled water, each a sufficient quantity. Make the lime into a milk with 50 Cem. of distilled water, thoroughly mix therewith the cinchona, and dry the mixture completely at a temperature not above 80° C. (176° F.). Digest the dried mixture with 200 Cem. of alcohol in a flask, near the temperature of boiling, for an hour. When cool, pour the mixture upon a filter of about 6

inches (15 Cm.) diameter. Rinse the flask and wash the filter with 200 Ccm. of alcohol, used in several portions, letting the filter drain after use of each portion. To the filtered liquid add enough diluted sulphuric acid to render the liquid acid to test-paper. Let any resulting precipitate (sulphate of calcium) subside; then decant the liquid, in portions, upon a very small filter, and wash the residue and filter with small portions of alcohol. Distil or evaporate the filtrate to expel all the alcohol, cool, pass through a small filter, and wash the latter with distilled water slightly acidulated with diluted sulphuric acid until the washings are no longer made turbid by solution of soda. To the filtered liquid, concentrated to the volume of about 50 Ccm., when nearly cool add enough solution of soda to render it strongly alkaline. Collect the precipitate on a wetted filter, let it drain, and wash it with small portions of distilled water (using as little as possible), until the washings give but a slight turbidity with test-solution of chloride of barium. Drain the filter by laying it upon blotting- or filter-papers until it is nearly dry. Detach the precipitate carefully from the filter and transfer it to a weighed capsule, wash the filter with distilled water acidulated with diluted sulphuric acid, make the filtrate alkaline by solution of soda, and, if a precipitate result, wash it on a very small filter, let it drain well, and transfer it to the capsule. Dry the contents of the latter at 100° C. (212° F.) to a constant weight, cool it in a desiccator, and weigh. The number of Gm. multiplied by 5 equals the percentage of total alkaloids in the cinchona.

11. For Quinine: To the total alkaloids from 20 Gm. of cinchona, previously weighed, add distilled water acidulated with diluted sulphuric acid, until the mixture remains for 10 or 15 minutes after digestion just distinctly acid to test-paper. Transfer to a weighed beaker, rinsing with distilled water, and adding of this enough to make the whole weigh seventy times the weight of the alkaloids. Add now, in drops, solution of soda, previously well diluted with distilled water, until the mixture is exactly neutral to test-paper. Digest at 60° C. (140° F.) for 5 minutes, then cool to 15° C. (59° F.), and maintain at this temperature for half an hour. If crystals do not appear in the glass vessel, the total alkaloids do not contain quinine in quantity over 8 per cent. of their weight (corresponding to 9 per cent. of sulphate of quinine, crystallized). If crystals appear in the mixture, pass the latter through a filter not larger than necessary, prepared by drying two filter-papers of 2 to 3½ inches (5 to 9 Cm.) diameter, trimming them to an equal weight, folding them separately, and placing one within the other, so as to make a plain filter fourfold on each side. When the liquid has drained away, wash the filter and contents with distilled water of a temperature of 15° C. (59° F.), added in small portions, until the entire filtered liquid weighs ninety times the weight of the alkaloids taken. Dry the filter, without separating its folds, at 60° C. (140° F.), to a constant weight; cool, and weigh the inner filter and contents, taking the outer filter for a counterweight. To the weight of effloresced sulphate of quinine so obtained add 11.5 per cent. of its amount (for water of crystallization), and add 0.22 per cent. of the weight of the entire filtered liquid (for solubility of the crystals at 15° C.). The sum in Gm. multiplied by 5 equals the percentage of crystallized sulphate of quinine, equivalent to the quinine in the cinchona.

Process of the Br. P.—Boil 100 grains of the bark, reduced to very fine powder, for a quarter of an hour in a fluidounce of distilled water acidulated with 10 minims of hydrochloric acid, and allow it to macerate for 24 hours. Transfer the whole to a small percolator, and after the fluid has ceased to drop add at intervals about 1½ ounces of similarly acidulated water, or until the fluid which passes through is free from color. Add to the percolated fluid solution of subacetate of lead until the whole of the coloring matter has been removed, taking care that the fluid remains acid in reaction. Filter and wash with a little distilled water. To the filtrate add about 35 grains of caustic potash, or as much as will cause the precipitate which is at first formed to be nearly redissolved, and afterward 6 fluidrachms of pure ether. Then shake briskly, and, having removed the ether, repeat the process twice with 3 fluidrachms of ether, or until a drop of the ether employed leaves on evaporation scarcely any perceptible residue. Lastly, evaporate the mixed ethereal solutions in a capsule. The residue, which consists of nearly pure quinia, when dry should weigh not less than 2 grains, and should be readily soluble in diluted sulphuric acid. The last requirement is for Calisaya bark. By the same process red bark should yield not less than 1.5 grains, and pale bark not less than 1 grain, of alkaloids.

Process of the P. G.—Agitate powdered cinchona, 20 Gm. with ammonia-water 10 Gm., alcohol 20 Gm., and ether 170 Gm., and macerate for a day; decant off the clear liquid 120 Gm., add to it 3 Ccm. normal hydrochloric acid; distil and evaporate the ether, and, if necessary, acidulate the residue with hydrochloric acid; filter, and, without heating, add 3.5 Ccm. normal potassa solution, and when the precipitate has subsided drop into the clear liquid potassa solution as long as a precipitate is produced; collect the precipitate upon a filter, and wash it repeatedly with small portions of water until the filtrate ceases to produce a precipitate on being dropped into a cold neutral saturated aqueous solution of quinine sulphate; drain the precipitate, press it between bibulous paper, and dry it first in the air, next over sulphuric acid, and finally in the water-bath, when it should weigh at least 0.42 Gm. If a small quantity be boiled with 300 parts of water, the liquid, filtered while hot, should on cooling separate floccules of quinine, and on adding to 5 parts of the clear cold liquid 1 part of chlorine-water, and afterward a little ammonia-water, a bright-green color should be produced.

De Vrij's Process (1873).—20 Gm. of powdered and sifted bark, dried at 100° C., are mixed with milk of lime containing 5 Gm. of slaked lime; the mixture is slowly dried, and then boiled with 200 Ccm. of strong alcohol; when cool the liquid is passed through a small filter; the residue, mixed with 100 Ccm. of alcohol, is then put upon the same filter and washed with

another 100 Ccm. of alcohol. The mixed filtrate is freed from calcium by a little sulphuric acid and the alcohol recovered by distillation; the residue, together with the alcohol and water used for washing the retort, is poured into a capsule and the alcohol carefully evaporated. The cooled solution is filtered to separate quinovic acid and fat, the filter washed with some acidulated water, the filtrate reduced by evaporation to about 50 Ccm., and while still warm precipitated by a slight excess of caustic soda. The precipitate is collected upon a filter, washed with the smallest possible amount of water, and the filter pressed between bibulous paper until the alkaloids can be readily removed. They are now transferred to a tared capsule, completely dried and weighed; the weight multiplied by 5 indicates the percentage of the mixed alkaloids. These alkaloids are powdered, treated with ten times their weight of ether, the undissolved portion is converted into neutral sulphates, and the solution, treated with iodide of potassium to separate the *quinidine*: from the filtrate *cinchonidine* is separated by tartrate of potassium and sodium, and after again filtering *cinchonine* is precipitated by soda. To determine the *quinine* the ethereal solution is evaporated, the residue dissolved in ten times its weight of weak alcohol sp. gr. 0.915, containing $\frac{2}{5}$ of its volume of dilute sulphuric acid, and the solution heated to about 50° C. (122° F.); tincture of iodine is added to produce iodosulphate of quinine, which is collected after cooling. The filtrate, if necessary, is slightly acidulated, warmed to expel the alcohol, and precipitated by potassa or soda, by which the *amorphous alkaloid*, including quinamine, is obtained.

Since none of the cinchona alkaloids are insoluble in ether, the process requires some modifications should a large amount of cinchonine be present; the mixed alkaloids left on evaporating the ethereal solution should then again be treated with a small quantity of ether. The weights as above ascertained are multiplied with 0.718 for quinidine, 0.804 for cinchonidine, and 0.565 for quinine—or, according to De Vrij, with 0.5509 for anhydrous quinine—to find the weights of the alkaloids named. Cinchonine and chinoidine are by the above process weighed directly as such. To determine from the mixed alkaloids merely the quinine, De Vrij (1875) proposed iodosulphate of chinoidine as a test solution.

Manufacturers of quinine generally prefer to ascertain by direct experiment the amount of sulphate of quinine obtainable.

Off. Prep.—1. Of Calisaya bark: Decoctum cinchonæ flavæ, *Br.*; Extr. cinchonæ, Extr. cinchonæ fluidum, Tinct. cinchonæ, *U. S.*; Extr. cinch. flavæ liquidum, Infusum cinchonæ flavæ, Quinæ sulphas, Tinctura cinchonæ flavæ, *Br.* 2. Of pale bark: Mistura ferri aromatica, Tinctura cinchonæ composita, *Br.* 3. Of red bark: Tinct. cinchonæ comp., *U. S.*

Medical Action and Uses.—The action and uses of cinchona will be more conveniently studied in connection with its several preparations, to the articles upon which the reader is referred.

CINCHONIDINÆ SULPHAS, *U. S.*—SULPHATE OF CINCHONIDINE.

Cinchonidinum sulfuricum.—*Cinchonidine sulphate*, *E.*; *Sulfate de cinchonidine*, *Fr.*; *Cinchonidin-Sulfat*, *Gr.*

Formula $(C_{19}H_{22}N_2O)_2H_2SO_4 \cdot 6H_2O$. Molecular weight 794.

The neutral sulphate of an alkaloid prepared from certain species of Cinchona, chiefly red bark.

Origin.—Certain cinchona-barks, notably those obtained from Cinch. succirubra, *Paron*, and Cinch. officinalis, *Hooker*, cultivated in India, and the South America barks from Cinch. lancifolia, *Matis*, and Cinch. tucujensis, *Karsten*, contain cinchonidine. A very similar alkaloid, called *homocinchonidine*, is rarely, and then only in minute quantities, found in these barks; but in certain lots of South American red barks the second alkaloid named is present in considerable proportion, wholly or partly replacing the former (Hesse, *Berichte*, 1881, p. 1890). These alkaloids were at first described by Winckler (1847) and others as *quinidine* or *chinidine*, a name which was retained for them long after Pasteur's investigations in 1853 (see CINCHONA, *Constituents*) by several chemists, and until recently by several manufacturers in Germany and Austria.

Preparation.—In the process of manufacturing quinine sulphate, and while recrystallizing this salt, mother-liquors are obtained containing mainly cinchonidine sulphate. On concentrating the solutions the salt crystallizes, and requires purification by recrystallization from water in order to obtain it free from quinine and quinidine sulphate. Formerly, it could be prepared from commercial chinoidine, which sometimes contained notable quantities of this alkaloid.

Properties.—Like the corresponding salts of the other cinchona alkaloids, cinchonidine sulphate is colorless, inodorous, very bitter, and has a neutral or faint alkaline reaction. It crystallizes from alcohol in handsome prisms containing $2H_2O$, but from water it may be obtained in two forms—either in colorless square glossy prisms, or in less lustrous fine and silky needles, the formation of either crystals depending upon both

the concentration and the quantity of the solution. The commercial salt resembles quinine sulphate in appearance. The anhydrous salt dissolves, according to Hesse, at 22° C. (71.6° F.) in 97.5 parts, and the crystallized salt in 67 parts (100 parts at 15° C., *U. S. P.*), of water; it is soluble in 71 parts of alcohol at 15° C. (59° F.), in 4 parts of boiling water, and in 12 parts of boiling alcohol (*U. S. P.*); it dissolves readily and freely in diluted acids, the solutions being free from fluorescence, is very sparingly soluble in ether and benzol, becomes gelatinous from the separation of its water of crystallization when immersed in chloroform, and dissolves in 1000 parts of that liquid at 15° C. (59° F.) and in 300 parts at 63.5° C. (146.3° F.), but more freely in chloroform containing alcohol. On exposure the salt effloresces, parting with $1\text{H}_2\text{O}$; at 100° C. (212° F.) it loses its water of crystallization, and in moist air absorbs again $2\text{H}_2\text{O}$; on ignition it is decomposed and volatilized, without leaving any residue. The aqueous solution yields with barium chloride a white precipitate insoluble in diluted hydrochloric acid; it is precipitated by potassio-mercuric iodide and other reagents for alkaloids, by neutral tartrates, and by ammonia. The latter precipitate dissolves in about seventy-five times its weight of ether, and requires about twelve times more ammonia-water for solution than the precipitate from a corresponding solution of quinine sulphate (Kerner, 1862). On mixing a drop of an aqueous solution of the salt with a drop of solution of potassium sulphocyanide, microscopic crystals are formed, which are either feathery and

FIG. 74.

FIG. 75.

Cinchonidine sulphate with KSeY: microscopic crystals.

stellately arranged around a centre, or are spike-like and united in star-like or fan-shaped groups. According to Hesse (1878), cinchonidine sulphate is so completely precipitated by an excess of potassium sulphocyanide that the filtrate is not rendered turbid by ammonia.

Homocinchonidine sulphate has the composition and properties described above, but crystallizes either in dull-white prisms or in delicate white needles, requires at 22° C. (71.6° F.) 69 parts of water for solution, and its aqueous solution, saturated at 50° C. (122° F.), congeals on cooling to a gelatinous mass consisting of delicate crystals and enclosing the mother-liquor, while under the same conditions the cinchonidine salt yields glossy needles, from which the mother-liquor may be readily drained. Both salts on being treated with potassium permanganate yield *cinchotenidine*, $\text{C}_{18}\text{H}_{20}\text{N}_2\text{O}_3$, which was discovered by Skraup (1879), crystallizes with $3\text{H}_2\text{O}$ in colorless prisms, melts at 256° C., and is not fluorescent in acid solutions (Hesse, 1881).

Tests.—The moderately dilute aqueous solution of the salt, acidulated with sulphuric acid, should not show more than a slight blue fluorescence (absence of more than traces of sulphate of quinine or of quinidine). The salt should not be colored by the addition of sulphuric acid (absence of foreign organic matters). If 1 Gm. be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.92 Gm. (water of crystallization = $3\text{H}_2\text{O}$). If 0.5 Gm. of the salt be digested with 20 Cem. of cold distilled water, 0.5 Gm. of tartrate of potassium and sodium added, the mixture macerated, with frequent agitation, for 1 hour at 15° C. (59° F.), then filtered, and a drop of water of ammonia added to the filtrate, not more than a slight turbidity should appear (absence of more than 0.5 per cent. of sulphate of cinchonine or of more than 1.5 per cent. of sulphate of quinidine).

Composition.—Pasteur (1853) gave to cinchonidine the formula $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}$; Skraup (1879) corrected it to $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}$, which has been verified by Hesse and Claus (1881), although the latter states that commercial cinchonidine occasionally corresponds better with

the first formula. Skraup and Claus regard homocinchonidine as slightly impure cinchonidine. Besides the differences given above, Hesse states that the alkaloid cinchonidine melts at 200° to 201° C. (392° to 393.8° F.), while homocinchonidine melts between 205° and 206° C. (401° and 402.8° F.). The sulphate crystallizes with 6H₂O, according to Goddefroy (1878), from hot concentrated solutions with 3H₂O. The formula given above requires 13.6 per cent., and for the salt with 3H₂O 7.3 per cent., of water of crystallization. The U. S. P. has adopted the formula (C₂₀H₂₁N₃O)₂·H₂SO₄·3H₂O (mol. weight 768), requiring 7.03 per cent., and for the salt with 6H₂O 13.13 per cent., of water of crystallization.

Physiological Action.—This salt, which has often been confounded with sulphate of quinidine, appears not to have been made a frequent subject of physiological investigation. According to Dr. Bockius, when given to the lower animals in poisonous doses it produces “intense congestion of the anterior portion of the cerebral hemispheres,” the same effect essentially that is caused by quinine. In a number of experiments made with this alkaloid Cerna found that “its effects are more or less similar to those produced by quinine,” but larger doses of it are required to produce the same results (*Phil. Med. Times*, x, 495). This conclusion has been confirmed by Sée and Rochefontaine. In regard to its action on man, it would seem to occasion less disturbance of the nervous system than quinine, less ringing in the ears, and less disturbance of vision, and vertigo. Like quinine, it reduces the febrile pulse. In a word, there does not appear to be any difference between the two alkaloids in their mode of action, but the intenser operation seems to belong to quinine. Laborde, however, pronounced it to be a convulsing poison.

Medical Uses.—Repeated and extended observation of the use of cinchonidine in the treatment of *intermittent fever*, *remittent fever*, and *malarial neuralgia*, made both in this country and in British India, proves conclusively it equal, or nearly equal, in efficacy to quinine in these diseases, both as a prophylactic and as a remedy. In *typhoid fever* it has been found to induce the same subsidence of the pulse as quinine, and its equal advantages as a tonic have been fully shown. It has seemed to be well borne where quinine could not be tolerated, and to be especially favorable in its action upon children. *Hydrobromide* of cinchonidine has been used in the summer complaint of children, in various malarial diseases, inflammations, and organic affections. The chief result of these experiments is, that it may be administered hypodermically without local irritation, and that it is a more efficient antipyretic agent than quinine in an equal dose (*Med. Record*, xviii, 10, 153). *Salicylate* of cinchonidine has been found useful by Prosser James “as a tonic and anti-periodic” in doses of from 5 to 10 grains (*British Med. Jour.*, 1881, i, 428).

The modes of administration of sulphate of cinchonidine are the same, in general, as are employed for sulphate of quinine, but it does not appear to have been given hypodermically. As an anti-periodic it should, like quinine, be prescribed in doses of from 10 to 20 grains (Gm. 0.60–1.30) 5 or 6 hours before the expected paroxysm. In mild cases 10 grains (Gm. 0.60) in divided doses may be given during the day.

CINCHONINA, U. S.—CINCHONINE, CINCHONIA.

Cinchoninum.—*Cinchonine*, Fr.; *Cinchonin*, G.

Formula C₁₉H₂₂N₂O. Molecular weight 294.

An alkaloid prepared from different species of *Cinchona*.

Origin.—This alkaloid was discovered by Pelletier and Caventou in 1820, and has been found in most cinchona-barks, in largest proportion in some of the pale cinchonas.

Preparation.—It is best prepared by precipitating the aqueous solution of cinchonine sulphate with ammonia-water, washing the precipitate with water until free from ammonium sulphate, and crystallizing from alcohol.

Properties.—Cinchonine is in transparent “white, somewhat lustrous prisms or needles, permanent in the air, odorless, at first nearly tasteless, but developing a bitter after-taste, and having an alkaline reaction; almost insoluble in cold or hot water, soluble in 110 parts (84.3 parts, Prunier, 1879) of alcohol at 15° C. (59° F.), in 28 parts of boiling alcohol, 371 parts of ether, 350 parts (101.6 parts, Prunier) of chloroform, and readily soluble in diluted acids, forming salts of a very bitter taste. At about 250° C. (482° F.) it melts and turns brown with partial sublimation. On ignition the alkaloid is dissipated

without leaving a residue."—*U. S.* Cinchonine is insoluble in ammonia and potassa, but dissolves in 108 parts of amylic alcohol, in warm fixed oils, volatile oils, benzol, and benzine. Its solutions are dextrogyrate; its acid solutions are not fluorescent, and do not give the thalleoquin reaction, but with chlorine-water and ammonia yield a white precipitate. Its alcoholic solution gives a yellow precipitate with picric acid which is insoluble in acids. The aqueous solutions of its salts are not precipitated by bicarbonates in the presence of tartaric acid, but yield precipitates with ammonia and other alkalies, their carbonates, with tannin, potassio-mercuric iodide, chloride of gold, chloride of platinum, phosphomolybdic acid, picric acid, and other reagents for alkaloids; also, by potassium ferrocyanide (Dollfus, 1848). This last reaction has been recommended by Dr. J. H. Bill (1858) as a test for cinchonine, the precipitate being insoluble in an excess of the precipitant and crystallizing from the hot mother-liquor on cooling in golden-yellow needles or scales. Seligsohn (1861) showed the presence of free acid to be necessary for obtaining these crystals, and that neutral solutions of cinchonine salts are merely rendered turbid or yield a resinous precipitate.

By the action of potassa on cinchonine Gerhardt (1842) obtained chinoline, and Greville Williams (1855, 1864) showed that in addition to this base the distillate also contained lepidine, cryptidine, and other bases. By long-continued boiling of its chloride with alcohol and potassa, Koenigs (1881) produced from cinchonine a crystallizable volatile base, *cinchene*, $C_{19}H_{20}N_2$. On oxidizing cinchonine or its salts by the action of lead dioxide and sulphuric acid, E. Marchand (1844) obtained *cinchotenine*, which is more readily obtained, according to Caventou and Willm, by the action of potassium permanganate, formic acid being formed at the same time. Cinchotenine, $C_{19}H_{20}N_2O_3$, by the further action of oxidizing agents yields Weidel's (1874) *cinchonic* (chinolin-carbonic acid), $C_{19}H_{17}NO_2$, *cinchomeronic*, $C_7H_5NO_4$, and other acids.

Tests.—A solution of the alkaloid in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of quinine or quinidine). On precipitating the alkaloid from this solution by water of ammonia it is very sparingly dissolved by the latter (difference from and absence of quinine), and requires at least 340 parts of ether for solution (difference from quinine, quinidine, and cinchonidine). It should not be colored, or but very slightly colored, by the addition of sulphuric acid (absence of foreign organic matters).—*U. S.*

Composition.—The formula given above is that of Laurent (1848). Pasteur's (1853) formula, $C_{20}H_{24}N_2O$ (mol. weight 308), has been adopted by the Pharmacopœia, but researches made since 1877 by Skraup and others prove the former to be correct. The alkaloid crystallizes anhydrous. As found in commerce, it contains a very similar alkaloid, which is not affected by cold potassium permanganate, is freely soluble in alcohol, yields a sulphate crystallizing in sharp needles, and is freed from cinchonine by fractional precipitation; Skraup proposed to call it *cinchotine*, and found it to be identical with Caventou's and Willm's *hydrocinchonine*, $C_{19}H_{24}N_2O$.

Derivative.—**CHINOLINA.**—Chinoline, quinoline. *El., Fr.*: Chinolin. *G.* Formula C_9H_7N . Mol. weight 129.—This base was obtained by Runge (1834) from coal-tar, and described as *leucol*. Gerhardt (1842) obtained it by distilling quinine or cinchonine with potassa. Greville Williams (1855) first prepared pure chinoline free from other bases. The purification by treatment with acids and fractional distillation is difficult, and the commercial article is usually a mixture. At present chinoline is cheaply and readily prepared by a patented process devised by Skraup; a mixture of aniline, nitrobenzol, glycerin, and sulphuric acid is heated, then diluted with water, and distilled to drive off nitrobenzol; on rendering the residue alkaline and distilling with steam, chinoline passes over. Chinoline is a colorless, mobile liquid, of the specific gravity 1.081 at 10° C. (50° F.), strongly refractive like carbon bisulphide, of a pungent somewhat bitter almond-like odor, and of a burning and bitter taste. It does not congeal at -20° , volatilizes at ordinary temperatures, boils at 238° C. (460.4° F.), and distils unchanged. It has an alkaline reaction, dissolves phosphorus, sulphur, arsenic, resin, and camphor, is sparingly soluble in water, and soluble in all proportions in alcohol, methyl alcohol, ether, aldehyd, fixed oils, volatile oils, and carbon bisulphide. Ignited, it burns with a bright sooty flame. On treating chinoline with amyl iodide and afterward with soda, crystals of *cyanin*, having a golden-green color and dyeing wool blue, are obtained: Williams found (1872) that the leucoline from coal-tar, treated in the same manner, did not yield an identical product. Chinoline—but not leucoline—yields a yellow crystalline precipitate with bichromate of potassium.

The salts of chinoline are inodorous when pure, mostly crystallizable, and precipitated by most reagents for alkaloids. *Chinoline tartrate* crystallizes in white permanent scales, and is more soluble in water than *chinoline salicylate*, which requires over 100 parts of water for solution. The salts with mineral acids are mostly deliquescent.

CINCHONINÆ SULPHAS, U. S.—SULPHATE OF CINCHONINE.

Cinchonia sulphas, U. S. 1870; *Cinchoninum sulfuricum*.—*Sulfate de cinchonine*, Fr.; *Schwefelsaures Cinchonin*, *Cinchoninsulfat*, G.

Formula $(C_{19}H_{22}N_2O)_2 \cdot H_2SO_4 \cdot 2H_2O$. Molecular weight 722.

Preparation.—The first mother-liquors obtained in the preparation of quinine sulphate are precipitated with soda, and the precipitate is washed first with water to free it from sodium sulphate, afterward with small quantities of cold alcohol, in which the other cinchona alkaloids are more readily soluble than cinchonine. The residue is then mixed with about eight times its weight of water, the mixture heated, and sulphuric acid is dropped in until a clear neutral solution is obtained, which is treated with animal charcoal, filtered while hot, and set aside to crystallize; the crystals are drained and dried.

Properties.—Sulphate of cinchonine crystallizes in hard, transparent and colorless, or semi-transparent and white clinorhombic prisms, which have a glassy lustre, are permanent in the air, inodorous, lose their (4.98 per cent.) water of crystallization at $100^\circ C.$ ($212^\circ F.$), fuse like wax at a somewhat higher temperature (at about $240^\circ C. = 464^\circ F.$, with partial sublimation, *U. S. P.*), then acquire a handsome red color, and finally burn, giving off a peculiar empyreumatic odor and leaving no residue. It is apt to form supersaturated solutions with water, of which it requires 14 parts to dissolve it at the boiling temperature; its solubility in cold water has been variously determined: 1 part of the salt was found to be soluble in 54 parts of water at $15^\circ C.$ (Kerner), in 65.5 parts (Hesse), and in 75 parts (Schwabe) at $13^\circ C.$ ($55.4^\circ F.$); these solutions have a neutral, or frequently a slight alkaline, reaction. The salt is very readily soluble in dilute acids, requires 1.5 of boiling and 5.8 parts of cold 80 per cent. alcohol for solution, dissolves in 60 parts of chloroform, readily in dilute acids, and is insoluble in ether, benzin, and benzol. Its solutions have a very bitter taste and are destitute of fluorescence. They yield a white precipitate with barium chloride (sulphate), are insoluble in dilute hydrochloric acid, and are precipitated by the reagents mentioned above, the precipitate by ammonia being so sparingly soluble in an excess that this reagent may be employed for the quantitative determination of the alkaloid. When a drop of a saturated aqueous solution of the salt is mixed with a drop of solution of potassium sulphocyanide, crystals will be formed which under the microscope will appear long, radiating, and considerably branched, resembling antlers or equisetum.

FIG. 76.

Cinchonine sulphate with KSeY: microscope crystals.

Composition.—The formula as given above is that of Laurent (1848), which has been adopted by most writers since Skrap's investigations (1877, 1879); it requires 82.8 per cent. of cinchonine. The Pharmacopœia has adopted Regnault's formula, $(C_{20}H_{22}N_2O)_2 \cdot H_2SO_4 \cdot 2H_2O$ (mol. weight 750), which requires 82.14 per cent. of cinchonine and 4.8 per cent. of water. Skrap found that by repeated fractional precipitation the commercial salt will yield *cinchotine*, $C_{19}H_{21}N_2O$, an alkaloid very similar to cinchonine, and identical with Caventou's and Willm's (1869) *hydrocinchonine*. It is more freely soluble in alcohol than cinchonine, yields a sulphate crystallizing in sharp needles, and is not affected by a cold solution of potassium permanganate.

Tests.—A moderately dilute solution of the salt acidulated with sulphuric acid should not show more than a faint blue fluorescence (absence of more than traces of sulphate of quinine or of quinidine). If 1 Gm. be dried at $100^\circ C.$ ($212^\circ F.$) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.952 Gm. If the salt, dried at a gentle heat, is macerated for half an hour, with frequent agitation, with seventy times its weight of chloroform at $15^\circ C.$ ($59^\circ F.$), it should wholly, or almost wholly, dissolve (any more than traces of sulphate of quinine or sulphate of cinchonidine remaining undissolved). It should not be colored by contact with sulphuric acid (absence of foreign organic matters).”—*U. S.*

Other Salts of Cinchonine.—ACID SULPHATE OF CINCHONINE— $C_{19}H_{22}N_2O \cdot H_2SO_4 \cdot 3H_2O$, mol. weight 446—obtained by dissolving the official sulphate in dilute sulphuric acid and crystallizing, forms octahedral crystals, which become opaque in dry air, and dissolve in about half their weight of water and in 90 parts of alcohol. They are insoluble in ether, and contain 5.92 per cent. of cinchonine.

HYDROCHLORATE OF CINCHONINE— $C_{19}H_{22}N_2O \cdot HCl \cdot 2H_2O$, mol. weight 366.4—made by treating an

excess of cinchonine with dilute hydrochloric acid, crystallizes in needles closely resembling sulphate of quinine, dissolves in 24 parts of water at 10° C. (50° F.), in 3.2 parts of boiling water, in 22.2 parts of chloroform, in 1.3 parts of 80 per cent. alcohol, and in 273 parts of ether spec. grav. .730, at 15° C. The salt melts above 130° C. (266° F.). It has been occasionally used for adulterating, or fraudulently sold for, sulphate of quinine, from which it is readily distinguished by the absence of fluorescence of its acidulated solution, by the white precipitate occasioned with silver nitrate, and by the sparing solubility in ether of the white precipitate with ammonia. It contains 80.24 per cent. of cinchonine.

Physiological Action and Medical Uses.—Sulphate of cinchonine is more poisonous to frogs and dogs than sulphate of quinine. The former in full doses does not so speedily produce buzzing in the ears and disordered vision, but, on the other hand, it is more apt to occasion a peculiar pain and sense of oppression in the frontal region of the head. It is also prone to excite præcordial pain, jerking of the tendons, muscular exhaustion, and faintness when freely used. Laborde, indeed, denies to this alkaloid and to cinchonidine an equality with quinia, alleging that they belong to the class of convulsing poisons (*Archives gén.*, Mar. 1880, p. 368).

Its therapeutical application is generally regarded as identical in nature with that of quinine, at least in the treatment of *periodical fevers*. But the certainty of its curative effects is by no means so well established. It has the advantage over quinine of being less bitter and much more soluble in water, as well as cheaper, but it has the disadvantage of being less reliable. The dose of sulphate of cinchonine is variously stated to be from one-third to twice as large as that of quinine.

Biach and Loimann (*Virchow's Archiv.*, lxxxvi. 456) performed experiments upon rabbits with the neutral tartrate of *chinolin*. The preparation had a very offensive smell and an acrid and burning taste. It was administered hypodermically in doses gradually increased from 1½ grains (Gm. 0.1), and was found to act promptly and decidedly in lowering the temperature, especially when the dose was large. After doses of gr. v to gr. viij (Gm. 0.3–0.5) the temperature fell to 90° F., and even lower, and the animal grew dull and numb and its reflex irritability declined. After doses of from gr. x to gr. xv (Gm. 0.60–1) general paralysis and collapse were followed by death. Donath (1882) states that 2 per cent. of tartrate of chinolin prevents lactic fermentation in milk, the decomposition of urine and gelatin, the development of bacteria, etc. Dr. Conrad Berens (*Inaug. Thesis*, Univ. of Penna., 1883) drew the following, among other conclusions, from a series of experiments with chinolin tartrate: It causes death by asphyxia; increases the force and frequency of the respirations, and then arrests the latter; it does not cause convulsions; it lessens, and finally abolishes, reflex action; it directly diminishes or abolishes muscular contractibility; it coagulates myosin and albumen, and causes an increased flow of saliva and bile, but does not act upon the spleen; it lowers blood-pressure by a direct action on the heart-muscle, as well as by paralyzing the vaso-motor centres; it lowers the temperature; and it is a powerful antiseptic.

As for the therapeutical value of this artificial product, of whose use the most important effects were predicted, the result, as usual, has not answered the anticipations. Like many other agents, it is an anti-pyretic, and must therefore be credited with sometimes interrupting the course of simple *intermittent fevers*. Brieger employed it without the slightest benefit in typhus, pneumonia, rheumatism, and remittent fever; in some cases it was vomited, and thereby reduced the temperature very slightly. In Philadelphia, Harrington found it valueless as an anti-periodic (*Phila. Med. Times*, xii. 392). It had also bad effects, such as disturbed digestion, vomiting, and nausea. The observations of Hiller, which extended to phthisis and typhoid fever, gave like results. He therefore abandoned its use (*Amer. Jour. of Med. Sci.*, July, 1882, p. 246). Seifert claims that a 5 per cent. solution of chinolin is an efficient solvent of *diphtherial* membranes; and Marcell makes a similar statement (*Centralbl. f. Ther.*, i. 540). Brieger pointed out anew that the similarity of composition of chinolin and quinine led physicians into the common error of concluding that the therapeutical action of the two were identical, but that when the former was subjected to the only legitimate test, clinical experience, it proved to be worthless as a medicine (*Zeitschrift f. klin. Med.*, iv. 296).

CINNAMOMUM, U. S.—CINNAMON.

Cannelle, Fr.; *Zimmt*, G.

The inner bark of the shoots of *Cinnamomum zeylanicum*, *Breyne*, s. *Laurus Cinnamomum*, *Linne* (Ceylon cinnamon), or of *Cinnamomum Cassia*, *Blume*, s. *Cinn. aromaticum*,

Nees, s. *Laurus Cassia*, *Aiton*, s. *Laur. Cinnamomum*, *Loureiro* (Chinese cinnamon). *Bentley* and *Trimen*, *Med. Plants*, 223, 224.

Nat. Ord.—*Lauraceæ*.

Official Kinds.—1. CINNAMOMI CORTEX, *Br.*; Cortex cinnamomi zeylanici, *Cinnamomum acutum*, s. *verum*.—Ceylon cinnamon, Cinnamon-bark, *E.*; Cannelle de Ceylon, *Fr.*; Zeylonzimmt, *G.*

2. CORTEX CINNAMOMI, *P. G.*; CORTEX CINNAMOMI CHINENSIS; Cortex cinnamomi cassiæ, *Cinnamomum chinense*, *Cassia cinnamomea*.—Chinese cinnamon, *Cassia*-bark, *Cassia lignea*, *E.*; Cannelle de Chine, *Fr.*; Zimmtkassie, Chinesischer (Gemeiner) Zimmt, *G.*

Origin.—The tree first mentioned above is variable in size, but usually of small stature, and is met with in forest districts of Ceylon, reaching an elevation of 3000 feet (920 M.). It has opposite coriaceous three- to five-nerved leaves, which are bright-green and glossy above and glaucous beneath; the small flowers are in terminal panicles, producing a somewhat fleshy ovoid fruit, which at the base is surrounded by the enlarged perianth. Not less than seven or eight well-marked varieties are distinguished, some of which are regarded by some botanists as distinct species.

The second species is likewise a small tree, 20 to 30 feet (6 to 9 M.) high, and has oblong elliptical three-nerved leaves, which when young are downy, like the petioles and young branches. The panicles are smaller; the flower and fruit resemble the preceding. It is indigenous to Southern China and Cochin China, and cultivated in Java.

Cinnamon was known and highly esteemed as a spice in the most remote times of history, but the kind first used appears to have been that derived from China, while Ceylon cinnamon is first mentioned about the year 1275. *Cinn. zeylanicum* is now cultivated in many tropical countries, without, however, producing a bark equal to that of Ceylon in the delicate aroma.

Collection.—Ceylon cinnamon, the cultivation of which is gradually declining through the extension of coffee-culture, is produced in the south-western part of that island, in the vicinity of Colombo, where the plants are pruned so as to cause them to form stools from which four or five shoots are raised for 18 months or 2 years, until the bark begins to turn brown by the production of a corky layer. The shoots, which are now about 8 feet (2.4 M.) high and 2 inches (5 Cm.) or less thick, are cut off and deprived of their leaves and thin portions, which are sold as *cinnamon chips*. The bark is cut transversely, either obliquely or in a straight line, at distances of about a foot, after which two or more longitudinal incisions are made and the strips of bark removed by inserting beneath it the peeling-knife called *mama*. The pieces are put one within the other, and the sticks thus formed tied together into bundles. After about 24 hours the external layers of the bark are carefully removed by placing each piece upon a suitable stick of wood and scraping with a knife. The small quills are then placed in the larger ones in such a manner as to form congeries of quills about 40 inches (1 M.) long. These sticks are kept 1 day in the shade, then dried in the sun, and finally made into bundles of about 30 pounds each. Cinnamon produced in Senegal, Brazil, and the West Indies is inferior in quality; that from Tellichery and Java comes nearest to Ceylon cinnamon.

The tree yielding Chinese cinnamon is extensively cultivated in the south-eastern provinces of China, occasionally with *Machilus velutina*, *Champ.*, also a lauraceous tree, the bark of which is used for obtaining a glutinous extract. With this exception only *Cinnamomum Cassia* is cultivated in the Chinese cinnamon-plantation, as was ascertained through personal observation by Charles Ford in 1882 (*Jour. Linn. Soc.*, Dec. 1882), who gives the following description of the collection of cinnamon: "When the trees are about 6 years old the first cut of bark is obtained. The season for barking commences in March and continues until the end of May, after which the natives say the bark loses its aroma, and is therefore not removed from the trees. The branches, which are about an inch thick, being cut to within a few inches of the ground, are carried to houses or sheds in the vicinity of the plantations. All the small twigs and leaves being cleared off, a large-bladed knife, with the cutting edge something like the end of a budding-knife, is used to make two longitudinal slits and three or four incisions, at 16 inches apart, round the circumference through the bark; the bark is then loosened by passing underneath it a kind of slightly-curved horn knife with the two edges slightly sharpened. Pieces of bark 16 inches long and half the circumference are thus obtained. The bark, after its removal and while it is still moist with sap, is then laid with the concave side downward, and a small plane passed over it and the epidermis removed. After this operation the bark is left to dry for about 24 hours, and then tied up in bundles about 18 inches in diameter, and sent into the merchants' houses in the market-towns."

Cinnamomum obtusifolium, *Nees*, and *Cinn. Burmanni*, *Blume*, appear to yield similar

products, but they are not cultivated, and their bark is probably rarely, if ever, found in the commercial article.

The U. S. Pharmacopœia recognizes the two kinds of "cinnamon under the title of *Cinnamomum*, the British Pharmacopœia only the Ceylon, and the German Pharmacopœia the Chinese cinnamon. The importation into the United States of Ceylon cinnamon has decreased from 20,600 pounds in 1877 to about 5000 to 10,000 annually, while little over 1,000,000 pounds of Chinese cinnamon were imported in 1877, against nearly 2,500,000 pounds in 1880.

Description.—CEYLON CINNAMON is in sticks about 40 inches (1 M.) long and nearly $\frac{1}{2}$ inch (12 Mm.) thick, formed of eight or ten layers of very thin bark, which are together spirally rolled up from both edges. The bark itself has the thickness of stout writing-paper, is brittle and splintery, and has the external surface of a dull light yellowish-brown, smooth, marked with faint longitudinal wavy lines of bast-bundles, and with a few scars or holes left by the leaf-stalks or branchlets. The inner surface is smooth, scarcely striate, and of a somewhat darker brown. The odor is fragrant, peculiar; the taste sweetish, aromatic, and pungent. Inferior kinds of cinnamon are usually somewhat thicker, darker in color, of less agreeable fragrance, and occasionally of a bitterish taste. Cayenne cinnamon has a reddish tinge and is quite mucilaginous. Java cinnamon is often very similar to Ceylon cinnamon in appearance, though hardly equal to it in flavor; sometimes it is of a darker color, resembling Chinese cinnamon, but thinner and of better flavor.

CHINESE CINNAMON, cinnamon cassia, or cassia-bark, comes loose or packed in bundles with bands of bamboo. The pieces vary considerably in length, and are either curved, double quilled, or in quills of $\frac{1}{4}$ to 1 inch (6 to 25 Mm.) in diameter. The bark is $\frac{1}{2}$ to $\frac{1}{3}$ inch (1 Mm.) or more thick, and has a smooth or finely-wrinkled reddish-brown outer surface, marked with some dark leaf-scars, occasionally with lighter-colored lines, and very generally covered with larger or smaller irregular patches of cork. It breaks with a short fracture, and when of good quality has a strong though less delicate cinnamon odor and taste.

Under the microscope Chinese cinnamon is seen to consist of the bast-layer only, the outer surface being formed by a continuous circle of stone-cells intermixed with bundles of bast-fibres; the narrow medullary rays separate the broad bast-wedges, consisting of regularly-arranged small groups or single bast-fibres and of bast-parenchyma, containing starch-granules and mucilage and scattered oil-cells. Chinese cinnamon, aside from the cork, consists of primary bark and of the bast-layer, in which the bast-fibres, groups of stone-cells, and oil-cells are scattered, and which contains more mucilage and starch than the preceding kind.

A kind of Chinese or *Saigon cinnamon*, of late occasionally met with, is in more regular unscrapped quills, yields a darker-colored powder, but has a very sweet and warm cinnamon taste. Its histological structure is very similar to Ceylon cinnamon.

The term *cassia lignea* is sometimes applied indiscriminately to Chinese cinnamon, or it is used only for the inferior varieties. Some writers have restricted it to a thicker bark, of a slight cinnamon odor and a mucilaginous, faint cinnamon taste. The origin of these barks is not positively known.

Constituents.—The two kinds of cinnamon agree in the main in their chemical constituents, the most important of which is volatile oil. (See *OLEUM CINNAMOMI*.) They also contain a considerable amount of tannin, some sugar, mannit, starch, and mucilage. Flückiger and Hanbury noticed that the infusion made with cold water

Cinnamon.

a, b, c, from China. d, e, from Ceylon.

becomes turbid on the addition of iodine or iodide of potassium, and the decoction of

both cinnamons discharges the color of a considerable quantity of iodine before it permanently assumes the blue color of iodide of starch. The body producing this reaction with iodine appears to be insoluble in alcohol and ether, but its nature has not been ascertained. A strong tincture of cinnamon gradually becomes gelatinous and loses its astringent taste.

Pharmaceutical Uses.—*SYRUPUS CINNAMOMI*, P. G. Macerate for 2 days cinnamon 10 parts, cinnamon-water 50 parts, and dissolve in 40 parts of the filtered infusion 60 parts of sugar.—*P. G.*

TINCTURA AROMATICA, P. G. Macerate Chinese cinnamon 5 parts, ginger 2 parts, cardamom, cloves, and galanga, each 1 part, in alcohol, sp. grav. 893, 50 parts.—*P. G.*

Off. Prep.—*Acidum sulphuricum aromat.*, *Aqua cinnamomi*, *Decoctum hæmatoxyli*, *Infusum catechu*, *Br.*; *Infusum digitalis*, *Pulvis aromaticus*, *U. S.*; *Pulv. catechu comp.*, *Pulv. cinnamomi comp.*, *Pulv. cretæ aromat.*, *Pulv. kiño comp.*, *Br.*; *Tinctura cardamomi comp.*, *Tinct. catechu comp.*, *Tinct. cinnamomi*, *Tinct. lavandulæ comp.*, *Vinum opii*, *U. S.*, *Br.*; *Tinct. rhei aromat.*, *U. S.*

Allied Products.—*CASSIA-BUDS*, *Flores cassiæ*, s. *Clavelli cinnamomi*, are the small, pedicellate, unripe fruits of one or more species of *Cinnamomum*; they bear some resemblance to cloves, but are smaller, and consist of the thick perianth, the six small lobes of which are folded over the depressed ovary. They have a cinnamon-like but less agreeable odor and taste, and contain a volatile oil and tannin. The average importation of cassia-buds into the United States is about 40,000 pounds annually.

The following barks, which resemble cinnamon in some respects, are similarly employed in their native countries and are occasionally met with in commerce:

CULILAWAN-BARK is obtained from *Cinn. Culilawan*, *Nees*, indigenous to the Moluccas. It is in flat or curved pieces $\frac{1}{10}$ to $\frac{1}{8}$ inch (2.5 to 6 Mm.) thick, grayish or brownish externally, dark cinnamon-brown internally, with the fracture corky and short fibrous. The odor resembles cinnamon with a mixture of cloves and sassafras; taste mucilaginous and aromatic.

CASSIA CARYOPHYLLATA, s. *Cortex caryophyllatus*, the clove-bark (*Nelkenzimmt*, *G.*), from *Dicypellium caryophyllatum*, *Nees*, of Brazil. It usually comes in quills $\frac{3}{4}$ to 1½ inches (2 to 4 Cm.) thick, and about 2 feet (60 Cm.) long, which are made up of from six to ten pieces of bark rolled up together. The bark is about $\frac{1}{16}$ inch (1.5 Mm.) thick, smooth or slightly wrinkled, chestnut-brown, often with a bluish tinge, fracture short, showing a whitish line near the outer margin; odor clove-like; taste mucilaginous, resembling cinnamon.

Medical Action and Uses.—The oil of cinnamon, like that of other aromatics, first stimulates, and then exhausts and depresses, the nervous system. Locally, it is a rubefacient and stimulant. The water and the oil of cinnamon are used to impart an agreeable flavor to medicines, and the former is associated with astringents in the treatment of *diarrhœa*. Cinnamon was anciently believed to stimulate the uterus, and recently has been used in conjunction with more powerful medicines, such as borax, ergot, cotton-root, etc., to promote *parturition* and to check *uterine hæmorrhage* after labor and during menstruation or depending upon disease of the womb. Powdered cinnamon may be prescribed in doses of from 10 to 30 grains (Gm. 0.60–2.00). An infusion may be made with a drachm (Gm. 4.0) of the bruised bark to half a pint of boiling water, and administered in doses of a tablespoonful or two every hour.

CLEMATIS.—VIRGIN'S BOWER.

Clematite, Fr.; *Waldrebe*, G.

The herb of different species of *Clematis*.

Nat. Ord.—*Ranunculacæ*, *Clematidæ*.

Description.—The genus consists of perennial herbs or woody vines climbing by the aid of the bending petioles of their opposite pinnate leaves. The flowers have four to six colored sepals, minute or no petals, numerous stamens, and many akenes, which are prolonged into a feathery or rarely naked tail, consisting of the permanent style. The following species have been used:

Clem. erecta, *Linné*, indigenous to Europe. The leaflets are five to nine in number, oblong, narrowed below or usually cordate at the base, acute, entire, pale-green beneath, three- to five-nerved. The white flowers are in cymose clusters. It was formerly known as *Herba flammulæ Jovis*.

Clem. Vitalba, *Linné*, indigenous to Europe. The leaflets are about five in number, ovate, heart-shaped at the base, acute, coarsely serrate or entire, three- to five-nerved, pubescent when young. The white flowers are in cymose clusters and have the sepals clothed with felt-like hairs.

Clem. Flammula, *Linné*, indigenous to Southern Europe. The leaves are twice pinnate, the leaflets small, varying between lanceolate and oblong, entire, but two- or three-lobed.

Clem. virginiana, *Linné*, common in Canada and the United States. Leaflets three, ovate, rounded or heart-shaped at base, lobed and cut-dentate, with mucronate teeth. Flowers white, in cymose panicles.

Clem. Viorna, *Linné*—*Leather flower*—indigenous to the Southern States. Leaflets three to seven, ovate, acute, smooth. Flowers single, nodding, with dark-purple leathery sepals.

Clem. cylindrica, *Sims*, resembles the preceding, but has single bell-shaped, bluish-purple flowers, with the sepals dilated and often crisped above.

Constituents.—The above species possess in the fresh state a very acrid taste, which is gradually lost. Braconot observed that the acrid principle may be distilled with water and is soluble in fixed oils.

Physiological Action.—All the numerous species of *Clematis* possess essentially the same properties, which are those of an acrid irritant. The juice or the bruised plant applied to the skin is apt to cause blisters, and even ulcers, and its emanations when it is crushed readily make the eyes water and inflame them. In Europe beggars avail themselves of these properties to produce ulcers upon their limbs for the purpose of exciting compassion. Hence, *clematis* is known as *beggar's-weed* (*l'herbe à gueux*). These irritant properties are very feeble in the dried plant. The American appear to be less acrid than the European species.

Medical Uses.—An infusion of the flowers and leaves of *clematis* has been used internally in chronic *rheumatism*, *syphilis*, *scrofula*, *dropsy*, and *quartan ague*. An infusion of the fresh buds of *C. vitalba* (gr. xv to gr. xl in water f3vi-vij) (Gm. 1.00–3.00, in water Gm. 200–250), with the addition of anise or other carminative, when taken in three doses at intervals of an hour, is said to act as an efficient hydragogue cathartic. The dried leaves in weak infusion have been used with advantage as a diuretic in some cases of *dropsy* following intermittent fever. In Europe the peasantry employ the fresh leaves as *vesicants*, and physicians have applied them in the same manner to relieve local *pains*, and also in chronic *rheumatism*, *gout*, and *paralysis*. Even in ancient times this plant was used in the substitutive treatment of chronic *skin diseases*, and much more recently an infusion of it in oil was employed to cure the *itch*. The affected parts, it is said, having been subjected to several frictions, became violently inflamed, but with the subsidence of the inflammation the itch was cured.

COCCUS, U. S., Br.—COCHINEAL.

Coccinella.—*Cochenille*, Fr., G.

The female insect, *Coccus cacti*, *Linné*.

Class Insecta; Order Hemiptera.

Origin and Collection.—The cochineal insect is indigenous to Mexico and Central America, and has been introduced into and is cultivated in some of the West Indian Islands, the Canaries, Algiers, and Southern Spain. It feeds on different species of cactus,

particularly on *Opuntia cochinillifera*, *Miller*, *O. ficus indica*, *Haworth*, *O. Hernandezii*, *De Candolle*, and others. The male insect is very small, has the rostrum or snout in the breast, two large wings, and the red body terminated by two long bristles. The female is nearly twice as large, is furnished with a rostrum, and has a bluish-red body, flattened below, convex above, wingless, and without terminal bristles; they attach themselves firmly to the plant, where they couple, after which they increase considerably in size and lay several thousand eggs; the insect then dies, and the body dries up, still enclosing the eggs, from which the young soon escape. During the rainy season in Mexico the insects are kept under cover upon cactus-branches, and when the weather begins to be

favorable they are *sown* upon the plants, and the young ones allowed to develop until the females become fecundated and enlarged, when they are brushed off from the branches, killed by dipping them into hot water, and afterward dried in the sun or near a fire. This process yields the black cochineal, while the silver-gray is obtained by killing and drying the insects by exposure to the hot sun or in suitable ovens. Some females are left upon the plants, and in this way three harvests are made before the rainy season again sets in.

Description.—Commercial cochineal is about $\frac{1}{8}$ inch (15 Mm.) long, nearly hemi-

FIG. 78.

Coccus cacti: female insect, natural size; *a*, before, and *b*, *c*, after, impregnation; *d*, dry, and soaked in water.

spherical, somewhat oblong and angular in outline, convex above, flat or concave on the lower side, transversely wrinkled, readily pulverizable, yielding a dark-red powder of a faint odor and slightly bitterish taste. Immersed in water, it imparts to it a red color, and swells up so that the ringed structure of the insect can be readily examined. There are two varieties met with in commerce—the *silver-gray* and the *black*. The former is of a purplish-gray, the latter of a purplish-black, color; it differs from the former in the absence from the furrows between the rings of the white wool which imparts to the other kind the gray color. Gray cochineal, when pure, contains a larger amount of coloring matter than the black variety, but has been often found adulterated; hence the latter was more esteemed, but is now also adulterated. An inferior kind, called *granilla* or *grana sylvestra*, consists of the uncultivated, mostly very small, insects, but is rarely seen in commerce. The United States import annually about 1,500,000 pounds of cochineal.

Adulterations.—Adulterated cochineal is not uncommon, the black being weighted with black lead, ferro-ferric oxide, or manganic binoxide, while the weight of the silver-gray variety is increased by barium or lead salts, talcum, and similar substances. The adulteration is now effected by exposing the cochineal to steam until the insects have attained their normal size without becoming wet, adding the powder, rotating the mixture in a drum, and finally drying by heat, when the adulterant will adhere between the wrinkles. Or an inferior quality of cochineal, moistened with warm water, is superficially colored by a mixture of barium sulphate or lead carbonate and ivory-black. Such frauds are readily detected by macerating some of the insects in water, when the powder is soaked off and the insect may be examined, or the cochineal is incinerated and the adulterant determined in the ash.

Facitious cochineal is said to have been occasionally met with, and to have been made of gums, starch, and various coloring and mineral matters.

A similar product is the *kermes*, *chermes*, or *alkermes*, which consists of the fully-developed females of *Coccus ilicis*, *Fabricius*, indigenous to the basin of the Mediterranean and living upon *Quercus coccifera*, *Linné*. By moistening with vinegar and drying in the sun they acquire a brown-red color. They are of the size of a pea, nearly globular, almost smooth, yield a carmine-colored powder, and produce with tin salt, like cochineal, a fine scarlet-red.

Constituents.—Besides fat, about 6 per cent. of moisture, a small amount of volatile acid, mucilaginous and glutinous compounds, cochineal contains *carminic acid*, $C_{17}H_{18}O_{10}$, which Belhomme believes to be also met with in the blossoms of *Monarda didyma*. It is readily soluble in water, alkalies, and alcohol, little in ether, and insoluble in the fixed and volatile oils. Its alcoholic solution is precipitated by alkalies, but the crimson color of its aqueous solution is succeeded by a purplish-red and precipitated on the addition of alkaline earth. Most metallic salts yield colored precipitates with it; the deposit with aluminium hydrate is called *lake*. On incineration pure cochineal leaves from .5 to .7 per cent. of ash. When decoctions of cochineal containing a little alum, cream of tartar, or salt of sorrel are set aside, they will deposit *carmine*, which in commerce is often found adulterated with starch and other substances; pure carmine should be entirely soluble in ammonia-water.

Off Prep.—Tinct. cardamomi comp., *U. S.*, *Br.*; Tinct. cinchonæ comp., Tinct. cocci, *Br.*

Medical Action and Uses.—It is very doubtful if cochineal possesses any medicinal virtues. It has indeed been reputed to be stimulant, anti-spasmodic, and diuretic, and cases are not wanting, especially of *whooping cough* and *neuralgia*, to prove its curative virtues. The beautiful carmine color which it imparts to various medicinal preparations is its only substantial title to a place in the Pharmacopœia.

COCHLEARIA.—SCURVY-GRASS.

Herba cochleariæ, P. G.—*Spoonwort*, *E.*; *Herbe au scorbut*, Fr.; *Löffelkraut*, G.

Cochlearia officinalis, *Linné*.

Nat. Ord.—Cruciferae, Siliculosae.

Description.—This biennial or annual herb is a native of Northern and Central Europe, where it grows in saline soil and is occasionally cultivated. The root is of the thickness of a quill, long and white. The numerous radical leaves are on long petioles, roundish heart-shaped, or almost reniform, very obtuse and nearly entire; those of the stem are ovate, obtuse, with few angular teeth, the lower ones petiolate, the upper ones clasping. The flowers are white, in terminal racemes, followed by globular ovate ascending pods, which are slightly flattened laterally, pointed by the persistent style, and con-

tain three to five red-brown seeds in each cell. All parts have a pungent, acrid, and bitterish taste.

Constituents.—Winckler obtained tannin and a bitter principle which, with myrosin of white mustard, yielded oil of mustard. O. Geiseler (1859) corroborated the statement that the volatile oil does not pre-exist, but is formed only on maceration with cold water; he found its spec. grav. to be 0.942 and its composition = $(C_8H_5)_2OS$. According to A. W. Hofmann, however, it is butyl-mustard oil, $CSN.C_4H_9$, or sulphocyanide of butyl, boils near $160^\circ C.$ ($320^\circ F.$), and yields with ammonia a crystalline compound fusing at $135^\circ C.$ ($275^\circ F.$). An oil obtained synthetically from butylamine had the composition of oil of scurvy-grass, but a different odor, and yielded an ammonia compound fusing at $90^\circ C.$ ($192^\circ F.$).

Pharmaceutical Uses.—SPIRITUS COCHLEARIE. P. G. Macerate 8 parts of bruised flowering scurvy-grass in 3 parts each of alcohol and water, and distil off 4 parts.

Allied Plants.—The following plants of the same natural order and sub-order have been more or less employed:

1. *CAPELLA* (Thlaspi, *Linné*) Bursa pastoris, *Moench*.—Shepherd's purse, *E.*: Bourse à pasteur, Molette, *Fr.*: Hirtentäschlein, *G.*—This annual is a native of Europe, but is extensively naturalized in most civilized countries. It has clustered, more or less deeply serrate or pinnatifid root-leaves, a stem about a foot (30 Cm.) or more high, with arrow-shaped sessile leaves and numerous small white flowers in terminal corymbs, which become much elongated. The fruit is a triangular obcordate pouch, which is laterally flattened, has a narrow partition, and contains numerous minute brown seeds. It flowers from early in spring to autumn, and has, particularly in summer, an acrid and bitter taste. Daubrawa (1854) found in the herb, besides the ordinary constituents of herbs, 6 per cent. of soft resin, a little sulphuretted volatile oil, and 9 per cent. of ash. The volatile oil obtained from the seeds was proven by F. Pless (1846) to be identical with oil of mustard. Mulder (1858) obtained from the seeds 28.8 per cent. of fixed oil and 26.5 per cent. of protein compounds.

2. *THLASPI ARVENSE*, *Linné*, and *Thl. campestris*, *Linné*.—Penny-cress, Mithridate mustard, *E.*: Thlaspi champêtre, *Fr.*: Bauernsenf, Feldkresse, *G.*—The small, compressed, roughish, brown seeds have an acrid alliaceous taste, and yield a volatile oil which Pless found to be a mixture of the oils of garlic and mustard.

3. *LEPIDIUM SATIVUM*, *Linné*.—Garden cress, Pepper-grass, *E.*: Cresson alénois, Cresson des jardins, *Fr.*: Gartenkresse, *G.*—This annual is indigenous to Western Asia, and is frequently cultivated for salad. The bitterish and slightly acrid herb and seeds, like those of *Lep. rudérale*, *Linné*, and *Lep. campestre*, *Linné*, contain myrosin, but, according to Pless, not myronic acid: they yield, however, a sulphuretted volatile oil which dissolves in sulphuric acid with a red color. *Lep. virginicum*, *Linné*, and *Lep. intermedium*, *Gray*, the wild pepper-grasses of North America, probably yield a similar volatile oil.

4. *LEPIDIUM IBERIS*, *Linné*.—Pepper-grass, *E.*: Passerage iberide, *Fr.*: Iberiskresse, Pfefferkraut, *G.*—This plant is found from Southern Europe to Siberia; has a branching stem about 2 feet high; petiolate, pinnatifid, or incisely serrate radical leaves about 2 inches (5 Cm.) long; smaller linear-lanceolate or linear entire somewhat grass-like stem-leaves, and minute white flowers in racemose cymes; the fruit is small, ovate, and acute. The plant is smooth and rather glaucous, and has a pungent taste, due to a sulphuretted volatile oil. Leroux (1837) obtained from the flowering-tops and seeds an amorphous bitter principle which he named *lepidin*.

The broad-leaved pepperwort, *Lepidium latifolium*, *Linné*, has similar properties.

5. *ANASTATICA HIEROCHUNTICA*, *Linné*, an annual plant of the Levant growing in dry, barren fields, is occasionally seen as a curiosity. After the seeds are ripe the branches become woody and curl inward, forming a kind of a ball, which when soaked in water unfolds like a flower: hence the popular name, *rose of Jericho*.

Medical Action and Uses.—Common scurvy-grass is stimulant, diuretic, and antiscorbutic, in virtue chiefly of its acrid essential oil. Its bitter principle also contributes to its medicinal qualities. When chewed it excites the secretion of saliva, and when swallowed a sense of warmth in the stomach; it also tends to relax the bowels. It is everywhere eaten as a salad, generally mixed with water-cresses, and has great popular reputation as a purifier of the blood. It is justly celebrated for its efficacy in *scurvy*, and is either eaten fresh, which is preferable, or its expressed juice is administered. It has also been used with reputed advantage in *scrofula*, *chronic intermittent fever*, and *dropsy* depending upon the latter disease. Externally, the bruised herb has been applied in poultices to stimulate scrofulous and other atonic ulcers; and the juice, diluted with water, has been used as a mouth-wash for *spongy gums* and ulcers of the mouth.

Shepherd's purse is astringent, acrid, and aromatic. The herb and the seeds were anciently employed as stimulants to promote *menstruation*, and more recently in *dysury*, *diarrhoea*, *dysentery*, and *intermittent fever*. It is also credited with hæmostatic powers in *menorrhagia*. It is administered in an infusion made with 1 ounce of the herb in 12

ounces of water (Gm. 32 to Gm. 400), reduced by heat to half a pint. 2 ounces may be given at a dose.

Iberis was known to the ancients, who employed it as a rubefacient in rheumatic and other local affections. Pliny ascribes the discovery of its virtues to a certain physician named Damocrates. Even in recent times its powdered seeds were incorporated in an ointment for purposes like those above mentioned. Internally, it is said to have acted as an irritant, producing nausea and diarrhœa, and to have been useful in *bronchitis*, *dropsy*, *gravel*, *squamous skin diseases*, and *intermittent fever*. Its value, if any, is not determined.

CODEINA, U. S.—CODEINE.

Codeinum, P. G.—*Codeia*, E.; *Codéine*, Fr.; *Codein*, *Kodein*, G.

Formula $C_{18}H_{21}NO_3 \cdot H_2O$. Molecular weight 317.

An alkaloid prepared from opium.

Origin.—Codeine is one of the constituents of opium, and was discovered by Robiquet in 1832. Grimaux (1881) succeeded in preparing it artificially by heating an alcoholic solution of morphine with soda and methyl iodide, thus showing that codeine is the methyl ether of morphine.

Preparation.—In preparing morphine by Gregory's process (see MORPHINA), after precipitating with calcium chloride the chlorides of morphine and codeine crystallize together, and on redissolving them in water and adding ammonia, morphine alone is precipitated. The ammoniacal filtrate is concentrated, the crystallizing codeine chloride freed from ammonium chloride, then dissolved in hot water, and decomposed by potassa, when a portion of the codeine will crystallize on cooling, but the greater part separate as an oily liquid, which gradually solidifies. The mother-liquor yields a further quantity of the same alkaloid, contaminated with some morphine. The alkaloid is washed with cold water, then dissolved in ether, the ethereal solution mixed with water, and evaporated to crystallize.

Properties.—Codeine is in "white or yellowish-white, more or less translucent, rhombic prisms, somewhat efflorescent in warm air, odorless, having a slightly bitter taste and an alkaline reaction, soluble in 80 parts of water at 15° C. (59° F.) and in 17 parts of boiling water, very soluble in alcohol and in chloroform; also soluble in 6 parts of ether and in 10 parts of benzol, but almost insoluble in benzin. When heated to 120° C. (248° F.) codeine loses its water of crystallization. At about 150° C. (302° F.) it melts, and on ignition it is completely dissipated. Codeine is dissolved by sulphuric acid containing 1 per cent. of molybdate of sodium (*Fröhde's reagent*) to a liquid having at first a dirty-green color, which after a while becomes pure blue, and gradually fades within a few hours to pale-yellow. On dissolving codeine in sulphuric acid a colorless liquid results, which on the addition of a trace of ferric chloride and gentle warming becomes deep-blue.

An aqueous solution of codeine added to test solution of mercuric chloride should produce no precipitate, and if codeine be added to nitric acid sp. gr. 1.200 it will dissolve to a yellow liquid which should not become red (difference from and absence of morphine)."—*U. S.* Codeine crystallizes readily from its solutions, the crystals, frequently rhombic octahedrons, being of considerable size when slowly formed. They melt when placed in boiling water, and form transparent oily drops before dissolving. In addition to the solvents mentioned above, the alkaloid dissolves freely in amylie alcohol, methylic alcohol, and carbon bisulphide, and in about 85 parts of ammonia-water, but is nearly insoluble in potassa and soda. Its aqueous solution produces precipitates in solutions of the salts of iron, copper, lead, and other metals. Codeine does not separate iodine from iodic acid, and is not colored blue by ferric chloride (difference from morphine). Its solution in absolutely pure sulphuric acid remains colorless for several days, but on heating to 150° C. (302° F.) becomes brown-green, and after cooling reddish; in the presence of traces of nitric acid or of iron the cold solution gradually changes to green and blue, and deposits a blue precipitate. *Erdmann's reagent*, used for this test, consists of 20 Gm. of pure sulphuric acid and 10 drops of a mixture made with 6 drops of nitric acid spec. grav. 1.25 and 100 Gm. of water. For the testing of alkaloids *Fröhde's reagent* is best prepared by adding 1 Mg. of sodium molybdate to 1 Ccm. of pure sulphuric acid. The yellow solution of codeine in nitric acid when heated contains *nitrocodeine*, $C_{18}H_{20}(NO_2)NO_3$. Codeine yields with chlorine-water a colorless solution, which changes to red-brown on the addition of ammonia.

Physiological Action.—The action of codeine upon animals seems to vary with

its dose and mode of administration. 1 grain given to a rabbit hypodermically produced fatal tetanus, while 10 grains in the stomach of a similar animal occasioned only a peaceful and prolonged sleep, from which, however, it was easily aroused. By the former method it was more speedily fatal to these animals than an equal dose of morphia. On their awaking they were neither paralyzed nor dull. It has also induced tetanus in dogs. Given to man in the dose of $1\frac{1}{2}$ grains, it may create marked gastric disturbance, congestion of the head, dulness of the mind, and tremor; but in the dose of $\frac{1}{4}$ grain it usually produces calm and refreshing sleep, and does not cause sweating, eruptions on the skin, nausea, vomiting, or constipation. In the case of a child affected with diabetes and albuminuria it occasioned an inert and drowsy condition (*St. Bart's Hosp. Rep.*, xv. 224).

Medical Uses.—Codeine has been chiefly employed to allay *restlessness, cough*, and other symptoms for which opium is generally prescribed and when the latter medicine is not tolerated. In *phthisis* it seems to appease the cough without deranging the digestion. In like manner, it has been found to lessen the irritability of the stomach in cancer of that organ. But it is chiefly in *diabetes* that it has been recommended, especially upon the ground that it does not produce the narcotic effects of opium or morphine (*Edinb. Med. Jour.*, xvii. 461). But it is well known that in that disease narcotism is not produced by those remedies. There is no doubt that under the use of codeine and an appropriate regimen diabetes may be greatly benefited in some instances, but in quite as many it entirely fails. Its power of diminishing the urine and its saccharine contents is sometimes marked (*St. George's Hosp. Rep.*, ix. 679). This alkaloid has been used as an anodyne and antispasmodic in several diseases attended with paroxysmal *pain* or disordered *muscular action*. It is represented by some to be comparable to morphine in its effects when given in a little more than twice the dose, but others declare that its proper hypnotic dose is many times larger than that of morphine. A quarter of a grain may be prescribed, to be repeated if necessary. In a case of diabetes, above referred to, the daily dose varied from 10 to 15 grains. The muriate and the sulphate of codeine may be given in similar doses. One-sixth of a grain has often been administered hypodermically. A phosphate of codeine has been prepared whose solubility and unirritating quality adapt it to hypodermic use. Its dose is said to be about double that of the morphine salts.

COLCHICUM, U. S., Br., P. G.—COLCHICUM.

Meadow-saffron, E.; *Colchique*, *Safran bâtard*, Fr.; *Herbstzeitlose*, *Wiesensafran*, G.

The tuber and seeds of *Colchicum autumnale*, Linné. Bentley and Trimen. *Med. Plants*, 287.

Nat. Ord.—Melanthaceæ.

Official Parts.—1. COLCHICI RADIX, U. S.; Colchici cormus, Br.; Bulbus, s. Tuber colchici.—Colchicum-root or corm, E.; Bulbe de colchique, Fr.; Zeitlosenknollen, G.

The tuber (corm).

2. COLCHICI SEMEN, U. S.; Colchici semina, Br.; Semen colchici, P. G.—Colchicum-seed, E.; Semences de colchique, Fr.; Zeitlosensamen, G.

The seeds.

Origin.—The plant is indigenous to Europe, in the southern and central parts of which it is frequently found in pastures and meadows, flowering in September or October and ripening its seeds in June following. In the autumn the subterranean portion consists of the fully-developed tuber (corm of many writers), bearing at its apex the scar left by the fruit-stem of the preceding summer. A tuft of root-fibres is attached to a lateral projection of the base, above which there is a shallow groove running to the apex of the tuber. In the lower part is a short conical axis with three or four rudimentary leaves, and bearing upon the apex one or more flowers, with the lower part of their long perianth-tubes resting in the groove. The whole is surrounded by a few brown leaves, forming a sheath above. After flowering the tuber gradually diminishes in size, until by the following summer it is completely absorbed and decayed. In the mean time the upper internode of the short conical axis is gradually developed into a stem rising above ground with the capsules, and at the base is enlarged to an ovoid fleshy tuber, as yet without the lateral groove, but showing in the lower axil the bud, which by the following autumn will be developed into a short conical flowering axis, while in the mean time the lateral groove on the fruit-bearing tuber will have been formed. The development and duration of the tuber embrace, accordingly, a period of 2 years, in the first half of which

the tuber produces flowers and fruit, and afterward serves for developing and nourishing its successor.

The flowers resemble those of *Crocus*, have a whitish tube about 5 inches (12.5 Cm.) long, and a six-parted pale lilac or rose-colored border. The ovary remains underground during the winter, and is afterward formed into an obtusely-triangular, oblong-ovate, and inflated capsule, which is three-celled, bears the numerous seeds in the centre, and is surrounded by four or five linear lanceolate leaves. The tubers are collected in July and August, before the appearance of the flowers; but Schroff (1856), and afterward MacLagan, concluded from physiological experiments the proper time for the collection to be the period of flowering and immediately afterward.

Description.—1. **THE TUBER.** It preserves its properties best if dried entire by exposure to the sun and air, and is then of an ovoid shape, 1 to 1½ inches (25 to 38 Mm.) long, and nearly as thick at the thickest portion, convex on one side, flattened and with a

FIG. 79.

Tuber of Colchicum.

FIG. 80.

Colchicum: transverse section.

groove on the other. After the removal of the brown membranous teguments the surface is of a brownish or ash color, longitudinally wrinkled and internally white. In our commerce it is usually met with in transverse slices about ½ inch (3 Mm.) in thickness, somewhat reniform in shape, and notched on one side, of a white mealy appearance and breaking with a short and mealy fracture. In the fresh state it has a radish-like odor, which is completely lost on drying. The taste is sweetish, then bitter and somewhat acrid. The tissue is formed of regular parenchyma, filled with more or less angular, mostly compound starch-granules, and of rather delicate scattered fibro-vascular bundles with spiral ducts. Colchicum-tubers exhibiting a blackish color upon the recent fracture should be rejected. From the investigations of T. F. Beckert (1877), however, it appears that the amount of colchicine is scarcely influenced by the color, but decreases in old colchicum-root.

The Oriental *hermodactyls* resemble this tuber, but have a smooth surface, and vary in color between whitish and blackish, and in taste between insipid and bitter. They have been referred to *Colch. variegatum*, *Linné*, which is found in Southern Europe and Asia Minor, but are probably obtained from different species indigenous to Asia. Orphanides (1875) enumerates not less than forty-three distinct species.

2. **THE SEEDS.** They are about ⅓ inch (2 Mm.) in diameter, nearly spherical, slightly pointed at the hilum by a crest-like appendage, of a dull-brown color, finely pitted, somewhat glutinous when fresh, and with a powdery surface when older. They are entirely inodorous, and have a bitter, acrid taste. The finely-punctate testa adheres closely to the whitish thick horny albumen, which renders the seeds very difficult to powder, and encloses a very small embryo nearly opposite the hilum.

The powdering is effected by grinding them in a mill with hardened plates; or if done in a mortar they should be well dried, or else previously soaked in the menstruum to be used for exhaustion, and while still moist crushed beneath the pestle in small quantities. Rosenwasser (1877) proved that unbroken colchicum-seeds yield to solvents less than one-third the amount of colchicine contained in them; Hübler's observation, that warm solvents extract all the active principle from the unbroken seed, was corroborated by L. I. Morris (1881) and by Hertel.

Constituents.—The important constituent of the tuber, flowers, and seeds of colchicum is *colchicine*, according to Hübler (1864) of the formula $C_{17}H_{19}NO_5$, and by acids converted into *colchicein*. Pelletier and Caventou (1820) supposed it to be veratrine, but Geiger and Hesse (1833) proved it to be distinct. Owing to a case of poisoning by wine of colchicum which occurred in Berlin in 1855, it again attracted attention, and was examined (1857) by Aschoff, Bley, John E. Carter, and others. Oberlin (1856) denied

FIG. 81.

Colchicum-seed: a, natural size; b, section magnified.

the alkaloidal nature of this body, and regarded (1857) the crystalline *colchicine* as the poisonous principle of colchicum. The majority of investigators, including Ludwig (1862), Diehl (1867), and Hertel (1881), regarded it as a nitrogenated non-alkaloidal bitter principle, which is readily altered by chemical reagents, though it is not a glucoside, as was asserted by Walz. But Carter's colchicine (a specimen of which is in the cabinet of the Philadelphia College of Pharmacy) is unmistakably though feebly alkaline, as we have shown in 1867; it affords also precipitates with the usual reagents for alkaloids. Similar results were obtained by Eberbach (1874), who succeeded in crystallizing it from chloroform in silky needles. Rosenwasser (1877) obtained crystals from benzol, which became amorphous after exposure to the air for several months. According to Hertel, colchicine prepared in the usual manner contains fruit-sugar and other impurities, notably two resins, and also colchicein; these principles are thus characterized: *Colchicine*, $C_{17}H_{23}NO_6$, is colorless or yellow, amorphous, soluble in water, alcohol and chloroform, less soluble in ether, of a saffron-like odor and bitter taste, precipitated by tannin, turns moist litmus-paper slowly blue in consequence of incipient decomposition, with formation of ammonia, and its aqueous solution is colored yellow by hydrochloric acid. *Colchicein*, $C_{17}H_{21}NO_5 \cdot 2H_2O$, is in white crystals, inodorous, soluble in alcohol, chloroform, and hot water, colored green by ferric chloride, and, after several days' standing, precipitated by tannin; it has a slight acid reaction, and combines with bases, the compounds being mostly insoluble in water, but soluble in alcohol and chloroform. *Colchico-resin*, $C_{51}H_{60}N_2O_{15}$, is brown, amorphous, soluble in chloroform and alcohol, insoluble in ether, and very sparingly soluble in cold water. *Betacolchico-resin*, $C_{34}H_{30}NO_{10}$, is blackish-brown, soluble in strong alcohol and chloroform and insoluble in water and ether. The last two principles are not, or but slightly, affected by tannin, are colored brown-green by ferric chloride, and dissolve in potassa with a brown color. Colchicine and colchicein yield with potassa a yellow solution. The four principles yield with sulphuric acid and potassium nitrate a deep-blue or purplish-blue color, and when this has disappeared concentrated potassa solution produces a more permanent brick-red color. By heating colchicein with hydrochloric acid at $115^{\circ} C.$ ($239^{\circ} F.$), Zeisel (1883) obtained methyl chloride and *apocolchicine*, the hot aqueous or dilute alcoholic solutions of which solidify on cooling to a gelatinous mass. Its salts are amorphous; its solutions in acids are intensely yellow, and are precipitated by the group-reagents for alkaloids. Ferric chloride gives a brown-green precipitate soluble with a green color in hydrochloric acid. The behavior to sulphuric acid and potassium nitrate is similar to that described above.

Colchicine is usually prepared by exhausting with alcohol, evaporating, diluting with water, filtering, precipitating coloring matter with subacetate of lead, removing excess of lead by sodium phosphate, and precipitating colchicine with tannin; the washed tannate is digested with lead oxide and dried, when alcohol dissolves the colchicine. Eberbach's process is a modification of that of Geiger and Hesse: he exhausts with alcohol containing $\frac{1}{4}$ per cent. sulphuric acid; to the tincture calcium hydrate is added, and to the filtrate, if necessary, sulphuric acid, to exact neutralization; the alcohol is distilled off, the residue diluted with water, filtered, the filtrate treated with ammonia, and then agitated with chloroform. Hertel's pure colchicine is made by adding magnesia to the tincture of the unbroken seeds, distilling off the alcohol, diluting the cold residue with water, separating the fat, and extracting the principle with chloroform; the yield is 0.4 per cent.

A. Aschoff (1857) obtained from 1 pound of dry tubers, collected in October, 6.5 grains of colchicine; the amount then decreased, and was in May 0.75 grain, and for the young tuber 6.5 grains. 2 pounds of fresh ($= 4\frac{1}{2}$ oz. dry) colchicum-flowers yielded 7 grains, but if collected without the underground portion of the tubers, only 2 grains. The flowers, if properly gathered, furnish, therefore, quite an active medicine. 1 pound of seeds yielded 15 to 19 grains; J. E. Carter obtained only 6.7 grains.

The remaining constituents of the tuber are medicinally unimportant; they comprise starch (about 10 per cent.), gum, sugar, tannin, and fatty resinous and coloring matters. The seeds contain much sugar, a little acid reacting like gallic acid, and a fixed oil amounting to between 6 and 8 per cent.

Pharmaceutical Preparations.—**ACETUM COLCHICI.** Digest for a week 1 part of bruised colchicum-seed in 9 parts of dilute acetic acid and 1 part of alcohol, and filter.—*P. G.* 1872. Colchicum-root 1 part, white wine vinegar 12 parts.—*F. Cod.*

OXYMEL COLCHICI. Mix vinegar of colchicum 1 part and clarified honey 2 parts, and evaporate to 2 parts.—*P. G.* 1872.

2. Seed: Extract. colchici seminis fluid., *U. S.*; Tine. colchici (colchi. sem.), *U. S.*, *Br.*; Vinum colchici seminis, *U. S.*

Physiological Action.—Colchicum and its alkaloids, whether given to certain animals by the mouth or veins or hypodermically, produce essentially the same symptoms. They consist of violent (and even bloody) vomiting and purging, great nervous exhaustion, and signs of extreme suffering. After death intense vascular congestion is found in the gastro-intestinal mucous membrane and in the kidneys: the blood is dark and thick, not only in the veins, but even in the heart and arteries—in consequence, no doubt, of the great loss of its watery element by vomiting and purging. The experiments of Rutherford and Vignal led them to conclude that “colchicum, although it increases the amount of biliary matter excreted by the liver, renders the bile more watery.” According to Rossbach, the most characteristic effect of colchicine is complete paralysis of the central and peripheral terminations of the nerves. This effect involves sensibility, motility, and reflex excitability. It is remarkable that the action of the alkaloid is very slowly developed, and that even in experiments causing death the fatal result is delayed for several hours. Upon man the operation of colchicum and its preparations does not differ essentially from that just described. Its topical action is shown by the redness, pricking, and diminished sensibility of the skin produced by the application of the fresh cornus. Applied to the tongue, it occasions an acrid, bitter, and astringent taste, irritation of the fauces with salivation, and a sense of tension and pain, followed by insensibility and rigidity of the organ, and sometimes profuse pyalism. Medicinal doses, insufficient to produce any gastro-intestinal irritation, diminish the frequency of the pulse and probably increase the proportion of solids in the urine. These statements are not sustained by uniform evidence. According to Dr. Granville Faught (*Inaug. Thesis*, Univ. of Penna., 1879), who studied the action of wine of colchicum-root in his own person, it increases the proportion of water and of free uric acid in the urine, and diminishes that of urea. In studying the action of this drug too little care has been taken to distinguish between cases into which no disturbing element entered, and those in which the emeto-cathartic operation of the drug took place, and in which, therefore, the urinary secretion was necessarily diminished. It is very certain that there is nothing in its eliminative action by the kidneys or by the bowels to explain its curative virtues.

When moderate doses of colchicum have been repeated for several days or a single large dose has been taken, some heat is felt in the epigastrium, with eructations, and perhaps nausea. Under its continued action the appetite fails, the tongue becomes coated, and there is some colic, with gurgling and diarrhœa. In doses of from 1 to 4 drachms within 24 hours it occasions bilious vomiting, with colic and straining, heat in the anus, and bloody and mucous stools. It is said that the abdomen is not tender under pressure, and cases of colchicum-poisoning indicate that the statement is true.

Poisonous doses of colchicum, apart from the symptom just alluded to, occasion all the signs of violent gastro-intestinal irritation, a true cholera morbus, with griping, vomiting, diarrhœa, prostration, and painful spasms of the limbs and trunk, followed by resolution and collapse, in which death occurs without delirium or coma. It probably is due at last to cardiac syncope. After death the most notable changes consist of lividity of the skin in depending parts, engorgement of the veins, with dark pitchy blood in the lungs, brain, and trunk, sometimes a dark-colored injection of the gastro-intestinal mucous membrane and submucous ecchymoses, and more or less shedding of the intestinal epithelium. The kidneys are pale. It is alleged that colchicum or its alkaloid is sometimes used in the manufacture of beer to simulate the bitterness of the hops, which are deficient. A case is recorded in which several persons who each had drunk about a glass of English beer were seized with vomiting and purging, heat of head, etc., and the beer, on examination, was found to contain colchicine.

It may be concluded that colchicum acts chiefly upon the digestive organs and upon the nervous system, and probably favors the elimination of effete matters through the bowels, the kidneys, and, in a slight degree, through the skin.

Medical Uses.—The chief use of colchicum is in the treatment of *gout*, for which disease it was anciently employed, and only fell into neglect through the prevalence of absurd medical theories which condemned it because their authors could not comprehend its operation. Only within the first quarter of the present century was it revived, after the discovery that the virtues of an unquestionably efficient quack-remedy for the cure of gout were due to colchicum. As a general rule, it acts much more favorably upon

acute than chronic gout, and upon first attacks than upon those which are frequently repeated; it does not agree with old persons as well as with the young or the middle-aged; and usually, although by no means uniformly, its favorable operation is attended with an increased secretion of bile and urine, free alvine discharges without diarrhœa, and a moist state of the skin. Its curative effects are not to be secured by allowing it to excite vomiting or purging, but are retarded and rendered incomplete by such evacuations. These evils should be avoided by commencing the administration with small doses of the drug. A repetition of the gouty attacks renders larger doses necessary, and in course of time they are apt to resist the medicine completely. Before commencing the use of colchicum in this disease it is profitable to remove the contents of the alimentary canal by means of a purgative. A draught containing sulphate of magnesia, with magnesia or its carbonate, in an aromatic water, is the most appropriate form of prescribing it.

Much has been written of the virtues of colchicum in *rheumatism*, and some reputable physicians have estimated them highly; but a close inquiry leaves no doubt that whatever good may have been achieved was due either to the violent purgative operation of the medicine or to the agents with which it was associated. The recent hypodermic use of colchicine for the same disease is mentioned only to be condemned. The local action of the alkaloid is very irritating. The same remark applies with equal force to the use of the medicine in *cholera*, *tetanus*, *neuralgia*, diseases of the *skin*, etc., but it is possible that it may exert a salutary diuretic action in *dropsy* depending upon congestion or infarction of the kidneys. Its importance in this affection compared with that of *digitalis* is almost null.

The *dose* of the dried cormus of colchicum may be stated at from 2 to 8 grains (Gm. 0.10–0.50), and, according to some persons, this form of the medicine is the most efficient. But the wines or the extracts are usually preferred.

COLLINSONIA.—HORSEBALM.

Richweed, *Stone-root*, *Knob-root*, *Heal-all*, E.; *Guérit-tout*, *Baume de cheval*, Fr.; *Collinsonie*, G.

Collinsonia canadensis, Linné. Meehan, *Native Flowers*, ii. 165.

Nat. Ord.—Labiatae.

Description.—A perennial herb about 3 or 4 feet (.9 or 1.2 M.) high, growing in rich woodlands in North America from South Carolina northward. It has a nearly horizontal and irregularly-branched rhizome, having, together with the branches, a length and width of 3 to 6 inches (7 to 15 Cm.), and on the upper side a very knotty and tuberculated appearance from the numerous short projecting branches and the many shallow concave stem-sears; the lower surface is much less knotty, and bears many thin nearly simple rootlets or their remnants. It is externally of a grayish- or yellowish-brown color, has a very thin bark of a slight nauseous taste, and a very hard, whitish wood. The stem is quadrangular and hairy above; the leaves are opposite, petiolate, 3 to 8 inches (7 to 20 Cm.) long, thin, nearly smooth, ovate, pointed, sometimes rather heart-shaped at the base, coarsely serrate, and somewhat dotted beneath. The flowers are in loose racemes, of a greenish-yellow color, the lower lip of the corolla fringed and with two exerted stamens. The herb has when rubbed a strong and usually disagreeable odor, but occasionally it is more pleasant and anise-like. Its taste is pungent. Like other Labiatae, it contains a volatile oil, but it has not been chemically examined.

Medical Action and Uses.—From the fact that this plant contains an acrid volatile oil which it loses in drying, and that it has been popularly regarded as a remedy for various forms of debility or oppression, it must be held to possess stimulant virtues. Their special direction appears to be toward the urinary organs, since it is esteemed most in *dropsy*, *gravel*, and *vesical catarrh*; and toward the skin, since it is employed as a diaphoretic in *rheumatism* and *fevers*. Doubtless, the latter object is best secured by a hot, and the former by a cold, infusion of the plant. The essential oil has been used separately, and probably contains all the curative virtues of the herb. The fresh-bruised herb has been employed for the relief of the eruption produced by *poison sumach*, as a vulnerary, and as an anodyne for *colic* and other *local pains*, especially in hot fomentations. Next to the essential oil, an infusion of the bruised fresh plant is to be preferred, which in dropsical affections may be prepared with cider.

COLLODIUM, U. S., Br., P. G.—COLLODION.

Collodion, Fr.; *Collodium*, *Kollodium*, G.

Preparation.—Pyroxylin 4 parts (200 grains); Stronger Ether 70 parts (3500 grains or 10½ fluidounces); Alcohol 26 parts (1300 grains or 3½ fluidounces), to make 100 parts (5000 grains or 11⅔ oz. av. or 14½ fluidounces). To the pyroxylin, contained in a tared bottle, add the alcohol, and let it stand for 15 minutes; then add the ether, and shake the mixture until the pyroxylin is dissolved. Cork the bottle well and set it aside until the liquid has become clear. Then decant it from any sediment which may have formed and transfer it to bottles, which should be securely corked. Keep the collodion in a cool place, remote from lights or fire.—*U. S.*

The British Pharmacopœia directs the dissolution of 1 ounce of pyroxylin in a mixture of 36 fluidounces of ether and 12 fluidounces of rectified spirit. The proportions of the German Pharmacopœia are 1 part of gun-cotton to 21 parts of ether and 3 parts of alcohol. The pharmacopœias order the solution to be poured off from any sediment which may form, and which by the U. S. P. 1870 was ordered to be reincorporated by agitation before using the collodion.

Properties.—If the pyroxylin—or, more correctly, *colloxylin*—has been properly made, there is no difficulty in preparing collodion by simply agitating it occasionally with the liquid. It forms a neutral, nearly clear, or slightly opalescent, either colorless or slightly yellowish, liquid having a syrupy consistence and ethereal odor. On evaporation it forms a colorless, glossy, and contractile film, which is more or less white and opaque if applied with the insoluble sediment.

Pharmaceutical Uses.—Collodion and flexible collodion may be used as an excellent vehicle for the local application of medicinal substances soluble in ether, such as aconitine, atropine, tannin, ferric chloride, carbolic acid, the oleoresins of capsicum, pepper, etc., camphor, corrosive sublimate, red iodide of mercury, etc.

Medical Uses.—These are treated of under COLLODIUM FLEXILE.

COLLODIUM CUM CANTHARIDE, U. S.—COLLODION WITH CANTHARIDES.

Collodium cantharidatum, P. G.; *Collodium cantharidale s. vesicans*.—*Cantharidal collodion*, E.; *Collodium vésicant* (s. *cantharidé*, *cantharidal*), Fr.; *Blasenziehendes Collodium*, *Kantheriden-Kollodium*, G.

Preparation.—Cantharides, in No. 60 powder, 60 parts (12 ounces); Flexible Collodion 85 parts (17 ounces); Commercial Chloroform, a sufficient quantity. Pack the cantharides firmly in a cylindrical percolator, and gradually pour commercial chloroform upon them, until 250 parts (50 ounces) of tincture are obtained, or until the cantharides are exhausted. Recover, by distillation on a water-bath, about 200 parts (40 ounces) of the chloroform, and evaporate the residue in a capsule, by means of a water-bath, until it weighs 15 parts (3 ounces). Dissolve this in the flexible collodion, and let it stand at rest for 48 hours. Finally, pour off the clear portion from any sediment which may have been deposited and transfer it to bottles, which should be securely corked. Cantharidal collodion should be kept in a cool place, remote from lights or fire.—*U. S.*

Chloroform is a better solvent for cantharidin or the cantharidin compound contained in old Spanish flies; but if such be used it would seem to be of advantage to treat the powder by Dragendorff's process (see page 376), when cantharidin will be set free, as shown by Fahnstock (1879). Powdered cantharides being much lighter than chloroform, their percolation with this menstruum presents some difficulty unless pressed down by a layer of washed sand. Owing to the volatility of the chloroform, percolation should be performed with an apparatus such as is used for the percolation of ethereal liquids (see OLEORESINÆ), and the greater part of the menstruum remaining absorbed in the powder may be recovered by judicious percolation with water. If the proper precautions be observed in distilling the chloroformic tincture, the loss of chloroform will be insignificant. The present formula is similar to that of Procter (1852), in which, however, ether was used for exhausting the cantharides; the inflammability of this liquid and its vapor requires additional precautions in distilling the tincture.

The U. S. P. 1870 directed the exhaustion of the cantharides by means of ether and alcohol, a portion of the ethereal percolate being preserved, while the remaining percolate was evaporated, the residue mixed with the reserved portion, and the preparation finished by adding the requisite amount of pyroxylin, castor oil, and Canada turpentine. For reasons

stated under CANTHARIDES their exhaustion is better accomplished by acetic ether than by ether.

The German Pharmacopœia directs this collodion to be made by macerating 50 parts of coarsely-powdered cantharides with 80 parts of ether, and filtering; in the filtrate, which should weigh 42 parts, 2 parts of pyroxylin are to be dissolved, with the addition of 6 parts of alcohol. The process evidently involves a loss of one-half of the active matter.

Properties.—Cantharidal collodion has the same physical properties as flexible collodion, except that it is of a brownish-green color, which becomes yellowish on exposure to light; it is therefore best kept in amber-colored vials. The film left on evaporation has also a greenish color.

Medical Uses.—See the following article.

COLLODIUM FLEXILE, U. S., Br.—FLEXIBLE COLLODION.

Collodium elasticum, P. G.—*Collodium élastique*, Fr.; *Elastisches Collodium*, G.

Preparation.—Collodion 92 parts ($11\frac{1}{2}$ oz. av.); Canada Turpentine 5 parts ($\frac{5}{8}$ oz. av. = 27 $\frac{3}{4}$ grains); Castor Oil 3 parts ($\frac{3}{8}$ oz. av. = 163 grains); to make 100 parts (12 $\frac{1}{2}$ oz. av. or 15 $\frac{1}{4}$ fluidounces). Mix them and keep the mixture in a well-corked bottle in a cool place, remote from lights or fire.—U. S.

This is nearly identical with the formula of the British Pharmacopœia; the German Pharmacopœia directs the dissolving of 1 part of castor oil in 49 parts of collodion.

Properties.—This preparation has the same appearance as collodion, but on evaporation it forms an elastic and scarcely contractile film.

Medical Action and Uses.—When collodion is spread upon the skin the evaporation of its ether causes its dissolved constituents to solidify and contract. As it then becomes very adhesive, the parts to which it is applied are constricted during the process, and therefore are measurably rendered anæmic, so that congestion, inflammation, and pain in them are prevented or reduced. The film formed by collodion in drying is impermeable to air and water, and therefore protects the parts underneath it, while its transparency permits them to be seen. The adhesive, protective, and contractile powers of collodion have been variously applied. In *wounds* of the scalp it serves to attach to the shaven skin slips of parchment, between whose opposite edges sutures are inserted to draw them together. In other simple incised wounds it is applied while the edges of the wound are kept accurately coaptated, the skin being first made perfectly dry. Collodion is often serviceable as a coating to *ulcers* which will not heal in consequence of the moisture of the locality or its liability to mechanical irritation. Of the former sort are ulcers of the neck of the *uterus*; of the latter, various ulcers of the *skin*. The application should be made first at some distance around the sore, and gradually advance to its centre, which ought to be left open for the escape of the secretions. Its protective and constricting properties are sometimes employed in the treatment of *carbuncles*. As in the case just mentioned, the application should be made widely around the swelling, whose central portion should be left free. The same qualities render it available in preventing and in treating *bed-sores* and *sore nipples*. Its protective action has been employed to prevent *abrasions* and other *wounds* from becoming infected during surgical and obstetrical operations and in *dissections*. Its constricting operation enables it to control *hæmorrhage* from leech-bites and other small wounds, to diminish the inflammation produced by the *stings of insects* and the local phenomena of *erysipelas*, *burns*, and *small-pox*, in the latter of which it is thought to prevent pitting. For the last three purposes it is necessary to modify the action of the collodion so as to render it less rigid when hardened. A mixture of 1 part of castor oil with 15 of collodion is said to have this effect, or the official flexible collodion may be used. With a similar object collodion has been applied with more or less success to the treatment of a variety of limited cutaneous eruptions, such as *intertrigo*, *acne*, *eczema*, and *herpes zoster*. In the last-named affection it certainly lessens the pain. In several of these disorders a preparation of collodion has been used containing vegetable and mineral astringents, as tannic acid in the official *styptic collodion*. Collodion may be employed to reduce the swelling of gonorrhœal *orchitis*, the skin of the swollen testicle being tensely drawn before the application is made. It has also been used with advantage in the treatment of *varicocele*. In *retracted nipple* a zone of this liquid, applied so as to encircle the nipple at the distance of a quarter of an inch, will sometimes cause it to protrude. Its constricting action and its mechanical support render it efficient in preventing protrusion of the bowel in umbilical *hernia*, and even in some cases of inguinal hernia; and the same is true of its use in cases of *spina bifida*, *vascular nævi*,

and *cephalæmatoma* after puncture. It may be used for a similar purpose in the treatment of *sprains*, its application being renewed as fast as the existing film becomes loose. It has been employed with alleged success to prevent nocturnal *urination* in children, by closing the orifice of the urethra by means of it at bedtime; but this is a clumsy expedient. In applying the *actual cautery* its action may be limited by including the skin about to be burned within a broad and thick circle of collodion.

Various substances of a caustic nature, such as cantharides, croton oil, iodine, corrosive sublimate, iodide of zinc, chromic acid, etc., and certain astringents, such as tannin, the salts of iron and copper, etc., have been associated with collodion for local application. Cantharidal, flexible, and styptic collodions are official.

Before applying collodion the skin should be perfectly dried, and, the liquid having been laid on with a soft brush, the first layer should be allowed to harden before a second is applied. For protective purposes a thin film will suffice; for constriction a thicker coating is required. In dressing wounds a piece of patent lint or of linen cambric saturated with the liquid should be laid upon the part after the edges of the wound are accurately coaptated. If a firm dressing without constriction is desired, flexible collodion is to be preferred.

COLLODIUM STYPTICUM, U. S.—STYPTIC COLLODION.

Collodium hæmostaticum.—*Styptic colloid*, *Xylostyptic ether*, E.; *Collodion au tannin*, Col. *styptique*, Fr.; *Tannin-Kollodium*, G.

Preparation.—Tannic Acid 20 parts (80 grains); Alcohol 5 parts (20 grains or 26 minims); Ether 20 parts (80 grains or 116 minims); Collodion 55 parts (220 grains); to make 100 parts (400 grains or about 1 fluidounce). Introduce the tannic acid into a tared bottle, add the alcohol, ether, and collodion, and agitate until the tannic acid is dissolved. Keep the product in well-corked bottles in a cool place, remote from lights or fire.—U. S.

This preparation was originally suggested by Dr. Benjamin W. Richardson (1867), who added a small quantity of tincture of benzoin. A somewhat similar but much stronger preparation is the one recommended by Pavesi, consisting of tannin 5 parts, carbolic acid 10 parts, benzoic acid 3 parts, and collodion 100 parts.

Medical Uses.—It is difficult to understand how tannic acid enclosed in an insoluble matrix can operate as an astringent. Such, however, is the purpose supposed be accomplished by this preparation, already referred to under COLLODIUM FLEXILE.

COLOCYNTHIS, U. S.—COLOCYNTH.

Poma colocynthisidis.—*Bitter apple*, E.; *Coloquinte*, Fr.; *Koloquinten*, G.

The fruit of *Citrullus* (*Cucumis*, *Linné*) *Colocynthis*, *Schrader*. Woodville, *Med. Bot.*, plate 175; Bentley and Trimen, *Med. Plants*, 114.

Nat. Ord.—Cucurbitaceæ.

Official Parts.—1. COLOCYNTHIS, U. S.; *Fructus colocynthisidis*, P. G.—Colocynth, E.; *Coloquintes*, Fr.; *Koloquinten*, G.—The fruit deprived of its rind.

2. COLOCYNTHIDIS PULPA, Br.—Colocynth-pulp, E.; *Pulpe de coloquinte*, Fr.; *Koloquintenmark*, G. The decorticated fruit freed from the seeds.

Origin.—The colocynth-plant has a perennial root, an herbaceous, angular, hispid stem, with many-lobed hairy leaves, short branching tendrils, and solitary axillary unisexual flowers with a yellow corolla.

It is said to be indigenous to Japan, and is met with abundantly from the sandy lands of Coromandel north-westward to the Caspian Sea, and westward throughout Western Asia to Greece, throughout Northern Africa, and as far south as Nubia, Senegambia, and the Cape of Good Hope. It is cultivated and naturalized in Spain.

Description.—The fruit, called *gourd* or *pepo*, resembles an orange in size and appearance, is globular, 2 to 4 inches (5 to 10 Cm.) in diameter, and covered with a smooth and thin but firm, parchment-like rind of a light brownish-yellow

FIG. 82.

Peeled Colocynth:
longitudinal and transverse section.

color. The rind is usually removed, sometimes from the fresh, but more frequently from the dried, fruit. In the former case the white or yellowish-white pulp is considerably shrunk, so as to closely envelop the seeds; in the latter case the fruit has retained its original size and shape, but shows upon the surface of the spongy pulp the smooth cuts with a sharp knife. It is destitute of odor, but has an intensely bitter taste, is very light, and divided into three easily separable cells by the parietal placenta, which project to near the centre, are then branched, turned back toward the rind, and here curved inward again, so that by the development of each placenta three slightly-united wedges are formed, each being again divided into two parts. The naturally one-celled fruit has therefore the appearance of being six-celled, and the seeds being borne on the incurved ends of the placenta in two, or sometimes three, rows, there are at least four rows of seeds in each wedge or twelve rows in the fruit. The seeds are flat ovate, with a rounded edge, brownish or yellowish, and contain an oily embryo with two thick cotyledons. The pulp consists of roundish, thin-walled, loosely-united parenchyma-cells, containing a little granular matter and becoming larger toward the centre; the thin fibro-vascular bundles form in the outer layer an irregular circle and are scattered in the interior. Good colocynth yields from 65 to 72 per cent. of seeds and from 28 to 35 per cent. of pulp, the latter alone being employed in medicine. The oily and slightly bitter seeds, freed from the adhering bitter pulp and from the integuments, are used as food in some parts of Africa. According to Flückiger, the dried pulp yields 11 per cent. of ash, and the seeds 2.7 per cent. of ash and 17 per cent. of fixed oil.

Colocynth reaches commerce from Syria, Egypt, Morocco, and Spain. The Syrian variety is often peeled while fresh, and when dry is of a very shrivelled and unsightly appearance, but is rarely met with in our commerce. 27,555 pounds of colocynth were imported into this country in 1867.

Some other cucurbitaceous fruits have a very bitter taste, and are reputed to be purgative, like *Cucumis trigonus*, *Roxburgh*, *Cuc. Hardwickii*, *Royle*, of the East Indies, and *Cuc. prophetarum*, *Linné*, of Arabia.

Constituents.—Colocynth has been analyzed by Braconnot, Vauquelin, Herberger, Meissner, Bastick, and others. The medicinally unimportant constituents are pectinaceous, mucilaginous, and gummy matter, fixed oil, and salts. Walz (1858) first published a process for obtaining the bitter principle *colocynthin* in a pure state by exhausting the alcoholic extract with cold water, precipitating the filtrate with acetate and subacetate of lead, removing excess of lead with sulphuretted hydrogen, precipitating with tannin, diffusing the precipitate in alcohol, and decomposing with plumbic hydrate. Any lead taken up by the liquid is removed by hydrogen sulphide, the clear liquid evaporated, and the residue washed with ether. The undissolved portion is *colocynthin*, $C_{36}H_{54}O_{23}$ (?), an amorphous yellow mass which appears to become crystalline on the slow evaporation of its alcoholic solution. On boiling with dilute acids it splits into sugar and resinous *colocyntherin*. The portion of the alcoholic extract remaining undissolved by cold water contains a tasteless crystalline principle, *colocynthitin*, which is soluble in ether, alcohol, and hot water. Hübschmann (1858) obtained nearly 3 per cent. of colocynthin by treating the alcoholic extract of colocynth with hot water, concentrating the liquid, precipitating it with excess of potassium carbonate, dissolving the dried precipitate in alcohol, adding 8 volumes of ether, decanting, agitating with animal charcoal, filtering, and evaporating. Henké (1883) prepared apparently a purer colocynthin by precipitating with strong tannin solution and decomposing with lead carbonate; the yield was only 0.6 per cent. of the pulp. It is a pale-yellow uncrystallizable powder, soluble in 20 parts of cold and 16 parts of hot water, readily soluble in alcohol, sparingly soluble in absolute alcohol, and insoluble in ether, chloroform, benzol, benzin, and carbon bisulphide.

Pharmaceutical Uses.—*FRUCTUS COLOCYNTHIDIS PRÆPARATI*, s. *Trochisci alhandal*, P. G., 1872. It is prepared by triturating 5 parts of colocynth-pulp and 1 part of powdered gum-arabic with sufficient water to form a paste, which is dried and reduced to a fine powder having a yellowish color.

TINCTURA COLOCYNTHIDIS, P. G. Tincture of colocynth is made by macerating for 8 days 1 part of colocynth-fruit, with the seeds, with 10 parts of alcohol sp. gr. 0.832, expressing, and filtering. It is of a yellowish color, very bitter, and becomes opalescent when mixed with water.

For medicinal purposes an *impure colocynthin* has been proposed, to be made by treating the alcoholic tincture with animal charcoal or by mixing the powdered colocynth with and packing it upon some animal charcoal, and then displacing with alcohol; on evap-

orating, a garnet-colored mass is obtained soluble in water and alcohol and insoluble in ether. It has been used in doses of $\frac{1}{4}$ to $\frac{1}{2}$ grain.

Off. Prep.—Extract. colocynthidis, *U. S.*; Extr. colocynth. comp., *Pilula colocynth. comp.*, *Pil. colocynth. et hyoseyami, Br.*

Physiological Action.—Unless in very large doses, colocynth acts feebly upon horses, sheep, and swine. It purges dogs and rabbits violently, causing exhaustion, with inflammation of the bowels. The experiments of Rutherford and Vignal led them to the following conclusions: 1. Colocynth is a hepatic stimulant of considerable power; it renders the bile more watery, but increases the secretion of biliary matter. 2. It is also a powerful stimulant of the intestinal glands. In man small doses of it appear to quicken intestinal peristalsis and augment the mucous and biliary secretions. The stools are generally mucous and watery, and are attended with colic. In excessive doses it operates as a violent emeto-cathartic, causing vomiting and serous or bloody stools, severe burning and colicky pains, and muscular spasms, such as are apt to occur in all severe gastrointestinal irritation. It has been known to cause death with these symptoms or with the addition of peritonitis. Solutions of colocynth applied to the unbroken skin of the abdomen have occasioned purging, and still more readily when the cuticle was removed.

Medical Uses.—Colocynth is used as a purgative when it is intended to produce a copious secretion and rapid evacuation from the bowels, and at the same time a derivative operation upon their mucous integument. Thus, it is employed simply as an *evacuant* when fecal or other accumulations obstruct the intestine, and in this way also it becomes a *vermifuge*. In a similar manner, partly, it is used to promote indirectly the absorption and discharge of *dropsical effusions*, these collections being absorbed in proportion as the blood-vessels lose their watery contents through the bowels. It is one of the drastic cathartics which were anciently employed to cure *melancholia*, and which for this purpose are probably undervalued at the present day. In many cases of the affection the scybulous dejections, muddy skin and eye, foul tongue, tender liver, and loaded urine are speedily modified by active purgation, and with their abatement the mental torpor is removed. In *coma*, *apoplexy*, and recent *paralysis* of congestive origin colocynth will often prove a valuable revulsive. On the other hand, its irritation of the bowel, by extending to the bladder, urethra, or uterus, sometimes serves to cure *vesical paralysis*, *chronic urethritis*, and *amenorrhœa* depending upon torpor of the uterine system. Colocynth has been used as a *diuretic* in dropsy, but the proof of its efficacy is insufficient.

Neither colocynth nor its simple extract is, at the present day, often administered alone, but usually in combination with rhubarb, aloes, scammony, and mercurials. As a laxative the *dose* may be stated at from 2 to 5 grains (Gm. 0.10–0.30), and as a drastic purgative at from 5 to 10 grains (Gm. 0.30–0.60) three or four times a day. The tincture (P. G.) is an efficient preparation.

COLUTEA.—BLADDER SENNA.

Baguenaudier, Séné indigène, Fr.; Falsche Senna, G.

The leaves of *Colutea arborescens*, *Linné*.

Nat. Ord.—Leguminosæ, Papilionacæ.

Origin.—The bladder senna is a South European shrub about 10 feet (3 M.) high, with small racemes of yellow flowers and greenish inflated legumes containing many roundish blackish-brown seeds.

Description.—The leaflets are in four or five pairs, oval or elliptic, obtuse or emarginate at the apex, regular at the base, thin, smooth, and dark-green above, pale-green beneath, and clothed with appressed hairs. They have a feeble odor and a nauseous and bitter taste. They have occasionally been used for adulterating senna-leaves.

Constituents.—Bladder senna has not been analyzed.

Medical Action and Uses.—The leaves and seeds of this plant are slightly purgative, and the latter were formerly regarded as emetic also. It has been used chiefly as a domestic purgative in some parts of Europe, in an infusion prepared with an ounce of the leaves to a pint of water (Gm. 32 to Gm. 500), with the addition of liquorice-root and anise-seed, and taken in divided doses in the morning, fasting. The powder and the extract have also been used, but the former is not tolerated, owing to its offensive taste, and the same objection lies against the infusion. The smoke of the dried leaves is said to act powerfully as an *errhine*. It is employed in the same cases as senna.

COMPTONIA.—SWEET FERN.

Ferngale, Meadowfern, E.

The leaves and tops of *Comptonia* (*Myrica*, *Blume*) *asplenifolia*, *Aiton*, s. *Myrica Comptonia*, *De Candolle*.

Nat. Ord.—*Myricaceæ*.

Origin.—Sweet fern is a branching shrub about 3 feet (.9 M.) high, growing in sandy or sterile places in Canada and the United States southward to Virginia, and flowering in April.

Description.—The leaves are scattered, linear-lanceolate, pinnatifid, with alternate, roundish, obtuse lobes, resinous-dotted, thin, and 2 to 4 inches (5 to 10 Cm.) long. They have a peculiar resinous, aromatic odor, and an aromatic and astringent taste.

Constituents.—H. K. Bowman (1869) determined the amount of tannin contained in the leaves to be 8.20 per cent. R. T. Chiles (1873) found in sweet fern a principle analogous to saponin, resin, volatile oil, gallic acid (?), fat, and other common vegetable principles.

Medical Action and Uses.—Sweet fern is stimulant and astringent; it probably owes the former property to its essential oil, which is also the cause of its grateful fragrance, and the latter to gallic acid. A decoction of it is sometimes used to relieve *colic* and check *diarrhœa* and as a fomentation in *rheumatism*.

CONDURANGO CORTEX, *P. G.*—CONDURANGO.

The bark of *Gonolobus Condurango*, *Triana*, s. *Marsdenia Condurango*, *Reichenbach*.

Nat. Ord.—*Asclepiadaceæ*.

Origin.—The drug which first attracted attention under the above name is known in Peru as *cundurango blanco*, also as *mata perro*, or “dog-killer,” and comes from an asclepiadaceous climber, for which Dr. Ruschenberger proposed the name *Pseusmagemetis equatoriensis*, and which grows in localities from 3000 to 5000 feet above the level of the sea. The shrub is from 10 to 30 feet (3 to 9 M.) high, and has a smooth ash-gray bark, which is more or less mottled with greenish or blackish lichens. The bark is prepared for market by pounding the stem with a mallet to detach it, and then drying it in the sun, generally on skins, during 8 or 10 days.

Description.—Condurango-bark forms quills and semi-cylindrical pieces, which are about 4 inches (10 Cm.) long, $\frac{1}{2}$ to $\frac{1}{4}$ inch (2 to 6 Mm.) thick, but are often much broken; the outer surface is brownish or brown-gray, and somewhat wrinkled and warty; the inner surface is grayish or pale brownish-white; the transverse fracture is granular and slightly fibrous, and shows under the thin brown cork a whitish or yellowish-white amylaceous tissue, which is radially marked by wavy bast-wedges and dotted with numerous brownish or yellow stone-cells. When dry it is without odor; its taste is bitter and somewhat aromatic and acid.

Constituents.—Dr. Antisell (1871) ascertained the bark to contain, besides 8 per cent. of moisture, 12 of mineral salts and 80 of vegetable matter, the latter consisting of 0.7 fat, 2.7 yellow resin, 0.5 starch, gum, and glucose, and 12.6 tannin, coloring matters, and extractive, the remainder being cellulose; the bitter principle was not isolated.

Other Condurangos.—Dr. Jos. G. Ayers, U. S. N. (1871), ascertained that there are at least ten different shrubby vines designated as *cundurango*, said to mean *cayle-vine*: of the majority of these he was unable to collect the flowers and fruit. The origin of the following, however, has been determined:

Echites hirsuta, *Ruiz et Pavon*, yields *cundurango de paloma*, from Zaruma. The bark has a soft, pale-yellow, or white corky layer, which is a line or more thick.

Echites acuminata, *Ruiz et Pavon*, yields *cundurango de plátano*. The bark is thin and pale-gray on the outside.

Gonolobus tetragonus, *De Candolle*, yields *cundurango de paloma*, from Malacatos. It is of a dark-gray or brown color, and on the dry stem is slightly wrinkled longitudinally.

(Most of the above facts have been taken from the valuable *Report on the Origin and Therapeutic Properties of Condurango*, by W. S. W. Ruschenberger, M. D., U. S. N., Washington, 1873.)

Medical Action and Uses.—This plant, which exhibits hardly any active properties, was in 1871–72 proclaimed to be a cure for *cancer*, and for a short time attracted professional notice. It, however, speedily lost its ephemeral reputation when it was proved

to possess no medicinal virtues in cancer or in any other disease, except those belonging to various aromatic bitters, such as allaying vomiting and improving the appetite. According to some writers, it has been useful in rheumatism and neuralgia. It may be administered in a decoction made with half an ounce of the bark in a pint of water (Gm. 32 in Gm. 500), reduced to half a pint, of which a tablespoonful is given three or four times a day. The same decoction has been used topically.

CONFECTIONES.—CONFECTIONS.

(*Conservæ* and *Electuaria*).—*Electuaries*, E.; *Conserves*, *Électuaires*, *Saccharolés mous*, Fr.; *Conserven*, *Latwergen*, G.

These preparations are now but little employed medicinally, compared with the extensive use made of them during the past century, when many medicinal substances were preserved and exhibited in the form of soft solids sweetened by sugar or honey. A distinction was then, and in some countries is still, made between *conserves* and *electuaries*, which in the British and U. S. P. Pharmacopœias are now comprised under the title of confections.

CONSERVES were made by covering fresh drugs with a layer of sugar; afterward by beating fresh vegetable substances with sufficient sugar until the whole was converted into a uniform soft mass. As indicated by the name, the primary object in view was to preserve the medicinal virtues of the plants thus treated, and incidentally their administration was rendered more agreeable. Fresh plants not being at all seasons attainable, it became customary to use some in their dried condition, either in the form of powder or unpowdered, and to beat them with the requisite quantity of water and sugar. Medicinal roots not containing enough moisture were usually steeped in hot water before the sugar was added.

ELECTUARIES differ from conserves mainly in being mixtures of powders with pulps, syrups, or honey, and are made by triturating the ingredients together in a mortar. The powders should be very fine; when extracts are to be added they are previously liquefied by trituration with a little water or other suitable menstruum, and gum-resins, if not pulverizable, are best converted into an emulsion to ensure their uniform distribution. Soluble as well as insoluble salts may be given in this form, but of the latter kind only the lighter ones should be used, since heavy insoluble salts are apt to gradually subside in the soft mixture. Of other insoluble substances, volatile oils should first be rubbed with a portion of the sugar or an absorbent powder, and fixed oils are suspended in mucilage before they are incorporated.

If intended to be kept on hand, electuaries are made of such a consistence that they are rather soft, but at the same time firm enough to prevent the separation of the ingredients. For immediate use they are made somewhat softer, so that the mixture, when taken upon a spatula, will gradually drop off; they are then in a condition to be swallowed without mastication, and if partial separation should have occurred on standing, a uniform mixture is readily obtained again by stirring.

If the main excipients of electuaries are pulps and honey, they will for a long time ensure a proper consistence and prevent the preparation from becoming hard and dry. With sugar as the principal constituent, as in the case with conserves, the gradual evaporation of water will often cause it to become hard and the sugar to crystallize; it should then be worked over, if necessary, with the addition of a little water or glycerin, but the substitution of common for refined sugar should not be resorted to.

Two confections only have been admitted in the new U. S. P., and one in the P. G. Formulas for those which have been dismissed will be found under the head of the principal drug contained therein.

CONFECTIO OPII, *Br.*—CONFECTION OF OPIUM.

Electuarium theriac.—*Électuaire opiacé*, *Thériaque*, Fr.; *Opiumlatwerge*, *Theriak*, G.

Preparation.—Mix compound powder of opium 192 grains with 1 fluidounce Imp. meas. (= 583 grains) of simple syrup.—*Br.* 40 grains of this confection represent 1 grain of opium. The same quantity is contained in 50 grains of confection made by the French Codex, which orders not less than sixty ingredients. The latter resembles

the *Mithridatum* and *Confectio Damocratis* of the past century, which preparations contained about one-fourth of the above proportion of opium. Confection of opium has very properly been dismissed from the new U. S. P. and P. G.

Medical Uses.—Introduced as a substitute for the ancient compound, theriaca, it is peculiarly useful in simple *diarrhœa* affecting persons of a debilitated and especially a gouty habit of body, and feeble digestion associated with flatulent colic, and during the exhausting heats of summer. 1 grain of opium is contained in 36 grains of the mass, and therefore, as the bulk of the medicine may be objectionable where a strong anodyne impression is desired, the proportion of the narcotic may be increased extemporaneously.

CONFECTIO PIPERIS, *Br.*—CONFECTION OF PEPPER.

Electuarium piperis.—*Électuaire (Confection) de poivre*, Fr.; *Pfefferlatwerge*, G.

Preparation.—Take of Black Pepper, in fine powder, 2 ounces; Caraway-Fruit, in fine powder, 3 ounces; Clarified Honey, 15 ounces. Rub them well together in a mortar.—*Br.*

Medical Uses.—This confection was prepared in imitation of Ward's paste, which acquired great vogue in the treatment of *hæmorrhoids* with ulceration or a discharge of mucus. A piece of the size of a nutmeg may be taken two or three times a day.

CONFECTIO ROSÆ, *U. S.*—CONFECTION OF ROSE.

Confectio rosæ gallicæ, *Br.*; *Conserva rosarum.*—*Conserve de rose rouge*, Fr.; *Rosen-conserve*, G.

Preparation.—Red Rose, in No. 60 powder, 8 parts (2 oz.); Sugar, in fine powder, 64 parts (16 oz.); Clarified Honey 12 parts (3 oz.); Rose-Water 16 parts (4 oz.); to make 100 parts (25 oz.). Rub the red rose with the rose-water heated to 65° C. (150° F.), then gradually add the sugar and honey, and beat the whole together until thoroughly mixed.—*U. S.*

The British Pharmacopœia directs 1 pound of fresh red-rose petals to be beaten in a stone mortar with 3 pounds of sugar.

The formula of the French Codex is similar to the first one, but omits the honey. With a good quality of powdered red-rose petals a very good confection is obtained.

Pharmaceutical Uses.—It is used as an excipient in *Pilula aloes barbad.*, *Pil. aloes et assafœtidæ*, *Pil. aloes et ferri*, *Pil. aloes et myrrhæ*, *Pil. aloes socotr.*, *Pil. ferri carbonatis*, *Pil. hydrargyri*, *Pil. plumbi cum opio*, *Br.*, and is occasionally serviceable for the same purpose in extemporaneous pill-masses.

CONFECTIO ROSÆ CANINÆ, *Br.*—CONFECTION OF HIPS.

Confectio cynosbati, *Conserva cynorrhodi*, F. Cod.—*Conserve de cynorrhodon*, Fr.; *Hainbullen-Conserve*, G.

Preparation.—Take of Hips, deprived of their seeds, 1 pound; Refined Sugar 2 pounds. Beat the hips to a pulp in a stone mortar, and rub the pulp through a sieve; then add the sugar and rub them well together.—*Br.*

It is used as an excipient in *Pilula quinîæ*, *Br.*

Medical Uses.—Confection of rose or of hips is used only as an excipient for substances given in pilular form, and which it is desired to have promptly diffused in the stomach.

CONFECTIO SCAMMONII, *Br.*—CONFECTION OF SCAMMONY.

Électuaire (Confection) de scammonée, Fr.; *Scammonium-Latwerge*, G.

Preparation.—Take of Scammony, in fine powder, 3 ounces; Ginger, in fine powder, 1½ ounces; Oil of Caraway 1 fluidrachm; Oil of Cloves ½ fluidrachm; Syrup 3 fluidounces; Clarified Honey 1½ ounces. Rub the powders with the syrup and the honey into a uniform mass, then add the oils and mix.—*Br.*

Medical Uses.—This confection is intended, by the stimulants and carminatives which it contains, to moderate the drastic operation of the associated scammony. The dose is from 10 to 30 grains (Gm. 0.60–2.00).

CONFECTIO SENNÆ, U. S., Br.—CONFECTION OF SENNA.

Electuarium e Senna, P. G.; *Electuarium de senna compositum*, *Electuarium lenitivum*.—*Lenitive electuary*, E.; *Électuaire de séné composé*, *Électuaire lenitif*, Fr.; *Senna-Latwerge*, G.

Preparation.—Senna, in No. 60 powder, 10 parts; Coriander, in No. 60 powder, 6 parts; Cassia Fistula, bruised, 16 parts; Tamarind 10 parts; Prune, sliced, 7 parts; Fig, bruised, 12 parts; Sugar, in fine powder, 50 parts; Water 60 parts; to make 100 parts. Place the Cassia fistula, tamarind, prune, and fig in a close vessel with 45 parts of the water, and digest for 3 hours by means of a water-bath. Separate the coarser portions with the hand, and rub the pulpy mass first through a coarse hair-sieve, and then through a fine one or through a muslin cloth. Mix the residue with the remainder of the water, and, having digested the mixture for a short time, treat it as before and add the product to the pulpy liquid first obtained. Then by means of a water-bath dissolve the sugar in the pulpy liquid, and evaporate the whole until it weighs 84 parts. Lastly, add the senna and coriander, and incorporate them thoroughly with the other ingredients while yet warm.—*U. S.*

Take of senna, in fine powder, 7 ounces; coriander-fruit, in fine powder, 3 ounces; figs 12 ounces; tamarind 9 ounces; cassia-pulp 9 ounces; prunes 6 ounces; extract of liquorice $\frac{1}{2}$ ounce; refined sugar 30 ounces; distilled water a sufficiency. Boil the figs and prunes gently with 24 ounces of distilled water in a covered vessel for 4 hours; then, having added more distilled water to make up the quantity to its original volume, mix the tamarind- and cassia-pulp, digest for 4 hours, and rub the softened pulp of the fruits through a hair-sieve, rejecting the seeds and other hard parts. To the pulped product add the sugar and extract of liquorice, and dissolve them with a gentle heat; while the mixture is still warm add to it gradually the mixed senna and coriander powders, and mix the whole thoroughly, making the weight of the resulting confection 75 ounces, either by evaporation or by addition of more distilled water.—*Br.*

Mix powdered senna 10 parts; simple syrup 40 parts; purified tamarind-pulp 50 parts, and warm by means of a steam-bath. It is greenish-brown.—*P. G.*

The last formula is the simplest, and yields a less pleasant but equally effectual preparation. That of the French Codex is of more complex composition.

Medical Uses.—This confection forms an eligible basis for various purgative compounds, and is itself a mild and efficient laxative in the dose of 120 grains (Gm. 8).

CONFECTIO SULPHURIS, Br.—CONFECTION OF SULPHUR.

Electuarium sulphuris.—*Électuaire (Opia) de soufre*, Fr.; *Schwefel-Latwerge*, G.

Preparation.—Take of Sublimed Sulphur 4 ounces; Acid Tartrate of Potash, in powder, 1 ounce; Syrup of Orange-Peel 4 fluidounces. Rub them well together.—*Br.*

Medical Uses.—Like confection of senna, this preparation is well adapted to procure copious semi-solid stools without actively purging or causing irritation of the rectum. These qualities adapt it for use as a laxative in hæmorrhoidal cases. The dose is from 1 to 2 drachms (Gm. 4–8).

CONFECTIO TEREBINTHINÆ, Br.—CONFECTION OF TURPENTINE.

Electuarium terebinthinatum.—*Électuaire (Opia) térébenthiné*, Fr.; *Terpentinöl-Latwerge*, G.

Preparation.—Take of Oil of Turpentine 1 fluidounce; Liquorice-Root, in powder, 1 ounce; Clarified Honey 2 ounces. Rub the oil of turpentine with the liquorice, add the honey, and mix to a uniform consistence.—*Br.*

Medical Uses.—In this mixture the repulsive taste of the oil of turpentine is masked by the liquorice-powder more thoroughly than can be effected in an emulsion. It is used occasionally for passive hæmorrhage, flatulence, lumbricoid worms, rheumatism, etc. The dose is 1 or 2 drachms (Gm. 4–8).

CONIUM, U. S., Br., P. G.—CONIUM.

Hemlock. Poison or spotted hemlock, E.; *Grande ciguë*, *Ciguë officinale*, Fr.; *Schierling*, *Gefleckter Schierling*, G.

Conium maculatum, *Linné*, s. *Cicuta maculata*, *Lamarck*. Bentley and Trimen. *Med. Plants*, 118.

Nat. Ord.—Umbelliferae, Campylospermæ.

Official Parts.—1. *CONII FOLIA*, *Br.*; Herba conii. *P. G.*; Herba cicutæ majoris.—Hemlock-leaves, *E.*; Feuilles de grande ciguë, *Fr.*; Schierlingskraut, Schierlingsblätter, *G.*

The leaves, also fresh leaves and young branches, *Br.*

2. *CONIUM*, *U. S.*; *Conii Fructus*, *Br.*, *U. S.* 1870.—Hemlock-fruit, *E.*; Fruits de grande ciguë, *Fr.*; Schierlingsfrüchte, *G.*

The full-grown fruit, gathered while yet green (ripe, *Br.*).

Origin.—Spotted hemlock is indigenous to the temperate countries of Asia, Europe, and Northern Africa, and has been naturalized in some portions of New England and

New York and in South America. It grows in waste places and along streams. It has a biennial, whitish, nearly simple or somewhat branched root, and a round furrowed stem, which is 6 to 8 feet (1.8 to 2.4 M.) high, hollow except at the joints, smooth, glaucous, and covered with numerous brown or brown-red spots. The numerous branches are terminated by umbels of ten to twenty rays, with the one-sided involuclers of three or four ovate or lanceolate bracts united at the base, and with small white flowers.

FIG. 83.

Conium: fruit and longitudinal section, magnified 3 diameters; transverse section, magnified 8 diameters.

Description.—1. **THE LEAVES.** The lower leaves are about 1 foot (30 Cm.) long, upon long, hollow, and sheathing petioles, broadly ovate or triangular in general outline, pinnately decomposed, with the pinnae oblong-lanceolate, pinnatifid, or incised, the upper ones toothed, each lobe or tooth terminating with a small whitish point. The upper leaves are smaller, almost sessile, and

less decomposed; all are smooth. In the fresh state they are of a dull dark-green color above, paler and somewhat glossy beneath, and acquire on drying a dull grayish-green color and a characteristic odor, which has been likened to that of the urine of mice; their taste is nauseous, saline, somewhat bitter and acrid. They are collected from plants in full bloom when the fruit begins to form; on drying they lose about 85 per cent. in weight.

The leaves of *Æthusa Cynapium*, *Linné* (Bentley and Trimen, *Med. Plants*, 125), *Anthriscus sylvestris*, *Hoffmann*, and different species of *Chærophyllum*, have been occasionally collected in place of conium; but the plants have only a superficial resemblance to the latter, and the leaves do not agree with all the characters given above. The first plant is known as Fool's parsley, Small hemlock, *E.*; Éthuse, Petite ciguë, Ache des chiens, *Fr.*; Hundspetersilie, Gartenschierling, *G.* It is indigenous to Europe and Northern Asia, and is somewhat naturalized in North America. The leaves resemble conium-leaves in outline and subdivision, but the secondary pinnae are rhomboid-ovate and pinnatifid or bipinnatifid, with narrow lanceolate acute segments; they are dark-green above, somewhat paler and glossy beneath, and when bruised have a disagreeable somewhat leek-like odor. The other plants mentioned have pubescent or ciliate leaflets.

2. **THE FRUIT.** The fruit is about $\frac{1}{8}$ inch (3 Mm.) long, broadly ovate, somewhat compressed at the sides, crowned with the short stylopodium, and readily separating into the two mericarps, each one marked on the back with five wavy crenate ribs, which become nearly smooth in the ripe fruit. The furrows are faintly wrinkled longitudinally, and, like the face, destitute of oil-tubes. The integuments of the fruit are convex upon the face and penetrate into the albumen, which upon a transverse section shows a roundish heart-shaped or reniform outline. The fruit has a green or gray-green color, or is grayish if collected as directed by the British Pharmacopœia. It is nearly inodorous and has but a slight taste: when triturated with an alkali, it evolves the disagreeable odor of the leaves. Conium-fruit has been occasionally observed as an adulteration of anise, to which, when ripe, it bears some resemblance.

Constituents.—The most important constituent of both drugs is the volatile alkaloid coniine, or *conine*, which, according to A. W. Hofmann (1881), has the formula $C_8H_{17}N$. Giseke (1827) obtained it as an impure sulphate; Geiger (1831) prepared it pure. It is contained in the distillate, prepared with an alkali from the drug or its extract, and freed from ammonia by converting it into sulphate and exhausting this with a mixture of strong alcohol and ether, which leaves ammonium sulphate undissolved; coniine may then be liberated by treatment with an alkali and distillation, but, though colorless, is accompanied by *conhydrine* or *conydrine*, and often by methyleconiine, the former of which is left in the

retort on the careful distillation of the colorless crude coniine. *Conhydrine* forms pearly iridescent laminae which are easily fusible, sublime above 150° C. (302° F.), and have a slight odor of coniine. It was discovered by Wertheim (1856). Examined by A. W. Hofmann (1882), it was found to melt at 120° C. (248° F.), to boil at 226° C. (439° F.), and to have the composition, $C_8H_{17}NO$, assigned to it by Wertheim; but on treatment with phosphoric anhydride or strong hydrochloric acid it yields an oily distillate of a coniine-like odor, containing several bodies not identical with this base. *Coniine* is a colorless, inflammable, oily liquid, specific gravity 0.88 to 0.89, has a strong alkaline reaction, a penetrating suffocating odor, and when pure the boiling-point 168° to 169° C. (334.4° to 336.2° F.). It dissolves its own weight of cold water, which is separated again on warming; it is soluble in all proportions in alcohol, ether, chloroform, benzol, benzin, and fixed oils, is less freely soluble in carbon bisulphide, and requires 100 parts of cold water for solution. Like ammonia, it forms dense white fumes with volatile acids, combines with acids to salts, precipitates most metallic salts, some of the precipitates, like silver, being soluble in an excess, and it neutralizes acids, forming salts which are freely soluble in water and alcohol, are usually deliquescent, and occasionally uncrystallizable, and are not precipitated by platinic chloride. Its hydrochlorate and hydrobromate are, according to A. W. Hofmann (1881), easily obtained by dissolving coniine in anhydrous ether and passing into the solution dry hydrochloric or hydrobromic acid gas. The salts, being insoluble in ether, are precipitated in a white crystalline form; both are very soluble in water and alcohol, are not deliquescent, and may be dried at 100° C. (212° F.) without decomposition. Coniine deviates polarized light to the right, while *paraconiine*, $C_8H_{15}N$, so called from the supposed identity of its formula with that of coniine, is optically indifferent. This alkaloid was artificially prepared by Schiff (1871).

Conium-fruit contains, besides the usual principles, also a fixed oil, a minute portion of non-poisonous volatile oil having the odor of cumin, and probably malic acid in combination with the alkaloids. The herb contains acetates and malates, and a non-poisonous volatile oil of a disagreeable odor, and yields about 12 per cent. of ash. The amount of alkaloid in the herb is minute, but appears to vary; the mature but still green fruit contains about 0.8 per cent. or less of coniine; conhydrine is always present in very minute proportion.

The herb of fool's parsley was stated by Ficinus to contain a crystallizable poisonous alkaloid, *cynapine*, said to be soluble in water and alcohol, but insoluble in ether. But Walz (1859) and Bernhardt (1880) obtained from the fruit a volatile oily base resembling coniine.

Off. Prep.—1. Of the leaves: Cataplasma conii, Extractum conii, Succus conii, *Br.* 2. Of the fruit: Abstractum conii, Extract. conii alcohol., Extract. conii fluid., *U. S.*; Tinctura conii, *U. S.*, *Br.*

Physiological Action.—*On Animals:* The effects of conium upon various animals accidentally poisoned by it or made the subjects of experiment with its different preparations agree essentially in the occurrence of paralysis, first of the voluntary muscles, and then of the muscles of respiration, and, through the latter operation, in the production of death by asphyxia. Experimenters are not agreed whether it directly slows the heart, or does so indirectly, or, finally, whether it does so at all. Nor is it certain, according to them, whether the toxic and paralyzing operation of the drug proceeds from the spinal centres to the periphery or commences in the terminal nerves, but the latter opinion seems to be the more generally accepted. It is alleged that in either case the muscular contractility is unimpaired. It would seem that if the dose be not directly lethal convulsions may occur before the death of the animal, but otherwise death takes place without spasm. It is not clear that anæsthesia precedes death in animals unless the poisoning be slow. Nor is it quite certain, according to the same authorities, what influence conium and its alkaloid exert upon the animal temperature; for while it is generally maintained that they diminish it, one writer at least asserts that they decidedly increase the temperature of animals poisoned by them. While one affirms that in poisonous doses they prevent the coagulation of the blood, rendering it dark and fluid, another declares that the blood does not appear to undergo any alteration and that the corpuscles retain their power of absorbing oxygen. One asserts that coniine is not eliminated with the urine, while others have found it in that secretion. These antagonistic results of experiments conducted under determinate conditions illustrate the difficulty of drawing definite conclusions from such data, and the wisdom of preferring clinical bases for clinical rules.

Since the second edition of this work (1879) more thorough investigations of conia and

its derivatives have tended to narrow the divergencies of opinion respecting their mode of action. In 1878, Rochefontaine and Tiryakian concluded that coniine is neither a muscular nor a cardiac poison, and that it does not seem to act on the sensitive nerves, but upon the cerebro-spinal centres, increasing reflex excitability, suspending voluntary movement, and producing, in its first degree of action, hurried respiration and disorders of vision, and in its full development loss of reflex excitability, feeble respiration and pulse, and finally collapse (*Archives gén.*, 7^{ème} sér. ii. 244). Precisely similar conclusion were arrived at by Tuloup (*Bull. de thérap.*, c. 286). Meanwhile, more thorough and logical results were obtained by Prévost (*Archives gén.*, 7^{ème} sér. iv. 374). He showed that hydrobromate of coniine is identical in its action with coniine, and that it paralyzes the nerves, and not their central origins. On cutting off all communication of a limb with the body of an animal except through the nerves, and then administering the agent, he found that the limb retained excitability, while all other parts lost it. This result was rendered more distinct when the animal was strychninized. He further found, in poisoning by coniine, that if artificial respiration is maintained the heart is the last organ to die, and that its movements continue longer than those of the normal heart would do after the suspension of artificial respiration. As a necessary induction from these results, he concluded that coniine probably does not act upon the nervous centres, and that the convulsions attending death under its influence are owing to asphyxia produced by paralysis of the respiratory muscles through the pneumogastriacs. Prévost found coniine in the urine, the saliva, and the tears. Dolan failed to find it in the milk (*Practit.*, xxvii. 164). Although the general results of Hoffmann's experiments agreed with those just summarized, he nevertheless contended for a powerful action of coniine on the medulla oblongata and spinalis (*Archiv. f. experiment. Pathol. etc.*, xv. 46), and the same conclusion was reached by Boehm (*ibid.*, p. 439). In 1880, Rochefontaine announced that conium contains two principles, one of which paralyzes the central nervous system, while the other, like woorara, paralyzes the nerves themselves. Schulz in 1881 (*Zeitsch. f. klin. Med.*, iii. 21) pointed out in detail the analogies between the two principles, thus: Both act on the extremities of the nerves, and do not affect muscular contractility; are prevented from acting on a muscle by ligating the blood-vessels supplying it; paralyze the vagus sooner than the nerves of the muscles; and both act similarly upon secreting organs. As far as the action of curare upon the brain is known, it resembles that of coniine. Hydrobromate of coniine does not irritate the animal tissues, and is therefore appropriate for hypodermic use.

On Man: There is no apparent relation between the physiological and the toxical effects of conium on the one hand and its medicinal operation on the other, and in this it resembles a very large number of medicines. Supposing a really efficient preparation to be employed, the action of small and continued doses of it is exhibited by an increase of the perspiration and the urine, but the latter does not appear to contain coniine; the appetite, digestion, and defecation are improved, and the strength and flesh are increased. But a very protracted use of the drug produces an opposite condition, with impaired nutrition, which mainly affects the glandular organs, so that the mammae and testes may undergo atrophy. The analogy of these effects with those of iodine is striking. In large but not toxic doses it renders the pulse somewhat slower and fuller and the temperature slightly lower; it sometimes occasions a papular or erythematous eruption upon the skin, injection of the eyes, a sense of fulness in the head, giddiness, some cloudiness of sight, feebleness of the limbs, and diaphoresis. Still larger doses show their direct operation most evidently upon the muscular system, inducing an impression of excessive fatigue or weariness, and a gradual loss of power, beginning with the hands and feet; the eyelids fall, the eye loses its power of accommodation, and the pupils are dilated; the hearing is dull. There is no mental disorder nor drowsiness, the mind remaining calm but active. Dr. John Harley, who studied this subject with peculiar thoroughness, states the following as the effects of a full dose of conium-juice given to palliate chronic muscular spasm: "The whole muscular system is completely relaxed. The orbicularis is incapable of resistance. The movements of the eyeball are very sluggish, and there is more or less complete ptosis. The muscles of mastication and deglutition are nearly paralyzed. Speech is slow and effected with exertion; the voice is gruff, from relaxation of the laryngeal muscles. Withal, the heart and breathing are normal, sensation and intelligence are perfect, and the mind is calm." Even in fatal cases the pulse and respiration may be natural until the approach of death, which often is preceded by convulsions. The face is apt to be pale, and the hands and feet are cold and either pale or bluish. After death from conium-poisoning no lesions are

uniformly found. There is no evidence that conium impairs sensibility when taken internally. The external use of coniine may produce local effects, as where friction with an ointment containing it has temporarily caused paralysis of the fingers that applied it.

Medical Uses.—Conium has had a wide reputation for its virtues in the treatment of *cancer*, and there is no doubt that it has removed tumors supposed to be of this nature, both when used as a dressing and when given internally. That when applied locally it mitigates the pain and improves the condition of sores regarded as open cancer is certain. It is therefore a medicine not to be lightly neglected in cases of this kind. In *scrofulous* glandular sores similar good effects are sometimes observed. Enlargement and induration of the *liver* by simple engorgement or by a degree of hyperplasia, with the attendant symptoms, jaundice and ascites, appear to have been cured by a prolonged use of the medicine. During a like use of it the *mammary gland* has been known to become atrophied and its secretion to have been gradually suspended. Conium plasters were formerly used to *dry up the milk*. Dolan has praised it for chronic inflammation of the womb, and as an “excellent sedative for backache and for the sexual organs.” *Cutaneous affections*, especially those of a strumous nature, appear to be favorably modified by this medicine. The reputed benefits of conium in *melancholy* seem to be attributable rather to the associated treatment, except where the mental disorder depended upon one of the visceral infarctions above alluded to. In *mania* its sedative operation has been used to control violence, and in *erotic insanity* it appears to lessen the evidences of sexual excitement. For the latter purpose it was anciently employed. A plaster containing equal proportions of conium and belladonna extracts is an efficient palliative of intercostal *neuralgia* and of *palpitation of the heart*. In various other *neuralgic* affections conium is reputed to be efficacious, but it is probably in those only in which the paroxysm is due to congestion or other pressure upon nervous trunks. The same may be said of its use in *ophthalmia* with *photophobia*, in *toothache*, *whooping cough*, *asthma*, *spasmodic laryngitis*, *laryngismus stridulus*, and *epilepsy* due to congested conditions of the motor centres. Its efficiency in some aggravated cases of *chorea* is still more striking. In this and other spasmodic affections the full development of its physiological operation is essential to the cure. It would seem to be indicated in *puerperal* and *infantile convulsions* and in *tetanus*. In the last-named disease it is said to have effected a cure in four out of six cases (Chew, *Med. Record*, xix. 38). Dr. Harley has called attention to the utility of conium-juice in *trismus*, in *spasm of the orbicularis* and of the *gullet*, in *dislocations of joints* where the action of powerful muscles resists the efforts made to reduce them, and in cases of the *impaction of artificial teeth* in the œsophagus. He dwells upon the important circumstance that patients under its influence are not prevented from assisting the surgeon by their efforts and guiding him by their sensations.

Conium and its preparations are contraindicated in cases of great exhaustion and debility. Diseases interfering with the rhythm of the heart suggest a cautious use of the medicine.

The proper antidotes to conium-poisoning are evacuation of the stomach and the use of alcoholic stimulants, with external warmth.

Administration.—Supposing the preparation to be good—which it seldom is—the extract of conium may be given in doses of 1 grain (Gm. 0.06), repeated at intervals of an hour or more until the physiological operation begins to appear; the dose of the tincture (an ineligible preparation) is $\frac{1}{2}$ fluidrachm (Gm. 2), and of the juice the commencing dose is 1 fluidrachm (Gm. 4). The commencing dose of coniine is stated by different physicians at $\frac{1}{60}$ grain (Gm. 0.001), or even less, and the hypodermic dose of bromohydrate of coniine at $\frac{1}{5}$ grain (Gm. 0.01). According to Tuloup, Audhouin, and others, no smaller amount than 2 grains (Gm. 0.10) of the salt in the 24 hours will have much effect, and this quantity should be used in two doses, and pretty rapidly increased until 5 or 6 grains a day are given. For hypodermic use may be employed a solution of 1 Gm. of bromohydrate of coniine in 19 Gm. of distilled water. Each Gm. will contain 5 Cgm. of the salt, of which $\frac{1}{5}$ may be used for a first injection, but subsequently the quantity may be rapidly increased to 1 Gm., or even 2 or 3 Gm. “The initial dose for hypodermic injections does not differ much from what is necessary by the stomach.” By the latter way it is said that if the doses are gradually increased, 5 or even 6 grains of the salt may be given in the course of 24 hours without injury (Tuloup, *Annuaire de therap.*, 1880, p. 15).

ÆTHUSA CYNAPIUM, *fool's parsley*, has generally been alleged to be poisonous, like conium or aconite (Taylor's *Med. Jurisp.*, 1865, p. 351), and Harley collected a number of cases and statements which were supposed to prove its poisonous action; but an extended

series of experiments led him to conclude that the plant is not in any degree poisonous (*St. Thomas's Hosp. Rep.*, N. S. iv. 63; x. 257). In 1882 this conclusion was fully confirmed by Tanret, who believes the erroneous statements referred to arose from confounding *Æthusa cynapium* with *Conium maculatum*, which it closely resembles in appearance (*Bull. de thérap.*, ciii. 22).

CONTRAYERVA.—CONTRAYERVA.

Contrayerve, Br.; *Bezoarwurzel*, *Giftwurzel*, G.

The root of *Dorstenia Contrayerva*, *Linné*, and *D. brasiliensis*, *Lamarek*.

Nat. Ord.—Urticaceæ, Artocarpeæ.

Origin.—The first species is indigenous to the West Indies, Central America, and southward to Peru; the second, to Brazil and other parts of South America. Both are acaulescent perennials, with a fleshy quadrangular or circular inflorescence, in which the minute nutlets are imbedded.

Description.—The root has one or two short annulate heads, is fusiform, about $\frac{1}{2}$ inch thick, 2 or 3 inches long, and below divided into fine fibres; that of the second species is globular-ovate, about $\frac{3}{4}$ inch long, annulate, and beset with fine fibres. The color is reddish-brown, internally whitish. The bark is thick, with the inner portion of a punctate appearance, and encloses a brownish-yellow wood which is radiately marked by the medullary rays. The root has a rather unpleasant odor and a bitter and acrid taste.

Dorstenia dracena, *Linné*, *D. opifera*, *Martius*, *D. tubicina*, *Ruiz et Pavon*, and perhaps other species yield similar roots.

Constituents.—Geiger obtained from the root some volatile oil, resin, starch, and a bitter amorphous principle.

Medical Action and Uses.—Contrayerva (meaning "antidotal plant") appears to be a stimulant bitter tonic; in its native country it is used in *low fevers*, very much as serpentaria is elsewhere, and also as a remedy, both internal and local, for the *bites of serpents*. The dose of the powdered root is stated to be $\frac{1}{2}$ drachm (Gm. 2).

CONVALLARIA.—LILY OF THE VALLEY.

Lilium convallium.—*Muguet*, Fr.; *Maiblumen*, G.

Convallaria majalis, *Linné*.

Nat. Ord.—Liliaceæ, Asparagineæ.

Description.—This stemless perennial is indigenous to Europe, Northern Asia, and to the Alleghany Mountains of the United States from Virginia southward. It is frequently cultivated in gardens, and has spontaneously appeared in several places. It has a creeping, whitish, much-branching rhizome of the thickness of a quill, two, or occasionally three, elliptic and smooth radical leaves, and a one-sided raceme of about ten nodding white flowers, which are about $\frac{1}{4}$ inch long, bell-shaped, six-lobed, with the lobes recurved, have six stamens inserted near the base of the perianth, and produce globular, few-seeded red berries. The cultivated flowers are somewhat larger. They are very fragrant and have a bitter and acrid taste. The rhizome and flowers have been used in medicine; the latter, which are still official in several pharmacopœias, lose on drying about 85 per cent. of their weight.

Constituents.—The odorous principle of the flowers was obtained by Herberger (1835) in the form of volatile crystals possessing a strong odor, occasioning headache, but very fragrant when largely diluted. The bitter principle of the plant is the glucoside *convallamarin*, $C_{23}H_{44}O_{12}$, which was isolated by Walz (1858) as a white somewhat crystalline powder, has a bitter-sweet taste, is soluble in water, alcohol, and methylic alcohol, and insoluble in ether, chloroform, and amylie alcohol (Sée); but the last two solvents, according to Dragendorff (1871), take it up from the acidulated solution. It dissolves in sulphuric acid with a brown color, and, after previous moistening with water, with a violet color, the solution becoming colorless by more water. Its aqueous solution is precipitated by tannin, but not by lead salts, and when boiled with dilute acids it yields sugar and *convallamaretin*. Sée (1882) obtained the best results with the plant collected in August; on precipitating the alcoholic tincture with basic lead acetate, evaporating, diluting with water, neutralizing with sodium carbonate, precipitating with tannin, dissolving the precipitate in 60 per cent. alcohol, and decomposing with zinc oxide, 0.6 per cent. of convallamarin was obtained. He also isolated the acrid principle *convallarin*, $C_{34}H_{62}O_{11}$, in the form of rectangular prisms, which are soluble in alcohol, insoluble in ether, and sparingly

soluble in water, but foaming with it like saponin. On being boiled with dilute acids it is split into sugar and *convallaretin*.

Pharmaceutical Preparation.—**EXTRACTUM CONVALLARIÆ.** The most efficacious extract is prepared with water from the flowers and scapes, mixed with one-third of their weight of roots and leaves, collected in August (Sée).

Allied Plants.—**POLYGONATUM MULTIFLORUM**, *Allioni* (*Convallaria multiflora*, *Linne*), and **POL. OFFICINALE**, *Allioni* (*Conv. Polygonatum*, *Linne*).—Solomon's seal, *E.*; Sceau de Salomon, *Genouillet, Fr.*; Weisswurz, *Salomon's Siegel, G.*—The plants are indigenous to Europe and Northern Asia, and have simple stems with alternate sessile leaves, the axils of which contain one to five cylindrical flowers. The rhizome is horizontal, brownish-yellow, about 6 inches long, nearly cylindrical, jointed, and bears on the upper side of each joint a circular concave stem-scar; internally it is whitish, rather spongy, and has a zone of many scattered wood-bundles near the centre. Walz found in the rhizome and herb convallarin, asparagin, mucilage, sugar, starch, pectin, etc.

POLYGONATUM GIGANTEUM, *Dietrich* (*Conv. canaliculata*, *Willdenow*), and **POL. BIFLORUM**, *Elliott* (*Conv. biflora*, *Walter*), which are North American species, have rhizomes agreeing with the description just given, and are collected here as Solomon's seal.

SMILACINA RACEMOSA, *Desfontaines*, likewise indigenous to North America, has a similar rhizome, but with shorter and thicker joints, and is known as *false Solomon's seal*.

History.—The ancients used *Conv. polygonatum* as a local stimulant in the treatment of bruises and wounds and for the removal of freckles; and Galen states that owing to its nauseous and astringent taste it is not much employed internally, but adds that it is employed to stimulate uterine contractions. In Russia it is still used locally and internally for toothache (*Krebel, Volksmed., etc. Russlands*). The young sprouts of the same species were eaten in Germany like asparagus. In the commentaries of Mattioli on Dioscorides, which were published in the seventeenth century, we find this statement (*liv. iii., chap. exx.*): "According to the Germans, lily of the valley strengthens the heart and brain, and is of use in paralysis, epilepsy, spasms, vertigo, fainting, and palpitation of the heart. They prescribe it also for the stings of insects and the bites of animals, and affirm that it is of singular efficacy in inflammation of the eyes and in difficult parturition. It is used in vinous infusion," etc. The flowers of *C. majalis*, whose powerful odor when fresh occasions headache and dulness of the senses, were popularly used in the same country, when dried and powdered, as a sternutatory, and the berries in various nervous disorders, including epilepsy. The root and flowers were also employed as purgatives, and their action was compared to that of aloes and scammony. With the dried flowers fomentations were made to remove ecchymoses, and they, as well as the root, were believed to cure worms, epilepsy, and intermittent fever. Cazin took 24 grains of the fresh flowers, producing five copious stools with colic, and gave about thrice that dose to a peasant with intermittent fever, causing eight stools with more or less colic. In 1878 convallaria was pronounced "obsolete" by Bernatzik. In 1882 it was stated by Sée that "from time immemorial the Russian peasants were acquainted with it as a certain cure for dropsy," yet in *Krebel's* work on the domestic remedies of Russia convallaria does not occur in the long list of anti-hydropsics.

Physiological Action.—The experiments of Troitsky, Boioiavlensky, Walz, Sée, and others (*Edinb. Med. Jour.*, xvii. 644, 840, 928; *Bull. de therap.*, ciii. 51) agree in their results. In frogs convallaria slows the action and increases the energy of the heart, but causes an irregular tonic contraction of the ventricle, which becomes firmer until death. In warm-blooded animals the effects are essentially the same. The dog's heart becomes slower, and then irregularly asystolic, while the inspiratory acts grow fuller and slower. Ultimately, the action of the heart grows exceedingly rapid and feeble, and the inspirations, although deeper than before, finally cease after the heart's arrest. The excito-motor function of the nerves and the reflex activity of the nervous centres remain unimpaired. No diuresis is produced in healthy subjects. Convallaria, therefore, "is a poison which, like digitalis, upas-antiar, erythrophleum, etc., arrests the heart in systole, and is unlike muscarin, which stops it in diastole" (Sée). According to Dr. I. Ott, convallaria increases the arterial tension and the rate of the heart's movements, but the heart begins to fail before the tension, owing to a direct action of the poison on its muscle. It also causes clonic spasms (*Amer. Jour. of Med. Sci.*, April, 1883, p. 565). It would seem that these results are scarcely in harmony with the others mentioned. The active properties of the plant appear to depend upon the glucosides above mentioned, convallarin and convallamarin, the former of which is stated to act upon animals as a drastic purge in the dose of 5 grains (*Gm. 0.30*), while the latter is emetic even in smaller doses, and when injected into the veins reduces the pulse-rate. Hypodermically, the thirtieth.

and even the sixtieth, of a grain (Grm. 0.002 or 0.001) is fatal to pigeons, arresting the heart in systole and producing convulsions. The slowing of the heart is not attended with diminished power in that organ, but the respiratory movements were quickened (?).

Medical Uses.—The dried flowers of convallaria have been used in powder as a *sternutatory* and *errhine*, and in fomentations for the removal of *bruises*, *ecchymoses*, and *freckles*, and they, as well as the root, for the cure of *worms*, *intermittent fever*, and *epilepsy*. In Russia several species of convallaria are used as local anodynes, and in that country it was first employed for the removal of *dropsy*. The much more thorough and systematic observations of the physicians mentioned above have demonstrated that convallaria as a remedy for dropsy is indicated in the same cases for which digitalis is commonly employed—cases in which the dropsical effusion depends upon a positive or a relative inability of the heart to carry on the circulation of the blood through its own cavities, and which are clinically denoted by its palpitation and arrhythmical movements, and by signs of obstruction in other organs, such as dyspnoea, hepatic distension, gastric disorder, a diminished secretion of urine, with an excess of solids, œdema of the feet, etc. The diuretic action of this medicine, affirmed by some and denied by others, can hardly be considered as established. Still admits only its occasional, and as it were accidental, occurrence (*Times and Gazette*, Jan. 1883, p. 14); Leyden and Pel both deny it (*Centralbl. f. Therap.*, i. 68, 189), Moutard-Martin could not discern it (*Bull. et Mém. Soc. théér.*, 1882, p. 148); and Beverley Robinson did not find convallaria a renal stimulant (*Boston Med. and Surg. Jour.*, Apr. 1883, p. 374).

It is remarked by Sée that convallaria is not liable to the objections that exist against digitalis, of having an acrid taste, impairing the appetite, and occasioning nausea or vomiting. Nor does it appear to have caused any of those alarming, and even fatal, results which are chargeable to foxglove. On the contrary, it seems to improve the appetite and digestion and render the stools soluble. The *irregularity of the heart*, which it seems especially fitted to correct, arises from mechanical impediments to the circulation, and especially from mitral lesions, more than from tissue-degradation. In these cases it calms the hurry of the heart and renders its movements rhythmical, and sometimes, although less uniformly, reduces the pulse-rate, unless its acceleration has arisen as compensatory for an insufficient supply of blood. In that case the pulse falls to, or even below, its normal standard. In aortic stenosis or insufficiency convallaria, like digitalis, is of less advantage than in mitral disease. The conclusions of Dr. Pel of Amsterdam may here be quoted—viz.: “As a heart tonic (and diuretic) the medicine seems to be inoperative in failure of the left ventricle as it occurs in chronic renal disease; on the other hand, it displays in special cases of organic heart lesion, as mitral insufficiency with imperfect compensatory changes, a power of stimulating the heart, and also of causing diuresis. Nevertheless, digitalis has a more distinct and durable action, and convallaria is not able to rival it.” Germain Sée places convallaria and digitalis on nearly the same level, but assigns a superiority to the former, in that it does not suspend the action of the heart like the latter (*Bull. de théér.*, cv. 489). Gottheil (*Med. Record*, xxiv. 226) used this medicine with, to him, inconclusive results, but it does not appear whether in his cases valvular disease existed or not. It is alleged that even when palpitation is due to other than organic causes irregularity of the heart and its consequences are removed by the medicine; and although the evidence upon this point is incomplete, the statement appears to be sustained. (See case, *Med. Record*, xxiii. 133.) It is also claimed that convallaria has been proved clinically to relieve dyspnoea by deepening the inspiratory act; but in cases of valvular or muscular disease of the heart the action of the medicine upon the heart alone is sufficient to explain the relief felt in breathing. A similar remark may be made concerning its diuretic action. It is altogether secondary, and is manifested only when the dropsy, wherever situated, is of cardiac origin. But in such cases, and especially when the kidneys and the heart-muscle are sound, its influence in removing dropsy by diuresis is at least as salutary as that of digitalis, and does not involve the dangers incident to the use of that drug. As might be expected from its mode of action, the diuresis to which it gives rise does not cease abruptly on the suspension of the medicine, but is maintained for several (from 5 to 9) days longer. It causes no change in the constitution of the urine: a slight cloudiness in it, produced by heat and nitric acid, is due not to albumen, but to the resin of the plant; and, indeed, it affects no other function directly than that of the heart.

Administration.—In the cases which first drew attention to the special virtues of convallaria the Russian physicians employed an infusion of the flowers varying in strength from 10 grains to 2 drachms in 6 ounces of water, which was given in table-

spoonful doses twice a day, and also an infusion of the whole plant, made with 1 or 2 drachms in from 4 to 6 ounces of water, of which "3 or 4 spoonfuls" a day were prescribed. Sée found an infusion of the flowers inert. According to him, watery extracts are preferable, the least active being that of the leaves, then the extract of the flowers, and finally the extract made from the flowers, stems, and root. He prescribed for a daily portion from 15 to 20, or even 30, grains of the watery extract of the flowers or of the whole plant, or twice these quantities of extract of the leaves. According to Langlebert and Tanret, the best results are produced by the watery extract of the flowers and stems, along with one-third of their weight of the roots and leaves. Of this preparation the average dose is stated to be 8 grains (Gm. 0.50). It is conveniently given in simple syrup flavored with tincture of orange-peel (*Bull. de thérap.*, ciii. 74, 179). A fluid extract prepared in this country is said to be efficient in doses of from 5 to 12 drops every 4 hours (*Med. Record*, xxii. 281), or, as others say, in doses of not less than 15 or 20 drops. It has been proposed to substitute convallamarin for the preceding preparations, but clinical illustrations of its efficiency are still wanting.

Concavallaria polygonatum is represented to be emetic and cathartic, and mildly astringent and stimulant when applied topically. It was formerly used as a vulnerary, and more recently to relieve the irritation of the skin produced by poison-sumach, etc.

COPAIBA, U. S., Br.—COPAIVA.

Balsamum copaivæ, P. G.—*Balsam copaiva*, *Balsam capivi*, E.; *Copahu*, *Oleo-résine* (*Baume*) *de copahu*, Fr.; *Copaivabalsam*, G.

The oleoresin of *Copaifera Langsdorffii*, *Desfontaines*, and of other species of *Copaifera*. Bentley and Trimen, *Med. Plants*, 93.

Nat. Ord.—Leguminosæ, Cæsalpinææ.

Origin.—With the exception of two African species, the genus *Copaifera* is indigenous to the tropical part of South America, and there consists of ten species, the majority of which are medium-sized or large trees, with mostly abruptly pinnate coriaceous leaves and racemose whitish apetalous flowers, producing coriaceous obliquely elliptical or obovate one-seeded legumes. The following may be enumerated as having been mentioned as sources of copaiva: *Cop. officinalis*, *Linne* (*C. Jacquinii*, *Desfontaines*), indigenous to Venezuela, New Granada, and some West Indian islands; *Cop. guianensis*, *Desfontaines*, found in Guiana and in Northern Brazil near the Rio Negro. *Cop. Langsdorffii*, *Desfontaines*, *Cop. coriacea*, *Martius*, and others occur in various parts of Brazil. *Cop. multi-juga*, *Hayne*, is a doubtful species; *Cop. bijuga*, *Hayne*, is probably identical with *Cop. guianensis*. Copaiva has been medicinally employed in Europe since the beginning of the seventeenth century.

Collection.—In the interior of the stem ducts, sometimes of large dimensions, are formed, in which the oleoresin collects in such quantities that old stems not unfrequently burst from the internal pressure exerted by the liquid. This is gained from bore-holes or incisions made into the trunk near its base, from which the oleoresin exudes at once so abundantly that 12 pounds are sometimes obtained in the space of 3 hours. If, however, no copaiva should flow, the wound is closed with wax or clay and reopened in a fortnight, when an abundant discharge takes place. Old trees occasionally yield it two or three times a year.

Copaiva is imported in barrels principally from Para, to which place it is brought from the northern tributaries of the Amazon. It is, perhaps, in part obtained from *C. guianensis*. Notable quantities are brought from Maranhão, and some from Rio de Janeiro, the latter supposed to be procured from *C. Langsdorffii* and *coriacea*. The copaiva exported from Maracaibo and Cartagena appears to be chiefly procured from *C. officinalis*. 228,159 pounds of copaiva were imported into the United States during the year 1876-77; in the following year only 67,000 pounds; the average for seven years is 138,734 pounds.

Description.—Copaiva is a more or less clear and viscid liquid, varying in color from very light-yellow to brownish-yellow, having a peculiar aromatic odor and a bitterish, persistently acrid, and nauseous taste. Its specific gravity ranges between 0.94 and 0.99; Flückiger gives the limits between .935 and .998; by keeping it becomes thicker and denser. It is mostly transparent, at least in a thin stratum, but occasionally is slightly turbid and faintly fluorescent. Unlike wood-oil, it is not gelatinized on being heated to 130° C. It is insoluble in water, dissolves in three or four times its weight of strong alcohol, and freely in absolute alcohol, bisulphide of carbon, ether, volatile and fixed oils, acetone, and petroleum benzin; the latter solution becomes opalescent on the

addition of more (3 to 5 volumes) petroleum benzin, and deposits on standing a little resinous matter, at the same time becoming transparent again. Benzol yields with some varieties a turbid solution. The optical behavior of copaiva varies, as has been shown by Buignet (1861) and Flückiger (1867).

The different kinds are commercially distinguished by their ports of exportation, but even as obtained from the same places are not always identical in every particular. *Para copaiva* is the most limpid and the lightest kind, and frequently contains from 65 to 85 per cent. of volatile oil. *Maranhão copaiva* is a little denser, has about the consistence of olive oil, differs somewhat in odor from the preceding, and contains from 40 to 50 per cent. of volatile oil. *Rio Janeiro copaiva* resembles the last. These Brazilian copaivas yield, with one-third to one-half their weight of ammonia, compounds which form perfectly clear solutions in the volatile oils contained in them; a larger quantity of ammonia renders the solution quite milky, but in the presence of a fixed oil clear solutions are not obtained. *Maracibo copaiva* is the thickest variety, usually of a dark-yellow color and not quite transparent. It contains less volatile oil, and does not always yield a clear mixture with a little ammonia-water; but it solidifies readily with magnesia, and is well adapted for making the official *Massa copaibæ*. According to the German *Pharmacopœia*, thick copaivas are to be preferred.

Adulterations.—The variable conditions of commercial copaiva, depending on its origin from different species, renders a detection of adulterations by no means an easy task. A copaiva which dissolves clear in strong alcohol, yields with one-third ammonia a transparent mixture, is on heating free from turpentine odor, and on evaporation of the volatile oil from a flat dish (better than distillation, as directed by the U. S. P.) and subsequent cooling leaves a transparent, hard, and brittle resin, may be considered pure. Fixed oils are left behind with the resin, and render it soft and sticky; if other than castor oil is present, neither the copaiva nor the residuary resin will yield a clear solution with alcohol. Castor oil, being nearly insoluble in petroleum benzin, may be detected by shaking the suspected copaiva with 4 to 5, or even 10, volumes of that solvent, when the adulterant will separate, but the volatile oil present exerts a marked solvent power on the castor oil. Flückiger and Hanbury recommend heating the sample of copaiva with 4 parts of 85 per cent. alcohol and allowing the mixture to cool; the upper layer is then evaporated to expel the alcohol and volatile oil, and the remaining castor oil recognized by heating it with caustic soda and lime, when *cænanthol* will be formed, recognizable by its peculiar smell; even 1 per cent. of castor oil is stated to be thus detected.

When a drop of pure copaiva is evaporated from a piece of filtering-paper, it will leave a sharply-defined transparent spot of resin behind, which, if a fixed oil is present, will be surrounded by a greasy areola. Tomlinson (1864) has recommended the examination of the cohesion-figures produced by a drop upon water, which are said to be quite characteristic for pure copaiva.

The presence of other volatile oils and turpentines usually becomes quite evident by a different odor on slowly heating a little of the copaiva. Turpentine, oil of turpentine, resin, rosin oil, etc. are said to be detected by a test admitted into the P. G.: 1 part of copaiva, on being strongly shaken with 5 parts of water of 50° C. (122° F.), should yield a turbid mixture, and this, on being warmed in a water-bath, should separate again into two clear layers. Copaiva mixed with 10 per cent. of gurgun balsam yields by this treatment a permanent emulsion (Flückiger). The U. S. P. gives the boiling-point of the volatile oil (200° C. = 392° F.) as a test.

The presence of gurgun balsam in copaiva is stated to be detected by shaking together in a test-tube 19 drops of carbon bisulphide and 1 drop of the oleoresin, and adding, with some agitation, 1 drop of a cold mixture of equal parts of concentrated sulphuric and nitric acids; copaiva assumes a faint reddish-brown color and deposits resin on the side of the tube; in the presence of gurgun balsam an intense purplish-red color is produced, changing to violet, the reaction being due to the volatile oil of the adulterant. The oleoresin of *Hardwickia pinnata*, *Roxburgh*, will under the same circumstances produce a pale greenish-yellow color (*Pharmacographia*).

Constituents.—Copaiva owes its limpidity to the presence of volatile oil (see *OLEUM COPAIBÆ*), but the acrid and bitter taste is partly due to the brittle resin, partly also to a bitter principle, as shown by Flückiger (*Pharmakognosie*). On boiling copaiva with water, concentrating the aqueous liquid, and filtering from the floccules which are separated, a transparent very bitter solution is obtained, which reddens litmus and yields a copious precipitate with tannin solution. The resin possesses acid properties, and is occasionally

deposited from copaiva in a crystalline form, also from a clear mixture of copaiva and ammonia-water when exposed to a low temperature. The crystals are freed from adhering oleoresin by washing with ether, and afterward recrystallized from absolute alcohol, when, according to Schweitzer (1830), *copaivic acid* is obtained free from ammonia. Rush (1879) agitated 1 part of copaiva with 3 parts of solution of soda sp. gr. 1.30; the mixture separates into three layers, consisting of volatile oil, an aqueous alkaline liquid, and the compound of resin; the two upper layers are decanted, the resin compound well washed, dissolved in petroleum benzin, agitated with dilute hydrochloric acid, washed with water, and the benzin solution evaporated. Copaivic acid has the composition $C_{20}H_{32}O_2$, and crystallizes in small soft prisms, which are soluble in alcohol, ether, carbon bisulphide, and in fixed and volatile oils; its salts are uncrystallizable. A deposit from Para copaiva was recognized by Fehling (1841) as distinct from the above; it is *oxy-copaivic acid*, $C_{20}H_{30}O_3$. Strauss's (1865) *metacopaivic acid*, $C_{22}H_{34}O_4$, is contained in Maracaibo copaiva, from which it is obtained by agitation with ammonium carbonate and by precipitating the aqueous liquid with hydrochloric acid. When copaiva is kept on hand it gradually becomes thicker, through the alteration of the volatile oil and its conversion into a soft resinous body.

Pharmaceutical Uses and Preparations.—Copaiva is readily emulsified by the aid of yolk of egg or gum-arabic. It is sometimes given in the form of electuary, and requires then some absorbent for the volatile oil, for which purpose powdered marsh-mallow, liquorice-root, or gum-arabic is adapted; or the copaiva may be preferably fused together with some wax, spermaceti, or cacao-butter, the quantity of which will vary with the amount of volatile oil, between $\frac{1}{2}$ and 1 part. (See also *OLEUM COPAIBÆ* and *MASSA COPAIBÆ*.)

Allied Products.—*HARDWICKIA PINNATA*, Roxburgh (nat. ord. Leguminosæ, Cæsalpinieæ), is a large East Indian tree, yielding from incisions a thick, dark-brown oleoresin, which in thin layers is greenish or wine-red, transparent, but not fluorescent, and resembles copaiva in both odor and taste. Broughton (1872) obtained from it between 25 and 40 per cent. of volatile oil having the composition $C_{10}H_{16}$, the remainder consisting of several resins, but copaivic acid was not obtained.

DIPTEROCARPUS ALATUS, Roxburgh, *D. turbinatus*, Gaertner (s. D. lævis, Hamilton), *D. incanus*, Roxburgh (s. D. costatus, Gaertner), and several other species of the same genus (nat. ord. Dipterocarpaceæ) which are indigenous to various parts of India, the East Indian and the Philippine islands, yield *gurjun balsam* or *wood-oil*, obtained by cutting large holes into the lower part of the stem and charring the wood, after which the oleoresin flows abundantly. It is a viscid liquid, varying in color from greenish-gray to brownish, opaque in reflected light, but transparent and of a dark brownish or reddish tint when viewed in transmitted light; its odor is similar to but weaker than that of copaiva, and its taste is more bitter and somewhat aromatic, but not acrid. It is freely soluble in chloroform, carbon bisulphide, and volatile oils, but only partly soluble in alcohol, fusel oil, ether, and petroleum benzin. When strongly agitated with water, gradually added until 5 parts have been used, gurjun balsam furnishes a very thick emulsion, which does not become clear on warming, but on the addition of the same bulk of water the balsam separates, and the clear watery liquid has a bitter taste and an acid reaction (Flückiger). When heated in a stoppered vial to near $130^{\circ}C.$ ($266^{\circ}F.$) it has the curious property of becoming gelatinous, the fluidity not being restored on cooling. The amount of volatile oil present in gurjun balsam varies considerably: Werner (1862) obtained 15 per cent., Flückiger 45.5 per cent., and from one specimen even 72 per cent.; it is strongly levogyre, and has the composition $C_{15}H_{24}$, the density .9044 to .918 at $15^{\circ}C.$, and the boiling-point $255^{\circ}C.$ ($491^{\circ}F.$). The resin left after the distillation of the volatile oils yields to caustic potassa *gurjunic acid*, $C_{32}H_{44}O_4$, which may be obtained pure by adding to the potassa solution an excess of ammonium chloride, filtering, and decomposing with hydrochloric acid. Gurjunic acid dissolves readily in ether and strong alcohol, slowly in benzol, and with difficulty in carbon bisulphide; it melts at $220^{\circ}C.$ ($418^{\circ}F.$), and congeals again at $180^{\circ}C.$ ($356^{\circ}F.$). A crystalline neutral resin of gurjun balsam, which had been sold as copaivic acid, was found by Flückiger (1878) to have the composition $C_{25}H_{40}O_2$, to melt at $126^{\circ}C.$ ($258.8^{\circ}F.$), and to dissolve in sulphuric acid with an orange color.

LAGAM BALSAM, MINJAK-LAGAM, comes from an unknown tree in Sumatra, and closely resembles gurjun balsam. Examined by Haussner (1883), it was dingy-green in reflected and yellowish transparent in transmitted light, had a bitterish and lastingly acrid taste, and was completely soluble in alcohol, ether, benzol, chloroform, and carbon disulphide; it yields about 33 per cent. of levogyre volatile oil of the composition $C_{30}H_{42}$ and boiling at about $250^{\circ}C.$ ($482^{\circ}F.$). The acid resin is uncrystallizable, and has the composition $C_7H_{11}O_3$; the neutral resin, fused with potassa, yields phenols and formic, acetic, butyric, and aromatic acids.

Physiological Action.—In continued or excessive doses copaiva deranges the digestion, impairs the appetite, and causes eructations, nausea, and diarrhœa. It appears to augment the watery element of the urine, rendering this secretion dark, bitter, and somewhat fragrant, as well as more or less turbid from the resin of copaiva, which also

forms an iridescent pellicle upon its surface. The addition of nitric acid to the urine gives a turbid precipitate which, unlike albumen, is soluble in alcohol. Large doses or the long-continued use of copaiba also irritate the bladder, causing micturition and sometimes hæmaturia with feverishness. It appears to be excreted by the pulmonary and the cutaneous surfaces; the former is shown by the odor it gives to the breath, and the latter by the eruptions of roseola, urticaria, etc. which it occasionally excites. A very peculiar eruption has been attributed to copaiba and cubeb taken together (*Amer. Jour. of Med. Sci.*, Jan. 1881, p. 289). Copaiba impregnates the milk of nursing women, so that their infants refuse the breast. In rare instances it seems to have caused convulsions, muscular rigidity, and even paralysis. The cutaneous and nervous symptoms of copaiba are apparently owing to its essential oil, and its modifications of the mucous membranes to the resin and the acid it contains. To the resin especially its diuretic operation is ascribed. Originally suggested by Monro in 1827, the diuretic power of copaiba was again observed (Richter; Dixon), and its reality was confirmed by experiment before 1832 (Wibmer). It was afterward mentioned by systematic writers, as Pereira, Strumpf, and Garrod. From 1869 clinical illustrations of its efficacy began to abound, and were furnished by Duffin, Thompson, Lincing, and others. In 1873, Wilks showed that the resin was even more efficient in this respect than copaiba itself. In 1875, Dixon proved by three cases of dropsy that copaiba acted as a diuretic, increasing the daily quantity of urine from 8½ to 82 ounces, from 15 to 108 ounces, and from 8 to 93 ounces, in several cases. In 1876, Carter published two cases of ascites, independent of cardiac or renal disease, entirely cured by the diuretic operation of the resin of copaiba after the complete failure of other diuretics, purgatives, etc. He tested its action upon a stout man who was suffering from erythema of one leg, but otherwise healthy. It was given three times a day in doses of about 7 grains. In the first 24 hours after the medicine was begun the quantity of urine increased from 22 to 38 ounces, and finally reached 82 ounces; the specific gravity declined from 1019 to 1014; and the total solids increased from 16.25 to 40.48 Gm., of which last amount 18.48 Gm. were organic and 22 inorganic. The total solids had therefore increased fourfold. The urea, however, had increased by only four-fifths, or 18 Gm. These results have been fully confirmed by Frederick Taylor, who administered the resin in more than sixty cases of different forms of dropsy. The diuretic operation failed, however, in cases of renal dropsy depending upon tubular nephritis, acute or chronic—a fact which renders it almost certain that the diuresis produced by copaiba is due to its action upon the secreting elements of the kidneys.

Medical Uses.—The most important uses of copaiba are in the treatment of mucous profluvia, especially of the urinary and the air-passages. There can be no doubt that it acts by modifying the urine in the first, and the bronchial mucous membrane itself in the second, of these cases, and that in both it cures by a substitutive operation. It is well known that copaiba given internally does not often cure vaginal gonorrhœa, while it arrests the urethral form of the disease in the female as readily as in the male. It is also known that in hypospadiac males affected with gonorrhœa the internal administration of copaiba will arrest the discharge from behind the urethral aperture, but not from that part over which the urine does not flow. Hence an explanation of the clinical rule, to administer as much copaiba as can be taken without disordering the stomach or irritating the urinary organs. In this manner it exerts a stimulant and moderately substitutive action upon the inflamed membrane and causes a diminution of the discharge. According to some, the agent in this operation is exclusively copaivic acid, but, since the resin abundantly appears in the urine, this constituent cannot be denied its share in the cure. It is probable that the essential oil is the most active agent when copaiba cures bronchitis, since it is largely eliminated through the bronchia. During the acute stage of gonorrhœa, and also of bronchitis, copaiba is contraindicated, for in the former disease it tends to cause strangury, swelling of the testicle, and other local disturbances, while in bronchitis it is apt to arrest the bronchial secretion and thereby occasion fever and dyspnœa. Besides administering copaiba by the mouth for the cure of gonorrhœa and gleet, it has sometimes been thrown into the rectum—a clumsy, uncertain, and injurious method. It has also been injected as an emulsion into the urethra, but without decided advantage, since the urine remaining unmodified continued to irritate the inflamed mucous membrane. The urine passed by the patient taking copaiba has been used as a urethral injection for the cure of gonorrhœa—an unnecessary and barbarous expedient when so many more appropriate injections are available. *Vesical catarrh* is often greatly benefited, and may sometimes be cured by means of this medicine perseveringly administered in moderate doses. Sometimes an emulsion of it injected into the bladder has been serviceable. It is an

efficient remedy in many cases of *irritability of the bladder* depending upon previous gonorrhœa or excessive sexual indulgence. In some cases of *leucorrhœa* it is reputed to have been curative, but there is more evidence of its favorable action in the treatment of inflamed and ulcerated *hæmorrhoids* and chronic *dysentery*. In 1863 it was announced as a specific for *membranous croup*, and even in 1875 the same deceptive statement was repeated. In various inflammations of the *eye* it is reputed to have an almost "specific" influence, especially in *iritis*, *scleritis*, and *purulent ophthalmia*. In the two first-named diseases it was given internally in drachm doses, but in the last only applied upon the skin around the orbit. The evidence upon these points is inconclusive. There is more clinical proof of its curative power in *cutaneous scaly diseases*, and its correctness is rendered more probable by the well-known action of the medicine upon the skin. It has even been alleged to be an efficient remedy in *leprosy* (Simmons). Although the ordinary use of copaiva does not denote its action upon the nervous system, yet the occasional effects attributed to it seem to point in that direction. In corroboration of this view it may be mentioned that it has produced cures of *sciatica* even after the failure of numerous other medicines (March, *Times and Gaz.*, Feb. 1881, p. 237). The diuretic operation of copaiva appears to be very decided in certain cases of *dropsy*. This operation has been described in a previous paragraph. A careful examination of the clinical records touching the matter shows that the medicine is of little use in any form of dropsy depending upon renal disease, and least of all in the cases which most require it—viz. those of a scanty secretion of urine due to tubular nephritis. In cardiac dropsy the influence of the medicine is more favorable, but only in proportion as the effusion is due to general causes rather than to mechanical obstruction in the heart. The cases in which copaiva and its resin have produced the most remarkable results are those of hepatic dropsy. In the most successful of them the nature of the hepatic obstruction was only conjectural, but was probably a condition analogous to that of commencing cirrhosis. Certain it is, that in many cases of ascites which improved but slightly, or did not improve at all, under the use of the medicine, and which ultimately proved fatal, advanced cirrhosis of the liver was found after death. The dose of copaiva used in hepatic dropsy is about 20 grains three times a day.

Externally, copaiva, like other terebinthinates, serves to stimulate, and at the same time protect, parts to which it is applied. It forms an excellent dressing for *chilblains*, *sore nipples*, *anal* and other *fissures*, etc.

Administration.—Copaiva is most commonly administered in gelatin capsules, each containing about 10 drops (Gm. 0.60), which is the minimum dose. The maximum dose ordinarily given is about 1 fluidrachm (Gm. 4). Much larger quantities, even as much as an ounce, have been prescribed, but without necessity or advantage. The medicine is sometimes mixed with magnesia, with which it forms a solid and very insoluble mass. Equal quantities of copaiva and liquor potassæ make a perfect solution, which can be diluted and flavored. Next to the capsules, emulsions of copaiva are to be preferred. They are made with the yolk of egg or mucilage and some aromatic water, to which a small proportion of laudanum is usually added. Each tablespoonful should contain from 10 to 40 drops (Gm. 0.60–3.0) of copaiva.

Copal varnish has been recommended to arrest the development of *felons* by applying it previous to the suppurative stage (Isham, *Med. News*, xl. 97). No doubt it acts as other terebinthinates (copaiva, benzoin, oil of turpentine) do in the treatment of frost-bite and various local inflammations, by protecting, and the same time stimulating, the affected part.

GURJUN OIL OR BALSAM, which resembles copaiva closely in its constitution, has, like it, been used for the cure of *gonorrhœa*. In 1873 it was used in one of the British Oriental possessions, the Andaman Islands, in the treatment of *leprosy*. Twenty-four cases were submitted to this method, with the effect of healing the ulcers, while the anæsthesia greatly improved and the tubercles softened and disappeared. It was most efficient when employed externally in the form of an emulsion made with 3 parts of lime-water to 1 of the oil, with which the affected parts were diligently rubbed twice a day, and each time for the space of 2 hours. At the same time the oil was administered internally, in doses varying from 6 to 60 drops (Gm. 0.40–4.0) and finally in tablespoonful doses of an emulsion made of equal parts of the oil and lime-water.

Reports of a later date confirm the statements just made. One comes from India, and summarizes the results of using gurjun oil in leprosy thus: "It rapidly heals chronic leprosy ulcers, softens the skin, prevents the collection of flies, and is cheap" (Peters, *Practitioner*, xxiv. 122). The other is by Dr. Milroy, who treated the disease in British

Guiana. "Gurjun oil," he says, "is laxative, diuretic, and alterative, and produces perspiration in the anæsthetic parts, followed by a return of sensation. It softens the tubercles. Internally, it purges and acts on the kidneys and urine like copaiva. Of thirty-two patients under its use, great improvement occurred in sixteen, and nine more were benefited" (*Times and Gazette*, June, 1879, p. 643).

COPTIS.—GOLD-THREAD.

Coptide, Fr.; *Gelbe* (*Kleinst*) *Niesswurz*, G.

Coptis trifolia, *Salisbury*, s. *Helleborus trifolius*, *Limé*. Bigelow, *Med. Bot.*, i. t. 5; Bentley and Trimen, *Med. Plants*, 3.

Nat. Ord.—Ranunculaceæ, Aconiteæ.

Origin.—The plant is indigenous to the northern half of this continent, from Pennsylvania northward to Greenland and Labrador, and also from the northern portion of Europe and Siberia to Kamtchatka.

Description.—Gold-thread has a filiform creeping rhizome of a golden-yellow color, with very thin fibrous rootlets. The radical leaves originate from a scaly base, are petiolate and trifoliate; the leaflets are about half an inch (12 Mm.) long, ovate with a wedge-shaped base, obtusely three-lobed, and mucronately crenate; the scape is 2 or 3 inches (50–75 Mm.) long, exceeding the petioles, and bears a single yellowish-white flower producing about seven oblong follicles, which are acuminate with the persistent style and contain a few oblong, black, and glossy seeds. The whole plant is glabrous, without odor, and has a strongly bitter taste.

Constituents.—Mayer (1862) found in gold-thread berberine and a white alkaloid. Analyzed by E. Z. Gross (1873), the absence of tannin and gallic acid was established; besides some sugar, albumen, fat, and resin, two alkaloids were isolated, *berberine* and *coptine*; the latter is colorless, insoluble in alkalies, neutralizes acids, dissolves in strong nitric and hydrochloric acids without change, and produces with warm concentrated sulphuric acid a purplish color, similar to that of hydrastine. The acids naturally combined with the alkaloids have not been ascertained. The herb yielded between 4 and 5 per cent of ash, about one-tenth of which was silica.

Allied Drugs.—COPTIS TEETA, *Wallich*. The rhizome has the thickness of a quill, contains 8½ per cent of berberine, and is used in India as a pure bitter tonic.

C. ANEMONIFOLIA, *Niebold*. The rhizome of this Japanese plant is about ¼ inch (3 Mm.) thick, bristly, with short wiry rootlets, externally brown, internally bright-yellow, and has a bitter taste; it probably contains berberine.

Medical Action and Uses.—Coptis has no ascertained virtues beyond those of other simple bitters, for which, if necessary, it may be substituted. An infusion of it may be made with an ounce of the root to a pint of water (Gm. 32 to Gm. 500) and given in the dose of 1 or 2 ounces. It is used as a wash for *aphthous sore mouth*. A tincture is made with alcohol, a pint to an ounce of the bruised root. *Dose*, a fluidrachm (Gm. 4).

CORALLORRHIZA.—CORAL-ROOT.

The rhizome of *Corallorrhiza odontorrhiza*, *Nuttall*.

Nat. Ord.—Orchidaceæ.

Origin.—The plant is a parasite, of a purplish-brown color, has a slender stem about 10 inches (25 Cm.) high, and bears from eight to twenty flowers, with their lips nearly entire. It is indigenous to North America east of the Mississippi. It is not unlikely that the more common *Corallorrhiza multiflora*, *Nuttall*, may furnish some of the commercial coral-root; it is stouter, and has from fifteen to thirty flowers, which are spurred at the base and have the lip deeply three-lobed. It is found westward to the Rocky Mountains.

Description.—Coral-root consists of numerous small fleshy tubers, which are united by their broader sides and form many branches of different length, but of the same articulated appearance, resembling coral in arrangement. It is of a brown color externally, whitish within, and has, particularly in the fresh state, a peculiar odor and a bitterish and astringent taste. Its proximate constituents have not been ascertained.

Medical Uses.—There appears to be nothing to be added to the stereotyped account of this plant, to the effect that it is an active diaphoretic and useful in fevers and inflammations. It is administered in powder in the dose of 30 grains (Gm. 2) every 2 hours.

CORIANDRUM, U. S.—CORIANDER.

Coriandri fructus, Br.—*Coriander-fruit*, E.; *Coriandre*, Fr.; *Koriander*, G.

The fruit of *Coriandrum sativum*, Linné.

Nat. Ord.—Umbelliferæ, Coelospermæ.

Origin.—The plant is probably indigenous to China and to the eastern portion of the northern shore of the Mediterranean, but is now extensively naturalized in the fields of temperate Asia and Europe, where it is also cultivated. It is occasionally cultivated in the United States and in some parts of South America. It is a smooth annual about 2 feet (60 Cm.) high and of a very offensive odor, somewhat like that of bed-bugs. The leaves are decomposed, the segments of the lower ones broadly cuneate, and of the upper ones narrow and linear; the umbels are three- to five-rayed, without involucre; the umbellets six- to fifteen-rayed, with an involucre of three linear bracts. The flowers are white or rose-colored. 49,133 pounds of coriander were imported in 1866-67; in the recent returns coriander is included with caraway.

Description.—The cremocarp of coriander is nearly globular, about $\frac{1}{4}$ inch (4 Mm.) in diameter, smooth, crowned with the unequal calyx-teeth and stylopodium, and of a buff or pale brownish-yellow color. Each of the two mericarps forms a thin hemispherical shell, the two being united at the edge by the thin pericarp, thus enclosing a flattish lenticular cavity and separating only by slight pressure. The five primary ribs of each half-fruit are obsolete, forming merely raised wavy lines; the four secondary ribs are more prominent as straight ridges, and similar ridges are formed at the junction of the mericarps. The longitudinal and transverse sections of each mericarp show the albumen to be of a semi-lunar shape; upon the latter two oil-tubes are seen on the face and none on the back. On ripening the fruit becomes gratefully aromatic.

Constituents.—Trommsdorff obtained from coriander nearly one-half of 1 per cent. of volatile oil (see OLEUM CORIANDRI) and 13 per cent. of fatty matter, besides a small amount of mucilage, malic acid, and traces of tannin.

Off. Prep.—Coriander-fruit is used in preparing *Confectio sennæ*, U. S., Br.; *Mistura gentianæ comp.*, *Syrupus rhei*, *Tinct. rhei*, *Tinct. sennæ*, Br.

Medical Action and Uses.—Coriander is aromatic and stimulant, and is chiefly employed to promote the *digestion* of certain kinds of pastry, and in medicine to correct or assist the action of purgatives, such as rhubarb, senna, and jalap.

CORIARIA.—CURRIER'S SUMACH.

Redoul, *Sumac des corroyeurs*, Fr.; *Gerberstrauch*, G.

Coriaria myrtifolia, Linné.

Nat. Ord.—Coriariaceæ.

Origin.—It is a shrub about 6 feet (1.8 M.) high, growing in Southern Europe and Northern Africa.

Description.—The branches are quadrangular; the leaves opposite, 1 to 1½ inches (25 to 38 Mm.) long, on short petioles, ovate-lanceolate, acute, entire, even at the base, smooth, bluish-green, and shining above, pale-green beneath, with a strong midrib and two lateral nerves running to near the apex. The flowers are in small terminal racemes, have a bell-shaped calyx, five fleshy, scale-like petals, five long linear stigmas, and produce each five blackish-brown obliquely ovate nutlets, which are surrounded by the enlarged scales and have a berry-like appearance. The leaves have a strongly astringent, bitter, and somewhat acrid taste.

Constituents.—The leaves contain tannin, which produces blue-black precipitates with salts of iron. The poisonous principle *coriamyrtin* has been isolated and studied by Riban (1864-66), who precipitates the decoction with subacetate of lead, removes the lead from the filtrate, and evaporates to a syrupy consistence; from this residue the principle is dissolved by ether. It is in white or colorless very bitter prisms, which dissolve in 70 parts of water, in 50 of alcohol, and in less ether, chloroform, and benzol. Its composition is $C_{30}H_{36}O_{10}$. It

Coriandrum: fruit and longitudinal section, magnified 3 diameters; transverse section; magnified 8 diameters.

FIG. 85.

Coriaria-leaf.

is rendered brown by alkalies, and on being boiled with dilute hydrochloric acid yields a body which reduces Fehling's solution, but differs from sugar.

Physiological Action.—Accidental poisoning has occurred by mistaking the leaves of this plant for senna and the fruit for blackberries. Snails that lived on its leaves have poisoned those who ate them. The toxic phenomena generally consisted of nausea, vomiting, colic, trismus, and general convulsions, ending fatally in some cases within 24 hours. Experiments upon various animals gave the same general results, but rabbits were usually unaffected. But the latter animals were destroyed by coriamyrtin in the dose of $1\frac{1}{2}$ grains (Gm. 0.10) given internally, and $\frac{1}{4}$ grain (Gm. 0.008) administered hypodermically. 3 grains (Gm. 0.20) of this substance sufficed to bring on fatal convulsions in dogs in periods varying from 20 to 75 minutes. The phenomena of poisoning by the plant and its extract resemble those induced by picrotoxin, including spasm, frothing at the mouth, and contraction of the pupils; and the lesions after death present a similar analogy, for they consist of a normal appearance of the gastro-intestinal mucous membrane, congestion of the meninges, rapid occurrence of rigor mortis, distension of the heart with dark blood, and ecchymoses in the lungs. The root poison of New Zealand has been proved to be furnished by one or more species of *Coriaria*.

CORNUS, U. S.—CORNUS.

Dogwood-bark, E.; Écorce de cornouiller à grandes fleurs, Fr.; Grossblüthige Kornelrinde, Hornbaumrinde, G.

The bark of the root of *Cornus florida*, *Limé.* Bigelow, *Med. Flora*, t. 28; Bentley and Trimen, *Med. Plants*, 136.

Nat. Ord.—Cornaceæ.

Origin.—The tree is found in woodlands from Canada southward throughout the United States east of the Mississippi; it is usually from 15 to 20 feet (4.5 to 6 M.) high, and in favorable localities attains double that height. The opposite leaves are ovate, pointed, about 4 inches (10 Cm.) long, and become crimson in autumn; the small greenish flowers are in capitate clusters surrounded by four large involueral leaves, which are notched at the apex, of a white color, sometimes tinged with purple, and quite showy. The drupaceous fruit is bright red.

Description.—The bark of the root, which is preferred, is usually met with in commerce, and is in broken somewhat curved pieces, about $\frac{1}{8}$ inch (3 Mm.) thick and rarely over 2 inches (5 Cm.) long and wide. The furrowed corky layer is dark ash-colored or brown-gray, in the young bark smooth and marked with small oblong white spots. The Pharmacopœia directs the corky layer to be removed, when the outer surface is of a pale reddish- or light reddish-brown color, and rather darker than the inner surface, which is of a rusty rose-color and striate; the longitudinal as well as the transverse fracture is short, of a whitish color, and with brown-yellow striae of stone-cells. It is almost without odor and has an astringent and bitter taste.

Constituents.—Geiger (1836) separated the bitter principle, *cornin* or *cornic acid*, by treating the cold infusion with plumbic hydrate, evaporating the filtrate, treating the extract with absolute alcohol, adding ether, and crystallizing. Frey (1879) found it difficult to obtain the principle pure without loss. It is in white, silky bitter needles, readily soluble in water and alcohol, slightly soluble in ether, colored dark by alkalies, and precipitated by silver nitrate and basic lead acetate, but not by other normal salts. We observed (1859) that the bitter principle when in aqueous solution containing a little ammonia is altered and destroyed by exposure to air and heat. Geiger separated also a tasteless resinous body crystallizing in shining needles. Cockburn (1835), besides some unimportant principles, recognized the presence of gallic acid and tannin, producing a bluish-black color with iron. Bowman (1869) obtained only 3 per cent. of tannin. Frey, in addition to these principles, isolated a bland inodorous orange-colored fixed oil, and ascertained that the resin dissolves with an orange color in cold sulphuric acid.

Off. Prep.—Extr. *cornus floridæ fluid.*, U. S.

Allied Plants.—1. *CORNUS CIRCINATA, L'Heritier.*—Round-leaved dogwood, *E.*; *Cornouiller à feuilles arrondies, Fr.*; *Canadischer (Rundblättriger) Kornel, G.*—This shrub is met with in Canada, and in the United States as far south as Virginia and west to Indiana, growing in copses in rich soil. It attains a height of 6 to 8 feet (1.8 to 2.4 M.), has greenish warty dotted branches and orbicular or broadly ovate opposite leaves, which are 5 inches (12 Cm.) or less long, abruptly pointed and white woolly beneath. The white flowers are in flat cymes; the fruit is drupaceous, light blue. The bark is in thin, irregular pieces or short quills,

which are externally greenish and warty when from young branches, or from older branches of a brownish-gray color, with the warts confluent in slightly-raised longitudinal lines of a glossy brown. The inner surface is cinnamon-brown, even, and very finely striate. The bark breaks with an even scarcely fibrous fracture through the pale-reddish inner layer. The odor is slight; the taste not unpleasant, somewhat astringent, and bitter. Rob. Gibson (1880) found it to agree in composition with the official bark.

2. *CORNUS SERICEA*, *Linné*.—Swamp dogwood, Silky cornel, Red hosier, Kinnikinnick, *E.*; Cornouiller soyeux, *Fr.*; Sumpfkornel, *G.*—This common shrub is found in moist woods, on the margins of streams and swamps, from Canada south to the mountains of South Carolina. It is 6 to 10 feet (1.8 to 3 M.) high, has purplish branches and opposite, elliptic-ovate, and pointed leaves, which are covered underneath with rust-colored silky down. The yellowish-white flowers are in close, flat, and woolly pubescent cymes, followed by pale-blue fruits. The bark is usually in much broken pieces, resembling the preceding, but having a distinct purple tint and being less warty. Its constituents are probably the same.

3. *CORNUS MASCUULA*, *Linné*.—Cornelian cherry, *E.*; Cornouille, *Fr.*; Kornelkirsche, Dürhlitz, Herlitze, *G.*—A shrub or small tree indigenous to Southern and Central Europe, and somewhat cultivated in the United States for ornament. It is 10 to 20 feet (3 to 6 M.) high, and produces, preceding the leaves, capitate umbels of yellow flowers surrounded by a four-leaved dingy-yellow or greenish involucre. The bright-red glossy elliptic drupe is about $\frac{1}{4}$ inch (2 Cm.) long, in the green state strongly astringent, but when ripe of an acidulous sweet and slightly astringent taste, and edible.

Medical Action and Uses.—Dogwood is tonic, astringent, and slightly stimulant, and in the recent state is apt to produce nausea. Like other vegetable bitters, it has been popularly used as a remedy for *intermittent fever*. Its virtues as a stomachic *tonic* are more demonstrable. The dose of the powdered bark as a tonic is about 20 grains (Gm. 1.30), and three times that quantity, repeated six or seven times during the apyrexia, may be given in intermittent fever. A decoction or the official fluid extract is to be preferred.

Swamp dogwood (*C. sericea*) is less, and round-leaved dogwood (*C. circinata*) more, bitter than this species, while the first-named excels in astringency.

CORYDALIS.—TURKEY CORN.

Squirrel corn, Turkey pea, E.

The tubers of *Dicentra canadensis*, *De Candolle*, s. *Delytra eximia*, *Pursh*.

Nat. Ord.—Fumariaceæ.

Origin.—The plant is a perennial, has bi-ternate somewhat glaucous radical leaves, with the leaflets dissected into linear-oblong segments and several scapes bearing about four greenish-white flowers, which are tinged with purple, nearly $\frac{1}{2}$ inch (12 Mm.) long, heart-shaped, and have two short and rounded spurs. It grows in rich rocky woods as far south as Kentucky, but is more frequent farther north and in Canada.

Description.—The thin subterranean shoots bear small tubers, which are collected. They are depressed globose, $\frac{1}{4}$ to $\frac{3}{8}$ inch (6 to 10 Mm.) thick, of a tawny-yellow color, nearly smooth, with a scar on each of the depressed sides, internally yellow or yellowish-white. The tuber breaks with a somewhat horny or slightly mealy fracture, is nearly inodorous, and has a bitterish and rather persistent taste.

Constituents.—W. T. Wenzell (1855) obtained from it corydaline, fumaric acid, yellow bitter extractive, an acid resin, starch, and other common principles of plants. The alkaloid was obtained by evaporating the tincture, separating the resin by filtration, precipitating the filtrate with ammonia, and exhausting the precipitate with alcohol. This solution was evaporated, the residue treated with dilute hydrochloric acid, the salt thus formed again precipitated by ammonia, and the alkaloid purified by repeated crystallization. *Corydaline* was discovered by Wackenroder (1826) in the tubers of *Corydalis tuberosa* and *fabacea*. It is a white amorphous powder, crystallizing from alcohol in colorless prisms and scales, its solution having a very bitter taste. It is soluble in alcohol, ether, chloroform, and in the fixed and volatile oils, fuses at about 70° C. (158° F.), yields mostly amorphous salts, and is colored dark-red by sulphuric acid and yellow by nitric acid, or, if it contains resin, blood-red by the last-named agent.

Allied Plants.—*CORYDALIS TUBEROSA*, *De Candolle*.—Fumeterre bulbeuse, *Fr.*; Hohlwurz, Helmwurz, *G.*—It is indigenous to the hilly woodlands of Europe. The tubers vary from $\frac{1}{2}$ to 3 inches (1 to 4 Cm.) in thickness, are roundish, gray-brown, internally greenish-yellow or whitish, firm; when old, hollow and frequently lobed.

COR. FABACEA, *Persoon*, another European plant, has small tubers which are never hollow.

DICENTRA EXIMIA, *De Candolle*, s. *Corydalis formosa*, *Pursh*, indigenous to the United States,

has a scaly rhizome and a compound raceme of oblong purplish flowers, which are about $\frac{3}{4}$ inch (18 Mm.) long and have two very short saccate spurs.

Medical Uses.—As long ago as 1855 it was stated that “the root of *C. formosa* is supposed to be tonic, diuretic, and alterative, and is given in syphilitic, scrofulous, and cutaneous affections in the dose of from 10 to 30 grains.” Since then there appears to have been nothing more definite made known respecting the virtues of this plant. The resin which it contains, and on which depend whatever virtues it may possess, is probably worthy of being suitably tested. Numerous species of *Corydalis* occur in Europe, from one of which a resin is obtained, by precipitation from a tincture, which is alleged to have cured *intermittent fever*; and another, *C. tuberosa*, is regarded as *emmenagogue*, *anthelmintic*, etc.

CORYLUS.—HAZEL.

Noisetier, Fr.; *Hasel*, G.

Nat. Ord.—Cupuliferae.

Description.—The following species have been used:

CORYLUS AVELLANA, *Linné*, is a shrub 10 to 15 feet (3 to 4.5 M.) high, common in woodlands and thickets in Europe and Northern Asia, and cultivated to some extent in the United States. It has somewhat hairy, roundish-ovate, and pointed leaves, with a heart-shaped base, flowers in March, and ripens its fruit in autumn. It has bony nuts, which are enclosed in a bell-shaped involucre, are nearly an inch (25 Mm.) long, and have a smooth, light-brown, woody shell enclosing a white, oily, and sweetish kernel. The nut is known as *jilbert*. The seeds contain over 50 per cent. of fixed oil. *Hazelnut oil* is pale-yellow, inodorous, has a mild nutty taste, and congeals at about -17.8° C. (0° F.); it consists of olein, arachin, palmitin, and stearin. By nitric acid it becomes greenish, and by sulphuric acid bluish-green and gray.

CORYLUS AMERICANA, *Walter*, is common in thickets in North America, has obovate-cordate and acuminate leaves, and yields a fruit about $\frac{1}{2}$ inch (13 Mm.) long and wide, which is enclosed in an open involucre of about twice the length of the fruit.

CORYLUS ROSTRATA, *Aiton*, grows in Canada, in the northern part of the United States, and along the Alleghanies, and is about 2 to 5 feet (0.6 to 1.5 M.) high. The leaves are oblong-ovate, pointed, and somewhat heart-shaped. The fruit is enclosed in a long hirsute involucre, which above is contracted into a long tubular beak.

Medical Uses.—The spiculæ which cover the involucre of the last-named species have been used with alleged effect as a substitute for those of *Mucuna* in the treatment of *intestinal worms*.

COTULA.—MAY-WEED.

Herba chamomillæ foetidæ.—*Wild chamomile*, *Dog chamomile*, E.; *Herbe de chamomille puante*, *Herbe de maroute*, Fr.; *Hundskamillen-Kraut*, G.

The herb of *Maruta Cotula*, *De Candolle*, s. *Maruta foetida*, *Cassini*, s. *Anthemis Cotula*, *Linné*.

Nat. Ord.—Compositæ, Anthemideæ.

Description.—This nearly smooth annual is originally indigenous to Europe, but is now a very common weed in many parts of North America, growing along roadsides, in neglected fields, and in waste places. The stem is about a foot (30 Cm.) high, with ascending branches from the base, cylindrical, furrowed, somewhat hairy above. The sessile leaves are obovate in outline, thrice pinnately divided, with linear subulate lobes, pale-green, and slightly hairy beneath. The flower-heads terminate the branches upon soft hairy peduncles. The numerous involucreal scales are somewhat imbricate, ovate, with whitish scarios margins. The receptacle is conical, not hollow; chaff nearly subulate, shorter than the florets; ray-florets white, ligulate, three-toothed, neutral; disk-florets tubular, yellow; akenes obovoid, ribbed, and without pappus. The plant begins to flower in June, and has an unpleasant aromatic odor and a bitterish acid taste.

Constituents.—The flowers were analyzed by Wm. H. Warner (1858), and found to contain a little volatile oil, some tannin, valerianic and oxalic acids, an acid fatty substance, bitter extractive, etc. Pattone (1859) announced the discovery of an alkaloid, *anthemidine*, and of a crystallizable bitter acid, *anthemidic acid*, the latter of which is dissolved from the aqueous extract by alcohol and is also soluble in ether. The undis-

solved portion of the extract, taken up with water and treated with ammonia, is said to yield the alkaloid, which, however, has not been obtained since.

Medical Action and Uses.—May-weed, or wild chamomile, resembles officinal chamomile in most of its qualities and uses, but its smell is different in being fetid, and its juice is capable of blistering the skin. Its rank odor and acrid qualities probably led to its being used as a nervous stimulant in such cases as those for which valerian is usually employed, and especially for the relief of flatulent *colic* and *dysmenorrhœa*. Its excitant properties adapted it to popular use as a sudorific and anti-spasmodic. The leaves are commonly applied externally, but an infusion of the flowers is preferable for internal use.

COTYLEDON.—NAVELWORT.

Pennywort, E.; *Cotylet*, *Nombril de Vénus*, Fr.; *Nabelkraut*, G.

Cotyledon Umbilicus, Linné, s. *Umbilicus pendulinus*, De Candolle.

Nat. Ord.—Crassulacæ.

Description.—A perennial herb of Southern and Western Europe, growing on rocks and old walls. It has a fleshy tuberous root and an erect stem about 6 inches (15 Cm.) high. The leaves are smooth, fleshy, peltate, concave, roundish, and repand-crenate, about 1 inch (25 Mm.) broad, the upper ones smaller, roundish, wedge-shaped, and on shorter petioles. The numerous small flowers are greenish-yellow and tubular, bell-shaped, with a five-parted corolla, ten stamens, and five many-ovuled ovaries. The dry plant is inodorous and has a mucilaginous taste.

Constituents.—Navelwort was analyzed by Hétet (1864) with the following results: The fresh plant contains 95 per cent. of water, 0.001 per cent. of salt of trimethylamine, the same quantity of ammonia salt, 0.9 per cent. nitrate of potassium, 2.063 per cent. of other salts, the remaining 2.035 per cent. being sugar, mucilage, starch, cellulose, etc.

Medical Action and Uses.—Between 1849 and 1855 several English practitioners abounded in eulogies of this plant as a remedy for *epilepsy*. They were, for the most part, gentlemen of good, and even of eminent, professional standing, and their opinions for a time led physicians astray; but when the medicine had been tried by experts both in England and upon the Continent, it was adjudged to be utterly worthless. Against this sentence there has been no appeal. Formerly the mucilaginous leaves of the plant were applied to *contusions*.

CREASOTUM, U. S., Br.—CREASOTE.

Kreosotum, P. G.; *Créosote*, Fr.; *Kreosot*, G.

A product of the distillation of wood-tar.

Origin and Preparation.—Creasote, which was discovered by Reichenbach (1830), is one of the numerous products resulting from the dry distillation of wood. According to Voelckel, it is not produced from cellulose, but rather from the incrusting layers of the wood-cells. Crude wood vinegar is stated to contain about 1 per cent., but beech-wood tar occasionally 25 per cent. of it; the latter is therefore the best material for its preparation. To obtain it the tar is distilled until about one-half is passed over and dense vapors of paraffin, etc. make their appearance. The distillate separates into a heavy and light oily layer, with an intervening aqueous stratum of an acid reaction. The light oil contains *eupion*. The heavy oil is treated with a concentrated solution of sodium carbonate, and the separated oily liquid is distilled, that portion of the distillate only being collected which is heavier than water. This distillate is treated with potassa solution spec. grav. 1.12, whereby the creasote is dissolved and *eupion* separated. The potassa solution is now supersaturated with sulphuric acid, and the precipitated creasote well washed with water and rectified, the product distilling at and above 203° C. (397° F.) being collected. The treatment with potassa and sulphuric acid is repeated until the potassium creasote solution does not turn brown on being heated in the air.

To obtain it from crude pyroligneous acid the oily constituents are first separated by saturating the crude acid with sodium sulphate at about 70° C. (158° F.), and while warm skimming off the supernatant layer. The cold thick oil is distilled, treated with sodium carbonate, and further purified as above.

Properties.—Creasote is a colorless oily liquid; age renders it slightly yellowish, but even exposure to direct sunlight should scarcely render it brown (*P. G.*); but the U. S. P. permits it to turn reddish-yellow or brown by exposure to light from the pres-

ence of tar-oils. It is very refractive to light, neutral to test-paper, of a peculiar penetrating smoky odor and of a caustic and burning taste. Its specific gravity is 1.035 to 1.085, *U. S.*, *P. G.*; 1.071 *Br.* It volatilizes without leaving any residue, begins to boil at about 200° C. (392° F.), *U. S.*, and most of it distils between 205° and 220° C. (401° and 428° F.). When cooled to -27° C. (-17° F.) (-20° C. = -4° F., *U. S.*, *P. G.*), it becomes thick, but does not solidify. It is inflammable and burns with a luminous and very sooty flame. With 120 parts of hot water it yields a clear solution, which on cooling becomes turbid and afterward clear again; with less water (80 parts of cold and 12 of boiling water, *U. S.*) turbid mixtures are obtained. The clear watery solution yields with bromine-water a red-brown resinous precipitate, and with a little ferric chloride a gray-green or transient blue color, which rapidly changes to dingy brown, the liquid becoming turbid and separating a flocculent precipitate (difference from carbolic acid). It takes up 50 per cent. of glycerin or 15 per cent. of ammonia sp. gr. 0.940, and is freely soluble in alcohol, ether, carbon bisulphide, glacial acetic acid, fixed and volatile oils. When agitated with an equal bulk of ammonia-water it separates unchanged on standing, but it dissolves in potassa solution, the liquid giving off creasote when heated to boiling. It causes precipitates with solutions of gum and albumen, but not with gelatin, and does not render collodion gelatinous (difference from carbolic acid). It preserves meat, probably in consequence of its behavior with albumen, and is present in the smoke of burning wood. Creasote is decomposed by strong nitric and sulphuric acids, and in contact with silver nitrate the latter is reduced.

Composition.—That creasote is a mixture of a number of different compounds has been long known, but their isolation has been a matter of great difficulty. In 1867, Gorup-Besanez recognized the presence of *guaiacol*, $C_7H_8O_2$, and *creosol*, $C_8H_{10}O_2$, in beechwood tar creasote; both are oily liquids of the general properties of creasote, the former boiling at 200° C. (392° F.), the latter between 220° and 224° C. (428° and 435° F.) (Tiemann and Koppe, 1881). Heated with hydriodic acid, both yield methyl iodide, and in addition thereto *pyrocatechin*, $C_6H_6O_2$, is produced by the former, and by the latter a non-crystallizing body isomeric with orcin, $C_7H_8O_2$. Tiemann and Mendelssohn (1876) proved also the presence of *phlorol*, $C_8H_{10}O$, which had been previously supposed to exist in it and in impure carbolic acid, the so-called *coal-tar creasote*. They dissolved the portion obtained by fractional distillation near 220° C. (428° F.) in ether, and added concentrated potassa solution, whereby its compound with creosol was separated, while the phlorol remained in the mother-liquor. Reimer observed (1876) that guaiacol, treated with chloroform and soda and afterward with an acid, is converted into *vanillin*, the aldehyd of *vanillic acid*, which latter was obtained from creosol by converting it first into acetyl-creosol and oxidizing this with potassium permanganate (Tiemann and Mendelssohn, 1877).

Besides the three principles named, others are likely to be present in creasote from different sources, such as *methyl-creosol*, $C_9H_{12}O$ (boiling-point 215° C. = 419° F.), and *methyl-guaiacol*, $C_8H_{10}O_2$ (boiling-point 205° C. = 401° F.). The cresols and phenols boiling below 200° C. (392° F.) should be absent (see pages 40, 42).

Tests.—For *distinguishing* between creasote and carbolic acid their behavior in aqueous solution to ferric chloride is decisive or their alcoholic solutions may be tested. On adding a strong solution of ferric chloride to a strong alcoholic solution of creasote, a blue and then a green color is produced; with a similar solution of carbolic acid the coloration will be at first blue, then brown, or, in certain proportions, green; if now six or eight times the bulk of water be added, the creasote mixture will become dingy-brown, with the separation of minute oily drops, but the carbolic acid mixture will remain perfectly transparent and acquire a beautiful blue color. J. Williams (1872) did not succeed in detecting with these reactions adulterations of creasote with carbolic acid. It is obvious that unfailling tests can hardly be expected for a variable mixture of compounds, some of which are still unknown; yet since guaiacol is the principal constituent of creasote, the tests for this principle are generally applicable, or rather the absence of the impurities which are likely to be present may be proven by the non-appearance of their characteristic reactions. Thus, the absence of *fixed oils* is shown by the complete volatility of the sample; a drop may be put upon bibulous paper, and this exposed to a temperature near 100° C. (212° F.), when the greasy stain should gradually completely disappear. "The absence of *tar-oils* is shown by caustic soda. If 1 part of creasote be agitated with 1 part of soda solution sp. gr. 1.16, a clear solution should result, which does not acquire a dark color, and on being largely diluted with water does not separate fetid tarry products (cresol, toluol, etc.)."—*P. G.* For the absence of *carbolic acid* the *U. S. P.* offers

two tests: 1, that it should not coagulate collodion; and 2, the glycerin test. The first test will not detect small quantities (5 to 10 per cent.) of carbolic acid. Morson (1872) proposed as a test for pure creasote its insolubility in glycerin, in which it becomes readily soluble on the addition of carbolic acid. The test was, however, soon proven to be unreliable for German beech-wood tar creasote, and to be applicable only to English pine-wood (Norway) tar creasote; and the cause was explained by Graetzel (1877) to be the presence in the latter of oil of turpentine derived from the tar; he suggests the approximate determination of the quantity of carbolic acid by the fractional distillation of the suspected creasote, or by combining it with saturated potassa solution and crystallizing from ether, when carbolic acid will be liberated from the mother-liquor by acidulating with sulphuric acid and distilling. A. H. Allen (1878) corroborated the insolubility in glycerin of Morson's creasote, which boiled at 217° C. (422.6° F.), and must therefore have been free from oil of turpentine; he regards the tests with glycerin and collodion as the only ones of service with mixtures of carbolic acid and creasote. The glycerin test is now formulated thus: "If 1 volume of creasote be mixed with 1 volume of glycerin, a clear mixture will result, from which the creasote will be separated by the addition of 3 or more volumes of water."—*U. S.* "Creasote should be almost insoluble in three times its volume of a mixture of 3 parts of glycerin and 1 part of water."—*P. G.* The last authority adds another test: "If 2 volumes of creasote be agitated with 20 volumes of ammonia-water, after separation of the mixture the creasote should measure not less than $1\frac{1}{2}$ volumes." Carbolic acid is completely soluble in 10 parts of ammonia, while creasote requires not less than 40 volumes for solution.

Fröhde's reagent, prepared by dissolving 1 part of molybdic acid in 100 parts of sulphuric acid, has been found by E. W. Davy (1878) to be a reliable test for detecting an admixture of carbolic acid in creasote, the former producing with the reagent a yellowish or brownish tint, passing into maroon or reddish-brown, and finally into beautiful purple; the latter causes a brown or reddish-brown color, which becomes fainter, and finally light yellowish-brown. The test is applied by adding 1 or 2 drops of the aqueous solution of the substance to 3 or 4 drops of the reagent; warming the mixture gently will hasten the production of the final coloration. If the creasote contains but a small quantity of carbolic acid, 10 drops of it are dissolved in $\frac{1}{2}$ ounce of water and the solution distilled. The first portion of the distillate will give the creasote reaction, and the last portions that of carbolic acid.

It should be stated that much of the commercial creasote is coal-tar creasote, and readily recognizable as such by its behavior to ferric chloride.

Off. Prep.—*Aqua creasoti*, *U. S.*; *Mistura creasoti*, *Unguentum creasoti*, *Vapor creasoti*, *Br.*

Physiological Action.*—*On Animals*: A small proportion of creasote is sufficient to cause plants to fade and wither, and it is equally fatal to the insect tribes. Given to animals, it excites inflammation of the stomach, pain, vomiting, salivation, laborious breathing, convulsions, and death. Injected into the veins, according to the dose and degree of its concentration it causes death by arresting the heart, or this result follows previous embarrassment of the breathing. These effects are due to its coagulating action on the blood.

On Man: Applied pure to a mucous membrane or to the raw cutis, it excites severe burning pain, coagulates the albumen of the secretion, and may even produce ulceration. Its taste is very penetrating and peculiar, and may be detected in a solution of 1 part of creasote in 1000 of water. In doses of 1 or 2 drops it causes burning in the throat and œsophagus. Larger medicinal doses, if continued, are apt to occasion a sort of intoxication, with giddiness, dullness, debility, frequent pulse, and dyspnœa. The urine is increased and blackened, and exhales the odor of the medicine; sometimes there is strangury. The vapor, when inhaled, is soporific. Applied externally to an ulcer, creasote has occasioned faintness, palpitation, etc. Excessive doses may cause severe abdominal pain and bloody stools. A case in which 2 drachms were taken ended fatally. Another case is reported in which an infant a year old is said to have taken a teaspoonful of creasote, and recovered after having exhibited great debility, pallor, a hoarse croupy cough, and stertorous breathing (*Grinnell, Med. News*, xl. 344). A fatal case occurring in an infant was remarkable for the severe lesions of the mouth, throat, etc. (*Edinb. Med. Jour.*, xxviii. 655).

* The almost complete substitution in commerce of carbolic acid for creasote, and the very close analogy in their operation, render a more detailed account of the latter unnecessary.

Medical Uses.—The first medicinal use of creasote was to check *vomiting* in cholera, and subsequently it was found to relieve this symptom produced by reflex irritation, by exhaustion in alcoholism, by sea-sickness, by Bright's disease, by malignant disease of the stomach, and by certain forms of dyspepsia, probably of the fermentative sort. Its manifest hæmostatic powers in external *hæmorrhage* led to its use in bleeding from the lungs, stomach, bowels, kidneys, bladder, and uterus, and its analogous operation was employed to correct excessive secretion in *diabetes, polyuria, and bronchorrhœa*. When creasote was first introduced it was vaunted as a remedy for pulmonary *phthisis*, but naturally fell into the same discredit as all other medicines for which this claim is made. It is, however, true that both by inhalation and by its internal administration it tends to reduce excessive bronchial secretion, and thereby prolong life, just as many other medicines and dietetic agents are known to do. If a solution of 2 or 3 drops of creasote in a fluidrachm of alcohol is diluted with 6 fluidrachms of water, it forms, when atomized, one of the best remedies for the symptoms in question. Administered by the stomach, it is less efficient, but still useful. It may be given with cod-liver oil in the dose of about 1 drop. Some have preferred it associated with tolu in lozenges (Reuss); others prescribe it simply dissolved in alcohol. The preceding remarks are equally applicable to *chronic bronchitis and laryngitis*; and, indeed, in pulmonary consumption the medicine can reach only the effects of the disease, not the essential organic cause of those effects. There is no better agent for the relief of *toothache* due to caries and inflammation of the dental pulp. For this purpose it should be applied upon a small and dense wad of cotton or lint. Creasote-water is sometimes used as an injection to cure *leucorrhœa and gleet*; it is an excellent application to *burns and chilblains* and to all forms of *ulcers* requiring stimulation, but especially to such as present flabby and bloody granulations and a fetid discharge, as in *cancer, gangrene, mercurial stomatitis, chronic glanders, azæna*, etc. It is a useful stimulant in certain cases of *deafness* due to dryness of the external auditory canal. The anti-putrescent power of this substance has caused it to be used to preserve dead animal matter for *dissection*, etc. Creasote has been given, like carbolic acid, for its anti-zymotic virtues in the treatment of *typhoid fever*, but, however it may seem to be theoretically fitted for the cure of that disease, its efficacy has not been generally admitted. Indeed, if it act in the manner supposed, its advantages are not very explicable when it is administered by enema, as Dujardin-Beaumetz advises. If given at all, it should be in the form of creasote-water, and by the mouth in the dose of a fluidrachm. It has been applied as a means of allaying *itching* in numerous diseases of the skin, but in a concentrated form it is more efficient in causing the shrivelling and destruction of *warts, condylomata, and navi materni*. If carbolic acid were not so universally used instead of creasote, it would still be preferable as having a less persistent and disagreeable smell. This may be removed from the body or clothing by chlorinated lotions. The poisonous effects of creasote may be combated with wine, coffee, and other stimulants.

The *dose* of creasote is 1 or 2 drops (Gm. 0.05–0.10). It may be given in pill or emulsion or in the form of creasote-water. It is rendered more miscible with water by the addition of an equal quantity of solution of potassa. Its taste may be disguised by aromatic waters. It may also be used by inhalation, dissolved in from 1 to 3 parts of rectified spirit.

CRETA PRÆPARATA, U. S., Br.—PREPARED CHALK.

Creta lavigata.—*Craie préparée, Craie lavée*, Fr.; *Präparirte Kreide, Schlammkreide*, G. Formula CaCO_3 . Molecular weight 100.

Native friable carbonate of calcium freed from most impurities by elutriation.

Origin.—Neither the U. S. nor the Br. Pharmacopœia now gives a process for the preparation of prepared chalk, but the last-named authority adds to the above definition that it is “afterward dried in small masses, which are usually of a conical form,” and, mainly for the purpose of producing carbonic acid gas, recognizes

CRETA, Br.; Chalk, E.; Crai, Fr.; Kreide, G.

Chalk is a mineral found in many parts of the world and very abundantly on the coasts of the English Channel. It consists mainly of the microscopic shells of Foraminifera, and, chemically, is carbonate of calcium, generally containing a little silica, aluminium, iron, magnesium, and organic matter. It is usually soft and earthy, but occasionally compact and rather hard, often of a yellowish-white, or even red, color, due to ferric oxide; as met with in commerce it is nearly white. Its specific gravity is about 2.5. It is much used for making marks which are readily effaced. Freed from the hard, silicious portions by

pulverization and diffusion in water, it constitutes *whiting*, and if prepared from very white and soft chalk it is known as *Spanish* or *Paris white* (Blanc d'Espagne, Blanc de Troyes, *Fr.*). The latter, mixed with coloring matters and moulded into pencils, forms the main ingredient in *pastil* colors. Being very rapidly and almost completely dissolved by hydrochloric acid, chalk is not adapted for generating a continuous stream of carbonic acid gas. To be suitable for medicinal purposes it requires to be purified or prepared.

Preparation.—Take of chalk a convenient quantity. Add a little water to the chalk and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and after a short interval decant into another vessel the supernatant liquid while yet turbid. Treat the coarser particles of chalk remaining in the first vessel in a similar manner, and add the turbid liquid to that previously decanted. Lastly, let the powder subside, and, having poured off the water, dry it.”—*U. S.* 1870.

The directions given here explain the *process of elutriation*, which consists in separating the finer and lighter from the coarser and heavier particles by suspending them in water, and, after the latter have subsided, pouring off the water, holding the former still in suspension, which are then allowed to subside. The powder, while still moist, is then often dried in the form of small nodules, which are usually made by putting the sediment, still moist, into a funnel-shaped vessel and depositing it in small quantities upon the surface prepared for it, either by striking the lower end of the funnel against it or by pushing the soft mass through the funnel-tube by the aid of a suitable rod. The surface used for drying is either glass or a smooth calcareous stone, the latter serving for the rapid absorption of the moisture; the dry powder adheres loosely in the form of small cones. The heavy portion, which subsided first, is again triturated, *levigated* with some water, and again subjected to elutriation.

Bismuth subcarbonate and subnitrate and other pulverulent mineral salts are sometimes dried in the same manner.

Properties and Tests.—Prepared chalk is in conical nodules, forming a white, amorphous, insipid powder, and, being nearly pure calcium carbonate, has all the physical properties of that compound (see page 350), except that the color is usually of a less bright tint, and that, viewed under the microscope, the particles do not present a crystalline appearance. The chemical behavior is likewise the same, except that on dissolving prepared chalk in diluted hydrochloric, nitric, or acetic acid a trifling insoluble residue is usually left, and that the rapid and copious effervescence of carbonic acid gas produces a more permanent foam. The solution should assume only a faint blue color on the addition of potassium ferrocyanide (iron), and when completely precipitated by ammonium carbonate the filtrate generally gives a turbidity on the addition of ammonium phosphate (magnesia). The Pharmacopœia also adds, for no obvious reasons, a test for the absence of strontium and barium (the acetic acid solution is not precipitated by calcium sulphate), but omits tests for other white mineral substances.

Substitution.—*Powdered gypsum*, calcium sulphate, has been during the past thirty years repeatedly sold in place of prepared chalk. It is of a whiter color, does not effervesce with acids, and yields with a large quantity of distilled water a neutral solution giving white precipitates with barium chloride and ammonium oxalate, the latter being soluble in diluted hydrochloric acid.

Off. Prep.—Hydrarg. cum cretâ. Mistura cretæ. *U. S. Br.*; Pulvis cretæ aromaticus, Pulv. cretæ arom. cum opio, *Br.*; Trochisci cretæ, *U. S.*

Allied Drugs.—1. CORALLIUM.—Coral, *E.*; Corail, *F.*; Koralle, *G.*—*Oculina virginea*, *Lamarck*, and *Corallium rubrum*, *Lamarck* (s. *Isis nobilis*, *Pallas*). Class, Polypiphera.—Corals are polypipherous animals inhabiting the sea, and consisting of a skeleton and a fleshy portion. Those which were formerly, and are still occasionally, employed in medicine have a calcareous skeleton which branches considerably, assuming the form of a tree or shrub, on the branches of which the individual animals are located in tube-like apertures. Of the numerous species which have been distinguished the skeletons of only two have been used. The first one mentioned above has a milk-white color, the second is of a dull-red. Besides a small quantity of organic matter, coral consists almost exclusively of carbonate of calcium, with a little carbonate of magnesium. The color of red coral is due to about 4.25 per cent. of ferric oxide.

2. LAPIDES (s. OCULI, s. CALCULI, s. LAPILLI) CANCRORUM.—Crabs' eyes, Crabs' stones, *E.*; Yeux (Pierres) d'écrevisses, *Fr.*; Krebsaugen, Krebssteine, *G.*—They are concretions contained in the stomach of the *crayfish*, *Astacus fluviatilis*, *Fabricius*, class Crustacea, and are obtained in Russia by allowing the animals to putrefy and washing the mass with water. They are circular, $\frac{1}{8}$ to $\frac{1}{2}$ inch (3 to 9 Mm.) in diameter, plano-convex, with a concentric groove on the flat side, consist of several layers, acquire in boiling water a rose-red color, and dissolve partly with

efflorescence in hydrochloric acid, leaving a cartilaginous mass of the shape of the crabs' stones. They contain about 63 per cent. of calcium carbonate and 17 per cent. of calcium phosphate, the remainder being various animal matters with small quantities of other salts. Facitious crabs' stones, which are sometimes met with, are completely dissolved or disintegrated by hydrochloric acid.

3. *OS SEPIÆ*.—Cuttlefish-bone. *E.*: Os de sèche, *Fr.*: Sepie, Weisses Fischbein, *G.*—It comes chiefly from the Mediterranean, from *Sepia officinalis*, *Linné*, class Cephalopoda, and is the calcareous bone contained in the mantle of the animal. It is oval-oblong in shape, both sides slightly convex, the rear surface being smooth, hard, and glossy, the remainder porous in texture and friable. It is of a white color, and consists of 80 to 85 per cent. of calcium carbonate, with traces of phosphates, 12 to 16 per cent. of animal matter, and about 4 per cent. of moisture.

4. *TESTA PRÆPARATA*, *U. S.* 1870; *CONCHÆ PRÆPARATÆ*, *P. G.* 1872.—Prepared oyster-shell, *E.*: Magistère de coquilles (d'écaillés) d'hûîtres, *Fr.*: Präparirte Austerschalen, *G.*—From the shell of *Ostrea edulis*, *Linné*. Class Acephala (Conchifera), ord. Lamellibranchia, Fam. Ostracea.—The oyster inhabits the Atlantic and Indian Oceans and adjacent seas in the neighborhood of the coasts, and is abundant in the bays and on the coast of North America. It consists of a soft, fleshy, suborbicular body, which is enclosed in a calcareous shell opening by two valves, the deeper one being adherent to the rock. Oysters are caught by dredging, and are often planted in creeks and rivers near the sea-shore. The flesh is a nutritious article of food, but the official parts of oysters are the shells. Oyster-shells are of an irregular shape, and vary between roundish, obovate, and oblong in outline. The lower valve is deeper than the upper one, which is nearly flat, the two being united by a toothless hinge. The shells are composed of imbricate foliaceous layers, are externally rough, uneven, and of a gray or brownish color, and have their internal surface smooth and white. The principal constituent of oyster-shells is carbonate of calcium, which, according to Schlossberger, varies in the different layers between 88 and 98 per cent., the pearly inner layer containing the largest quantity. The analyses of Bucholz and Brandes, Phipson (1860), How (1866), and others indicate that the organic matter present in oyster-shells may vary between 0.5 and 4.5 per cent. The remaining inorganic constituents are small amounts of phosphate and sulphate of calcium, magnesium, silica, oxide of iron, and alumina.

For medicinal use oyster-shell is freed from extraneous matter by washing it with boiling water, removing the colored external layer with a knife, and rubbing the clean white inner layer into a powder, either in a mortar or upon a slab by means of a muller; the finest powder is then separated from the coarser particles by elutriation, and dried like prepared chalk. It has a close resemblance to the latter, but is rather rough as compared with it when taken between the teeth, and under the microscope is seen to consist of minute irregular and angular but not crystalline fragments.

Coral, crabs' eyes, crabs' claws, etc. consist essentially of chalk or carbonate of lime, but their action is modified, and perhaps rendered somewhat gentler, by the animal matter which they contain. Powdered cuttlefish-bone is used as an ingredient of dentifrices on account of its hardness.

Medical Action and Uses.—These medicines are antacid and absorbent, and thereby astringent. Externally, they are applied as dusting powders to absorb and neutralize the cutaneous secretions and those of superficial ulcers, and to protect erythematous inflammations. An ointment made with chalk is sometimes used, but the combination in some degree defeats the purpose of the chalk. Internally, prepared chalk is in common use, and is a most valuable remedy for the cure or palliation of almost every form of diarrhœa, but especially of those forms in which the intestinal discharges are acid. As a rule, its use in these cases should be preceded by an evacuant to remove undigested food or other irritating substances. There is no better remedy for the premonitory diarrhœa of cholera than this simple preparation. It is usual to associate chalk with opiates and astringents; thus, to chalk mixture (*Mistura creta*) are added the tinctures of opium, kino, catechu, etc. Richter, in noticing the general substitution of mineral for animal preparations of lime, expresses a doubt of its expediency. Prepared chalk, he remarks, is by no means a substitute for cretaceous preparations derived from the animal kingdom, which contain phosphate as well as carbonate of lime, are more acceptable to the stomach in moderate doses, constipate less, and are more readily absorbed into the system. This writer ascribes a diaphoretic virtue to crabs' eyes, and alleges that they may produce urticaria, and that they tend to excite hæmorrhage. The latter qualities may perhaps be hypothetical, but the belief that the animal carbonates in general derange the stomach less than other cretaceous medicines, and are on that account preferable for infants and delicate persons generally, cannot, it is believed, be successfully controverted.

The dose of prepared chalk or of prepared oyster-shell is from 5 to 60 grains (Gm. 0.30–4.00), according as its antacid or its astringent operation is chiefly sought.

CROCUS, U. S., Br., P. G.—SAFFRON.

Stigmata croci.—*Safran*, Fr., G.

The stigmas (and part of the style, *Br.*) of *Crocus sativus*, *Linné*. Bentley and Trimen, *Med. Plants*, 274.

Nat. Ord.—Iridaceæ.

Origin.—The saffron-plant is indigenous to Oriental countries, probably from Greece and Asia Minor eastward to Persia; it has been cultivated from an early period, and grows spontaneously in some parts of Southern Europe. At the present time commerce is supplied with saffron chiefly from Spain (Alicante and Valencia) and France (Gatinais). It is also grown in Austria, and to a limited extent in some of the south-eastern counties of Pennsylvania. Asia Minor, Persia, Cashmere, and China are the principal countries which supply the Oriental regions with it. The plant has a depressed tuberous bulb or corm, which, in the latter part of summer or early in autumn, produces about nine grass-like, keeled, and dark-green leaves, and afterward a few pale-purplish, red-veined, six-lobed flowers with three stamens and a filiform style, which is whitish below, yellow above, and divided into three orange-red stigmas. In the year 1876–77, 17,006 pounds, and in the following year nearly 3000 pounds, of saffron were imported into the United States; the average for seven years is 7900 pounds.

Description.—Each stigma is 1 to 1½ inches (25 to 31 Mm.) long, flattish-tubular, almost filiform below, gradually enlarged above, slit on the inner side, and with several roundish teeth on the edge. The three stigmas are usually united, and occasionally are collected with a considerable portion of the yellow style. Dried saffron is flexible and tough, of a brownish-red or orange-brown color, somewhat unctuous to the touch, of a peculiar aromatic odor and a bitter, aromatic, and warm taste. It retains about 12½ per cent. of moisture, and after this is expelled becomes friable and more readily pulverizable. When chewed it tinges the saliva deep orange-yellow.

Cake-saffron is now not met with in commerce. In its loose condition it is sometimes called *hay-saffron*. Several varieties are distinguished. *Spanish saffron* is usually collected with considerable portions of the styles, which are easily distinguished by their yellow color. *French* or *Gatinais saffron* is mostly of a better quality. The handsome saffron collected in Austria is rarely if ever seen in our markets. The excellent saffron collected in Eastern Pennsylvania is known there as *American saffron*—a term which in other parts of the United States is used to designate the florets of *Carthamus tinctorius*. Heinisch (1866) calculated that 33 to 36 pounds of saffron may be raised to an acre, and found 300 stigmas to weigh 13 to 14 grains, which requires over 50,000 flowers to obtain a pound.

Constituents.—Saffron contains gum, albumen, wax, fat, about 1 per cent. of volatile oil, and coloring matter, called *polychroit*, or by some authors *crocin*. Weiss (1867) prepared polychroit, $C_{48}H_{60}O_{18}$, by exhausting saffron first with ether, afterward with water. The infusion is precipitated by strong alcohol, and the filtrate by ether. The precipitate contains a little sugar, is very deliquescent, and dries over sulphuric acid to a hard ruby-colored mass, which is inodorous, of a sweetish taste, readily soluble in water and dilute alcohol, slightly in absolute alcohol, and insoluble in ether and benzol. On being treated with dilute sulphuric acid in an atmosphere of hydrogen, polychroit is decomposed into a volatile oil having the composition of carvol, $C_{10}H_{14}O$, sugar, $C_6H_{12}O_6$, and *crocin*, $C_{16}H_{18}O_8$. The latter is a red powder insoluble in ether, scarcely soluble in water, and freely soluble in alcohol and diluted alkalis. Warm concentrated potassa evolves from it vapors of a pungent odor; concentrated sulphuric acid produces a deep-blue color, changing to violet and brown; nitric acid colors it green, then yellow and brown. The same colors are produced by sulphuric and nitric acids with polychroit. The volatile oil obtained by the decomposition of polychroit has the odor and general properties of the volatile oil obtained from saffron by distillation with water. Quadrat (1851) observed that polychroit (his *crocin*) yielded with concentrated solution of alkalis a neutral volatile oil which was lighter than water and had an odor distinct from saffron. Lagrange and Vogel (1811) obtained from saffron 7.5 (Aschöff (1818) 1.4 and Hagan 1.25) per cent. of

FIG. 86.

Crocus sativus, *Linné*: a, stigma, upper part, magnified four diameters; b, style with stigmas; c, papillose margin of stigma, magnified 120 diameters.

volatile oil; the first result must have been mostly the volatile oil formed from the polychoit. Saffron yields about 5 per cent. of ash.

Adulterations.—The occasional admixture in true saffron of considerable portions of the yellow style has been noticed above. The appearance of inferior saffron is sometimes improved by oil or by glycerin; it then leaves a greasy stain on being slightly pressed between paper. Partially exhausted (mixed with good) saffron is recognized by the lighter and more uniform color of the stigmas. The tubular florets of *Carthamus* are easily distinguished by their five-toothed corolla and the projecting anthers with style. The styles of crocus, suitably dyed, have appeared in commerce as *feminelle*, a name also given to the dyed ligulate florets of *Calendula officinalis*, *Linne*; the latter are strap-shaped, with a three-toothed margin, and are easily distinguished from true saffron after soaking in water, or in dilute ammonia should the coloring matter of the dye be insoluble in water. The cut petals of the pomegranate, and the stamens of crocus and perhaps other flowers, are by the same means easily recognized from their different shape. About 1860, and again since 1870, Spanish (Alicante) saffron has often appeared adulterated with chalk, gypsum, or heavy spar, the powders having been rendered glutinous by some honey and mixed with the saffron; they then become yellowish and of the appearance of pollen. Powdered emery is said to be used in the same manner. The amount of such adulteration is sometimes 20 per cent., and may be estimated by incineration. The adulteration is detected without difficulty by throwing a pinch upon water, when the mineral matter will subside, and may be identified by appropriate tests. "If 1 part of saffron be macerated in 10 parts of water, a yellow-red liquid is obtained free from sweet taste, and which, diluted with 10,000 parts of water, has a distinct yellow color. Saffron on being dried at 100° C. (212° F.) should lose less than 14 per cent. of moisture, and on being now incinerated should leave not over 8 per cent. of ash."—*P. G.* These two tests will probably answer for determining the genuineness of saffron. The first, based on its tinctorial power, requires that 22 fluidounces of water be colored yellow by 1 grain of saffron; a single grain of saffron rubbed to a fine powder with sugar will impart a distinct tint of yellow to 700,000 grains (10 galls., *Br.*, or 12 galls., *U. S.*) of water (*Pharmacographia*).

An article has sometimes (1872) been offered as *African saffron*; it is mostly safflower, but occasionally it consisted of the corolla of *Lyperia crocea*, *Ecklon*, a scrophulariaceous plant indigenous to Southern Africa.

Pharmaceutical Preparations.—*SYRUPUS CROCI*.—Syrup of saffron.—25 parts of saffron are exhausted with sufficient Malaga wine to obtain 440 parts of tincture in which 560 parts of sugar are dissolved.—*F. Cod.*

Saffron is used only for *Tinctura croci*, *U. S.*, but enters into the composition of the following: *Decoct. aloes comp.*, *Pil. aloes et myrrhæ*, *Pulv. cretæ arom.*, *Tinct. cinchonæ comp.*, *Tinct. croci*, *Tinct. opii ammon.*, *Tinct. rhei*, *Br.*

Allied Drugs.—*GARDENIA GRANDIFLORA*, *Lourcero*, *G. FLORIDA*, *Linne*, and *G. RADICANS*, *Thunberg*.—*Nat. ord. Rubiaceæ*.—These shrubs are indigenous to Eastern and Southern Asia, and produce obconical four- or six-sided somewhat winged berries, which attain a length of $1\frac{1}{2}$ inches (4 Cm.) and contain numerous flat and finely-pitted seeds imbedded in a red pulp. The coloring matter of the latter, according to Rochleder and L. Mayer (1858), is identical with that of *Crocus*. The fruits are regarded as possessing demulcent and refrigerant properties, and are largely used in the East for dyeing yellow.

Medical Action and Uses.—Saffron is generally regarded as a stimulant aromatic. Like other powerfully odorous vegetable substances, its emanations occasion headache, sleep, stupor, and even death. It also displays anodyne and anti-spasmodic properties. Its aromatic quality is exhibited in its general use as a condiment in tropical countries, where the heat enfeebles digestion and vegetable food is chiefly used. Like other agents of its class, it sometimes appears to stimulate the pelvic organs, as shown by its employment from remote periods as an emmenagogue and also as an aphrodisiac. During its use the urine is colored yellow.

As just indicated, it is most commonly employed to prevent or relieve flatulent *dyspepsia* and its accompanying *colic*, for by expelling the gaseous contents of the digestive canal it enables that organ to perform its functions more perfectly. It may be prescribed, like other aromatics, to allay the pain of *dysmenorrhœa*. Hot infusions of saffron are sometimes given to promote *exanthematous eruptions*. It has long been reported to be efficacious in spasmodic *coughs* and *asthma*, but its value in these affections is very slight. Yet the preparations of saffron may be conveniently employed as vehicles for more powerful drugs. Like the flowers of other plants containing a volatile oil, those of saffron

have long entered into various compounds in popular use to relieve *rheumatic* and *neuralgic* pains, to remove the soreness and discoloration of *bruises*, and to promote the healing of *abrasions* and superficial sores. A collyrium of saffron has been employed in subacute and chronic inflammations of the *conjunctiva*, and saffron ointment has been reputed to be an excellent palliative of *hæmorrhoids*. A strong infusion of saffron applied to the gums is said to allay the pain of *dentition*.

Saffron has been omitted from most of the official preparations into which it formerly entered—a change justifiable, if at all, upon economical rather than upon medical grounds.

The dose of saffron is from 5 to 30 grains (Gm. 0.30–2.00), the former quantity sufficing as a gastric, the latter as a general, stimulant. But the dose should be repeated at short intervals. Only pure and well-preserved specimens can be depended upon. An infusion may be made with 2 drachms (Gm. 8) of saffron to a pint of boiling water, of which 4 ounces may be given at intervals of half an hour or an hour.

CUBEBA, U. S., Br.—CUBEB.

Cubebæ, P. G.; *Fructus* (s. *Baccæ*) *cubebæ*, *Piper caudatum*.—*Cubebæ*, E.; *Cubébe*, *Poivre à queue*, Fr.; *Kubeben*, G.

The unripe fruit of *Cubeba officinalis*, *Miquel*, s. *Piper Cubeba*, *Linneæ filius*. Steph. and Church, *Med. Bot.*, plate 175; Bentley and Trimen, *Med. Plants*, 243.

Origin.—The cubeb-plant, which is indigenous to Java and some of the adjacent islands, is a climbing dioecious shrub about 20 feet (6 M.) high, with ovate or ovate-lanceolate, leathery, and shining leaves upon short petioles about as long as the peduncles of the spikes. The pistillate spikes are about $1\frac{3}{4}$ inches (4 Cm.) long, cylindrical, with the fruit at first sessile, afterward stalked. The plant is cultivated chiefly in coffee-plantations, and the fruit collected before it is ripe. The importation of cubebs into the United States amounted in 1878 to 7045 pounds, reached 277,422 pounds in 1879, and averaged in 1882, for seven years, 167,290 pounds.

Description.—Cubebs are of the size and general appearance of black pepper, about $\frac{1}{8}$ or $\frac{1}{4}$ inch (4 or 5 Mm.) in diameter, at the base contracted into a kind of stalk $\frac{1}{8}$ or $\frac{2}{8}$ inch (8 or 10 Mm.) long, very slightly pointed at the apex from the remnants of the stigmas, of a brown-gray to blackish-gray color, and a reticulately wrinkled surface. The integuments of the fruit consist of a thin, dried, fleshy layer and a smooth lighter-colored shell, surrounding a globular cavity with an undeveloped whitish seed at the base. The epicarp and endocarp consist of stone-cells, those of the former being cubical in one interrupted row, those of the latter radially elongated and in two or three rows. The mesocarp is formed of thin-walled parenchyma and larger oil-cells, both containing crystals of cubebin, the former also starch-granules in the outer layer. The fruit has a strong spicy odor and a pungent aromatic and bitterish taste, is very frequently mixed with, and should be freed from, the nearly inodorous rachis or common axis, which is from 1 to $1\frac{3}{8}$ inches (25 to 40 Mm.) long and has a pitted surface.

Constituents.—Cubebs contain from 5 to 15 per cent. of volatile oil (see *OLEUM CUBEBAE*), fixed oil, waxy matter, resin, cubebin, gum, malates, etc. The medicinally most important constituents are the *indifferent resin* and *cubebic acid*; they were isolated by Bernatzik (1863), and further examined by E. A. Schmidt (1870, 1873). *Cubeb resin* is slightly soluble in ether, carbon bisulphide, or chloroform, but dissolves freely in caustic alkalis and alcohol; it is not precipitated from the spirituous solution by acetate of lead. *Cubebic acid*, $C_{14}H_{16}O_4$, is an amorphous yellowish mass, soluble in ether, chloroform, carbon bisulphide, benzol, and petroleum benzin, and is precipitated from its alcoholic solution by lead acetate; its sodium salt crystallizes from hot alkaline liquids and

Cubeba officinalis, *Miquel*.

FIG. 87.

from alcohol. Both resinous compounds are colored red by sulphuric acid. The indifferent resin has been obtained in quantities of 2.5 to 3.5 per cent., and the cubebic acid in amounts of 0.96 to 3.4 per cent.

Cubebin, $C_{10}H_{10}H_2$, according to Weidel (1877), was first obtained pure by Soubeiran and Capitaine (1839), and forms the principal portion of the deposit in the ethereal extract. It crystallizes in tasteless and inodorous white needles or pearly scales, which melt at 128° C. (257° F.), are colored red by sulphuric acid, and dissolve in 26.6 parts of ether, readily in benzol and in chloroform, and in 30 parts of cold and in 10 parts of boiling alcohol; the alcoholic solution has a bitter taste. By melted potassa cubebin yields carbonic, acetic, and protocatechuic acids. Medicinally, it appears to be inactive; its percentage varies between 0.4 and 2.5.

Potassium chloride has been found among the saline constituents of cubebs.

Impurities and Substitutions.—The presence of cubeb-stems (the rachis) has been alluded to before. Black pepper and other piperaceous fruits occur sometimes as accidental, rarely if ever as intentional, impurities. The fruit of *Rhamnus catharticus* has only a very superficial resemblance, and is at once distinguished by the true pedicel and its four seeds. Allspice is much larger, has no pedicel, contains two seeds, and is crowned with the calyx limb.

The following two species are mentioned in *Pharmacographia* as yielding fruits extremely cubeb-like: *Cubeba* Lowong, *Miquel* (Piper Lowong, *Blume*), and *Cub.* Wallichii, *Miquel* (Pip. ribesioides, *Wallich*). The fruit of *Cub.* canina, *Miquel* (Pip. caninum, *Dietrich*), is smaller than cubeb, and contracted below into a stalk of only half the length of the globular portion. In 1863 a fruit was sold as cubeb which by Græne-wegen was referred to *Piper anisatum*, *Humboldt et Bonpland*; it is probably the same which Flückiger and Hanbury refer to *Cubeba crassipes*, *Miquel* (Pip. crassipes, *Korthals*). The fruit of *Cub.* Clusii, *Miquel*, of Western Africa, resembles cubeb, but, according to Stenhouse (1855), it contains piperine instead of cubebin.

Off. Prep.—Cubebs are used for the distillation of *Oleum cubebæ*, and for the preparation of *Extract. cubebæ fluid.*, *Oleoresina cubebæ*, *U. S.*, and *Tinctura cubebæ*, *U. S.*, *Br.*

Physiological Action.—Cubeb is a local irritant. Taken into the stomach, it stimulates the whole intestinal tract, after the manner of black pepper, thereby exciting more or less irritation of the rectum and other pelvic organs. At the same time, its active principle is absorbed, causing flushing of the face and diffused warmth, and increasing the urinary secretion as well as giving it a peculiar odor. It does not derange the digestion like copaiva. Its direct and indirect operation upon the genito-urinary apparatus may be attended with painful irritation of those parts if the medicine is given when they are actively inflamed. Excessive doses may occasion vomiting, gastro-intestinal irritation, and a general feverish condition. Cubeb sometimes produces an erythematous eruption on the skin.

Medical Uses.—The chief medicinal application of cubeb is to relieve inflammation of the urinary passages. It has long been used for the cure of *gonorrhœa*, but at present, like copaiva, it is in a great degree superseded by the local treatment of that affection. In efficacy it is inferior to copaiva, but it is more readily tolerated by the digestive organs. The cases of gonorrhœa to which it is most appropriate are those in which the attack is recent and the inflammation moderate, but more inflammatory conditions, accompanied by chordee, scalding urine, and even swelled testicle, do not contraindicate the medicine, although they call for caution in its use—that is to say, for the administration of small rather than large doses. The former may be represented by about 15 grains (Gm. 1) three times a day; the latter, which usually should be reached by gradual increase, may be stated to be $\frac{1}{2}$ drachm (Gm. 2) or more. Few persons can long tolerate so large a dose, which is apt to cause vomiting and diarrhœa, besides inspiring invincible disgust. It should not be continued longer than a week or ten days, unless the gonorrhœal discharge declines, in which case the dose should be gradually reduced. It is asserted that the efficient element of cubeb in the cure of gonorrhœa is cubebic acid, which appears capable of curing the acute affection when given in doses of 2 or 3 grains (Gm. 0.10–0.15) every 2 or 3 hours; but, on the whole, it seems to be less successful than cubeb itself.

Irritability of the urethra in females, with accompanying vesical tenesmus and scalding of the urine—a condition often associated with catamenial congestion—is apt to be mitigated by cubeb in doses of from 20 to 30 grains two or three times a day. *Vesical irritability* and *tenesmus* produced by cold or by cantharidal irritation, and nocturnal inconti-

nence of urine, may often be cured in the same manner. Chronic *cystitis* and *vaginal discharges* are favorably influenced by cubeb, and, like *copaiva*, but less surely, this medicine may be of use in *chronic bronchitis*. Its local stimulant action seems to have been advantageous in certain cases of *pseudo-membranous angina*, when cubeb was given finely powdered in the dose of 2 or 3 drachms (Gm. 8–12), mixed with syrup. It was also administered with powdered sugar, which itself was probably not without influence on the result. But, while stimulating the fauces and the system generally, it also prevented the meddlesome medication which has not a little to answer for in this disease. Cubeb has been thought to be efficacious in certain nervous disorders, comprising *head-ache*, *vertigo*, *fainting*, *impaired memory*, and even *paralysis*; doubtless, such symptoms, depending upon exhaustion of the nervous centres, may be ameliorated by whatever stimulates them primarily, while it secondarily improves the digestion, and therefore the composition of the blood.

Cubeb is administered in doses of 10 grains (Gm. 0.60) and upward, either mixed with water or with powdered sugar or enclosed in wafers. In the last case it should be followed by a mouthful of water.

CUCUMIS.—CUCUMBER.

Concombre, Fr.; *Gurke*, G.

The fruit and seed of *Cucumis sativus*, Linné.

Nat. Ord.—Cucurbitaceæ.

Origin.—The cucumber is indigenous to Southern and Central Asia, but is now extensively cultivated in most civilized countries. It has a roundish hispid stem, climbing by simple tendrils, alternate, heart-shaped, and somewhat five-lobed rough leaves, and unisexual yellow flowers.

Description.—THE FRUIT is at first rough and somewhat verrucose, but becomes smooth on ripening. It is cylindrical-oblong, somewhat triangular, obtuse at both ends, sometimes curved, and varies considerably in size and color. It has a slight but quite characteristic odor and a slightly saline and rather harsh taste.

THE SEEDS are about $\frac{1}{2}$ inch (8 Mm.) long, oblong-ovate, flat, rather acute on the edge, and with a short point above. They are white, inodorous, and of an oily taste. The embryo is of the shape of the seed, and consists of two plano-convex white cotyledons, with a short radicle in the pointed end. The seeds contain about 30 per cent. of a bland light-yellow fixed oil.

Pharmaceutical Uses.—Prof. Procter (1853) gave a formula for *cucumber ointment*, which is prepared by grating 7 pounds of green cucumbers, expressing the juice, and incorporating it, about one-third at a time, with 15 ounces of suet and 24 ounces of lard, the fats having been previously fused together and allowed to cool until the mixture commences to thicken. After all the juice has been in contact with the fat, the latter is melted, strained, and preserved in glass jars covered with a layer of rose-water; the jars should be well closed. When intended for use a portion of the ointment is triturated with a little rose-water until it becomes white and creamy.

Allied Plants.—The following plants are indigenous to Southern Asia, and at present cultivated in many warm countries:

CUCUMIS MELO, Linné.—Muskmelon.—The seeds resemble cucumber-seeds, but are somewhat larger and rather more blunt on the edge; they contain an inodorous yellowish fixed oil.

CUCUMIS (CUCURBITA, Linné) CITRULLUS, Seringe, s. Citrullus vulgaris, Schrader.—Watermelon.—The seeds are about $\frac{1}{2}$ inch (12 Mm.) long, blackish or brown and marbled, broadly ovate, flat, blunt on the edge, near the pointed end with two thin converging ridges. They yield by pressure about 30 per cent. of a thin light yellow bland oil.

LAGENARIA VULGARIS, Seringe, s. Cucurbita Lagenaria, Linné.—Gourd.—The seeds are $\frac{3}{4}$ inch (18 Mm.) long, oblong, obtuse at both ends, thickened and with two furrows near the margin, the surface yellowish-white and soft felt-like.

MOMORDICA BALSAMINA, Linné.—Balsam-apple.—The fruit is ovate in shape, narrowed at both ends, somewhat angular, warty, bright-red or orange-colored, and separating laterally. It contains numerous flat, oval, and wrinkled brownish seeds, which are surrounded with a fleshy red arillus.

Medical Action and Uses.—The ointment prepared with cucumber-juice is supposed to be peculiarly mild, emollient, and healing when freshly made and applied to *abrasions* and other analogous lesions.

The juice of the watermelon increases somewhat the secretion of urine—an effect which is perhaps due to the sugar it contains. An infusion of the whole seeds is decid-

edly diuretic, and that of the bruised seeds is also demulcent. No better drink than the latter infusion can be used in all cases of irritation of the *kidneys* or *bladder*, and especially in those of *retention of urine* produced by cold.

The root as well as the fruit of *balsam-apple* is an active purgative. 2 drachms of the latter given to a dog are said to have killed it within 16 hours. In the Philippine Islands a decoction of it is employed as an emetic. An infusion of the seeds in olive or almond oil has been used as a vulnerary and also to relieve hæmoptysis (Strumpf, *Handbuch*, ii. 214).

CUMINUM.—CUMIN.

Fructus cumini s. cymini.—Cumin, Fr.; Kreuzkümmel, Mutterkümmel, Römischer (langer, scharfer) Kümmel, G.

The fruit of *Cuminum Cyminum*, Linné.

Nat. Ord.—Umbelliferae, Orthospermae.

Origin.—The cumin-plant is indigenous to Egypt and other parts of Africa, and is cultivated in various parts of Asia and Europe, in the latter continent chiefly in Southern Italy and the neighboring islands. It is an annual about 1 foot (30 Cm.) high; the leaves are divided into narrow linear segments; the umbels are small, and the umbellets have about five white or purplish flowers. 20.874 pounds of cumin-fruit were imported into the United States in the year 1866–67.

Description.—The fruit is about $\frac{1}{4}$ inch (6 Mm.) long, oblong, narrowed at both ends, slightly compressed laterally, and of a yellowish-brown color. The two mericarps are usually united; each has five light-colored filiform ribs, which are beset with soft short hairs and are separated by broad brown furrows, each containing a pale-brown rather broad, rough, hairy, secondary rib and covering one oil-tube. Two oil-tubes (vittæ) are contained on the face or six in each mericarp. The strong aromatic odor and taste somewhat resemble those of caraway. Cumin is very prone to the attacks of insects, which eat the entire seed, leaving only the fruit-shell.

FIG. 88.

Cumin: fruit and longitudinal section, 3 diameters: transverse section, 8 diameters.

Constituents.—Examined by Bley (1829), cumin was found to contain 7.7 per cent. of fat, 13.5 of resin, 15.5 of protein compounds, 8 of gum, and only 0.24 of volatile oil, the remainder being extractive, salts (mainly malates), cellulose, and 9 per cent. of moisture. Raybaud obtained nearly 3 per cent. of volatile oil. The latter consists of several hydrocarbons—one having the composition $C_{10}H_{16}$, another being *cymol* or *cymene*, $C_{10}H_{14}$, which at $15^{\circ} C.$ ($59^{\circ} F.$) has the specific gravity 0.860, boils at $175^{\circ} C.$ ($347^{\circ} F.$), and has a lemon-like odor (Gerhardt and Calours)—and of an oxygenated body, *cuminol* or *cumin-aldehyd*, $C_{10}H_{12}O$, which has the density 0.972, boils at about $230^{\circ} C.$ ($446^{\circ} F.$), has a caraway-like odor, and yields with nitric acid crystallizable *cuminic acid*, $C_{10}H_{12}O_2$. Volatile oils identical with *oil of cumin* have been obtained by Trapp (1858) from the fruit of *Cicuta virosa*, Linné, and by Haines (1856) from the fruit of *Ptychotis* (Carum, Bentley) Ajowan, De Candolle; the latter, however, was shown by Stenhouse to contain thymol.

The *ajowan* (Bentley and Trimen, *Med. Plants*, 120) is largely cultivated in Oriental countries; the fruit is about $\frac{1}{16}$ inch (1.5 Mm.) long, ovate, laterally flattened, rough, gray-brown, has broad ribs, and in each mericarp six oil-tubes.

Medical Action and Uses.—Cumin is mildly stimulant and carminative, in the same manner as anise and caraway, and may be used for the same purposes. It has been regarded as a galactagogue, but Dolan failed to detect any such action in it (*Practitioner*, xxvii. 164). It is, however, very seldom employed. The *dose* may be stated at from 15 to 30 grains (Gm. 1–2).

CUPRI ACETAS, U. S.—ACETATE OF COPPER.

Cuprum aceticum, *Acetas cupricus*, *Ærugo crystallisata s. destillata*, *Flores virides aëris*.—Copper verditer, Crystallized verdigris, E.; Acétate de cuivre, Verdet cristallisé, Crystaux de Vénus, Fr.; Kupferacetat, Gereinigter (krystallisirter, destillirter) Grünspan, G.

Formula $Cu(C_2H_3O_2)_2 \cdot H_2O$. Molecular weight 199.2.

Origin.—Verdigris was already known to Theophrastus about 300 B. C., when it was prepared from copper and various refuse products obtained in making wine. Crystallized copper acetate was probably first prepared by the Arabian chemists in the eighth

century by dissolving verdigris in vinegar. At present it is manufactured in the same manner, or from copper sulphate and lead or calcium acetate. The average annual importation of this salt into the United States was 592 pounds up to 1881.

Preparation.—Verdigris is dissolved in about 4 parts of warm wood vinegar; the clear decanted liquid is concentrated by evaporation in copper vessels and allowed to crystallize in wooden tanks; or, solutions of 2 parts of copper sulphate and 3 parts of lead acetate are mixed, the liquid decanted from the insoluble lead sulphate, acidulated with a little acetic acid, and evaporated to crystallize.

Properties.—This salt is met with in deep blue-green rhombic prisms, which are nearly opaque or somewhat translucent, glossy, superficially efflorescent on exposure to the atmosphere, and have the spec. grav. 1.914, an acetous odor, and a disagreeable metallic taste. The effloresced surface is dull and of a light bluish-green color, the powdered crystals of a bright blue-green, resembling verdigris. When kept over sulphuric acid the crystals turn white from the loss of water, but become blue-green again in the air. On the application of heat water is given off, and at 110° C. (230° F.) also traces of acetic acid, the loss in weight up to 140° C. (284° F.) amounting to about 10 per cent.; the water of crystallization is 9.04 per cent. The residue left is of a blue-green color, soluble in water, and on being heated to between 240° and 260° C. (464° and 500° F.) yields about 36 per cent. of glacial acetic acid, and above 270° C. (518° F.) acetone, carbonic acid gas, and other products of decomposition, while chiefly metallic copper is left behind. The salt dissolves at 15° C. (59° F.) in 13.4 parts (15 parts, *U. S.*) of water and in 135 parts of alcohol, and at the boiling temperature in 5 parts of water and in 14 parts of alcohol. The aqueous solution is blue-green, gives off acetic acid on boiling, depositing at the same time a basic salt, and changes to a deep-blue color with excess of ammonia or ammonium carbonate. Sulphuric and other strong acids decompose the salt, liberating acetic acid.

Tests.—The salt should be completely soluble in excess of solution of ammonium carbonate (absence of lead, calcium, etc.). If dissolved in diluted nitric acid, no precipitate should be produced with silver nitrate or barium nitrate (absence of chloride and sulphate). "If the aqueous solution of the salt be treated with hydrosulphuric acid until all the copper is precipitated, the filtrate should leave no residue on evaporation (alkalies, alkaline earths, and iron). If the aqueous solution be heated to boiling with solution of soda in excess, it yields a filtrate which should not be clouded by hydrosulphuric acid (absence of lead, zinc)."—*U. S.*

Pharmaceutical Preparation.—TINCTURA CUPRI ACETICI RADEMACHERI. Dissolve 1 part of acetate of copper in 10 parts of warm water, and add 8 parts of alcohol.

Allied Salt.—CUPRI SUBACETAS, *U. S.* (1870); *Erugo*, *Viride aëris*, *Subacetas cupricus*.—Verdigris, Subacetate of copper, *E.*: Acétate basique de cuivre, Vert-de-gris, *Verdet gris*, *Fr.*: Grünspan, Spangrün, Basichessigsäures Kupfer (Kupferoxyd), *G.*—Formula of pure verdigris (Cu_2O) $2\text{C}_2\text{H}_3\text{O}_2$. Molecular weight 261.—In the wine districts of Southern Europe, and particularly in the neighborhood of Montpellier, verdigris is prepared by the aid of the mare of the wine-press. These grape-husks are allowed to undergo the acetic fermentation, and are then stratified in earthen vessels with sheets of copper, which, if new, have been previously superficially corroded by a solution of acetate of copper. After having been thus kept at a temperature of 8° or 10° C. (46° or 50° F.) for 3 or 4 weeks, the plates are removed, placed upright to dry, and for the following 6 or 8 weeks are occasionally dipped into water and exposed, until the neutral acetate at first formed has been converted into a thick layer of verdigris, which is scraped off. The sheets are then replaced in the grape-husks, and the process repeated until the copper has been completely corroded. The scrapings are formed with water into cakes of convenient size and dried. Verdigris of inferior quality is said to be made in the cider districts of England in a similar manner from pommage or apple-mare, and in some places it is obtained by exposing the copper to the vapors of vinegar or pyroligneous acid or by treating impure cupric oxide with the latter. The annual importation of verdigris into the United States during seven years averages about 203,902 pounds; in 1880 it reached 305,792 pounds. Verdigris is met with in commerce in heavy and hard bluish-green masses containing a considerable number of small crystals and breaking with an earthy somewhat crystalline fracture. It varies in composition, but always consists mainly of hydrated oxyacetate of copper, and contains between 45 and 50 per cent. of cupric oxide. It is decomposed by, and but partially soluble in, water, insoluble in alcohol, but completely soluble, the impurities excepted, in ammonia and dilute sulphuric, acetic, and hydrochloric acids. Acids should produce but little effervescence, showing the absence of

FIG. 89.

Crystal of Copper
Acetate.

carbonate. The presence of chalk as an impurity is determined by the copious effervescence when dissolving a sample in warm acetic acid, and by the precipitate occurring in the solution on the addition of ammonium oxalate.

Medical Uses.—Acetate of copper has been used in collyria and in lotions for various local inflammations, including *gonorrhœa*, in solutions of $\frac{1}{2}$ to 1 per cent., and internally, in pill or potion in doses of $\frac{1}{4}$ to 1 grain, in several chronic *skin diseases*, *intermittent fever*, and *epilepsy*; but in the latter affection it is now quite obsolete, and in the former is superseded by the sulphate. Acetate of copper has been employed, like acetate of zinc, in collyria and for stimulating aphthous ulcers of the mouth.

Subacetate of copper is very rarely used internally, and seldom as a local application. Its stimulant or escharotic action, according to the strength of the solution employed, is sometimes taken advantage of in the treatment of indolent *ulcers* and chronic tuberculated affections of the *skin*, and to remove condylomata and *warts*, especially the soft warts due to *sypilis*. These excrescences, and also condylomata, may be destroyed by a mixture of equal parts of verdigris and powdered savine.

CUPRI SULPHAS, U. S., Br.—SULPHATE OF COPPER.

Cuprum sulfuricum, P. G.; *Sulfas cupricus*, *Cuprum vitriolatum*.—*Blue vitriol*, *Blue-stone*, E.; *Vitriol bleu*, *Sulfate de cuivre*, Fr.; *Kupfervitriol*, *Blauer Vitriol*, *Schwefelsaures Kupfer* (*Kupferoxyd*), G.

Formula $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. Molecular weight 249.2.

Preparation.—Blue vitriol is obtained on a large scale from the native (*copper pyrites*) or artificially-prepared sulphide by converting it through oxidation into the sulphate; for this purpose the sulphide is obtained by heating sheet copper to redness and throwing sulphur upon it. The water accumulating in copper-mines contains the sulphate in solution, formed by the oxidation of the native sulphide. The iron contained in this is removed either by digesting with oxide or carbonate of copper or by evaporating to dryness and heating until the iron salt is decomposed. The same salt is also formed in the preparation of sulphurous acid from copper and hot oil of vitriol, and in the extraction or purification of silver by precipitating this metal from its sulphuric acid solution by means of copper; also by dissolving the black scales obtained in coppersmithing in weak sulphuric acid (chamber acid). 190,657 pounds of sulphate of copper were imported into the United States in 1876–77; this amount has gradually decreased to 20 pounds in 1881 and 1882.

Purification.—Sulphate of copper cannot by recrystallization be separated from the sulphates of the allied and of the alkaline metals, owing to the formation of double salts. The so-called *double vitriol* (vitriol de Salzbourg, Fr.; *Doppelvitriol*, G.) contains 70 to 80 per cent. of ferrous sulphate, and the *vitriol mixte de Chypre* contains zinc sulphate; these were formerly, but now are rarely, employed in the arts. If iron alone is present, it may be conveniently removed by oxidizing with nitric acid and digesting the solution with barium carbonate; ferric hydrate and barium sulphate will be precipitated with the excess of the carbonate, and the filtrate will yield pure crystals. If contaminated with other metals its purification will be difficult, and it is more convenient to prepare the salt directly by heating 3 parts of copper with 10 parts of sulphuric acid, or with 5 parts of sulphuric acid, 50 of water, and 4 or 5 of nitric acid.

Properties.—Sulphate of copper crystallizes in transparent azure-blue oblique triclinic short prisms, which are without odor, and have a disagreeable styptic metallic taste.

the specific gravity 2.274, and an acid reaction. On trituration they yield a whitish-blue powder; on exposure to a dry atmosphere they effloresce superficially, gradually part with $4\text{H}_2\text{O}$, or 28.86 per cent. of water, at a temperature of 100°C . (212°F .), and when heated to between 220° and 240°C . (428° and 464°F .) lose all their water of crystallization, amounting to 36.07 per cent., leaving a whitish, friable mass of the anhydrous salt, which in a damp atmosphere again combines with water and becomes blue and crystalline, but at a strong red heat is decomposed into oxygen, sulphurous and sulphuric anhydrides, and black cupric oxide. The salt is insoluble in alcohol, but dissolves in 400 parts of diluted alcohol sp. grav. .940. 1 part of the crystallized salt dissolves

FIG. 90.

Crystal of Copper Sulphate.

At 10°	20°	30°	40°	60°	80°	100°	104° C.
in 2.71	2.36	2.07	1.76	1.29	.85	.55	.47 parts water.

The solution has a pale-blue color, which is changed to green on the addition of a soluble chloride, and yields a white precipitate with barium chloride and a blue one with ammonia-water, soluble in excess of the latter. Commercial blue vitriol (*Cuprum sulfuricum crudum*, *P. G.*) is sometimes quite impure, but there is no difficulty in finding in our market very good and pure sulphate of copper.

Tests.—For detecting a small quantity of ferrous salt, this should be oxidized by chlorine; if now ammonia-water be added in excess, all the iron will precipitate as ferric hydrate, while the copper will form a deep-blue solution. The presence of zinc and earthy or alkaline sulphates is most conveniently detected by precipitating the solution completely with hydrosulphuric acid gas and evaporating the filtrate to dryness, when, in case a residue should have been left, its nature may be ascertained by the appropriate tests.

Pharmaceutical Preparations.—*CUPRUM ALUMINATUM*, *s. Lapis divinus*, is the name of an old preparation used in eye-waters which is still recognized in Europe. It is prepared by powdering 16 parts each of pure cupric sulphate, potassium nitrate, and alum, fusing the mixture in a porcelain capsule at a moderate heat, adding a previously-prepared mixture of finely-powdered camphor and alum each 1 part, stirring well, and immediately pouring upon a porcelain slab or plate to cool and harden, when it is broken into pieces and preserved in well-stopped bottles. The *pierre divine* or *pierre ophthalmique* of the French Codex contains a trifle less of camphor. In dispensing the *aluminated copper* it should be well triturated in a mortar with a few drops of water before the remaining ingredients are added, to facilitate the solution of the camphor. A collyrium, *Collyre de pierre divine* (*F. Cod.*), is made by dissolving 4 parts of aluminated copper in 1000 parts of water, and filtering.

Off. Prep.—*Cuprum ammoniatum*, *U. S.*

Allied Compounds.—*CUPRUM AMMONIATUM*, *Cuprum sulfuricum ammoniatum*.—Ammoniated copper, Ammonio-sulphate of copper, *E.*: Sulfate de cuivre ammoniacal, Cuivre ammoniacal, *Fr.*; Schwefelsaures Kupferoxyd-Ammoniak (Kupfer-Ammonium, Cuprammonium), *G.*—Formula of crystals $\text{Cu}(\text{NH}_4)_2\text{SO}_4 \cdot \text{H}_2\text{O}$; molecular weight 245.2.—Rub together in a glass mortar copper sulphate 4 parts and ammonium carbonate 3 parts until effervescence ceases; wrap the product in bibulous paper, dry it with a gentle heat, and keep it in a well-stopped bottle.—*U. S.* 1870. This preparation contains an excess of ammonium carbonate. It is obtained pure and in crystals by dissolving copper sulphate 1 part in ammonia-water 3 parts, filtering, and pouring upon the solution 6 parts of alcohol; in proportion as the latter abstracts the water from the solution prismatic crystals will be deposited. The salt will be at once separated as a crystalline powder on mixing the alcohol with the aqueous solution. Ammonio-sulphate of copper has a deep azure-blue color and an ammoniacal odor; exposed to the air, it loses ammonia and gradually changes to light-blue. It dissolves in $1\frac{1}{2}$ parts of cold water; the solution has an alkaline reaction and metallic taste, and on the addition of more water becomes turbid and produces a sediment. With a solution of arsenious acid a green precipitate (Scheele's green) is produced. When the salt is heated to 150°C . (302°F .) ammonia and water are given off, and an apple-green powder remains having the composition $\text{Cu}(\text{NH}_3)_2\text{SO}_4$, being a cupro-diammonium sulphate, while the medicinal salt is a cupro-tetrammonium sulphate; this contains 27.10 per cent. of ammonia and 32.38 oxide of copper. Berzelius obtained 26.40 and 34.0 per cent.

CUPRI OXIDUM, *Cuprum oxydatum*, *P. G.*—Oxide of copper, *E.*: Oxyde de cuivre, Safran de Vénus, *Fr.*; Kupferoxyd, *G.*— CuO ; mol. weight 79.2.—Dissolve copper sulphate 10 parts and sodium carbonate 15 parts each in hot water 50 parts; mix the solutions, and continue the heat until the voluminous precipitate becomes dense; collect this, wash it well, and expose it to a moderate red heat.—*P. G.* It is a soft, black, amorphous, heavy powder, which dissolves in dilute nitric acid without effervescence (absence of carbonate); this blue solution may be tested for iron and other metals by ammonia and hydrosulphuric acid in the same manner as copper sulphate. If to 1 Gm. of copper oxide be added 1 Ccm. of solution of ferrous sulphate, and afterward, without mixing, 1 Ccm. of strong sulphuric acid, a brown color should not be produced between the liquids (absence of nitrate). By precipitating a solution of copper sulphate with an excess of potassa or soda, and boiling, a brownish-black powder is obtained having the composition $3\text{CuO} \cdot \text{H}_2\text{O}$ (molecular weight 255.6); by red heat it is converted into anhydrous oxide, CuO .

Physiological Action.—Given to animals, sulphate of copper excites violent vomiting, and, if this is prevented by tying the œsophagus, insensibility, convulsions, and paralysis ensue. 60 grains of the salt thoroughly dissolved in water and injected under the skin of a dog destroy the animal in 24 hours, death following contraction of the pupils, paralysis of the hind legs, and a rapid pulse and respiration. The lungs, liver, and kidneys are gorged with dark blood, and the gastric mucous membrane is inflamed. This change in the blood, which becomes dark as well as thick and sticky, is considered

by Laborde to be a primary effect of the poison. These results, however, are not confirmed by more recent experimenters. Levi and Barduzzi gave a horse 15 grains of sulphate of copper daily for 30 days without injury, and, indeed, with manifest improvement of the animal's health, and when it was sacrificed no traces of a toxical operation could be found. Similar results were obtained by subjecting an ass to the same treatment. Galippe, following previous observers, found that dogs may be fed for a considerable period on food contaminated with copper without harm. The sulphate (and also the acetate, lactate, and citrate) of copper only caused vomiting, while small doses, gradually increased, were productive of no inconvenience.

Taken in small doses by man, sulphate of copper may be regarded as astringent and tonic. It does not act on healthy tissue as a caustic. In emetic doses its action is prompt and rapid, and it leaves no nausea or depression behind it. Even in very large (and in what may be called poisonous) doses it is rarely fatal to life, and recovery is usually rapid and complete, although in some cases derangement of the digestive function, with diarrhoea, may for a time continue. The symptoms of acute poisoning by this substance are headache, convulsions, colic, vomiting, collapse, suppression of urine, and sometimes jaundice. In the rare cases of death following directly upon poisoning by sulphate of copper congestion of the gastro-intestinal mucous membrane was the only discoverable lesion; in some instances of death occurring at a later period ulceration, and even sloughing and perforation, of the bowel have been found. In 1882, Dr. M. A. Starr reported the case of a woman who was fatally poisoned by an ounce of sulphate of copper (*Med. Record*, xxi. 564). She experienced burning pain and cramps in the abdomen, faintness, cramps in the legs, vomiting, and diarrhoea. On the third day she had headache, abdominal pain, micturition, and copious, inky urine containing albumen and hæmoglobin, but no red corpuscles; on the fourth day she grew yellow, and on the fifth fell into a comatose state, in which she died. The tissues were everywhere grayish-yellow and the blood was firmly clotted in the veins. There was no serious lesion of the stomach, but there was extensive ulceration of the lower end of the ileum, not confined to the glands. The liver was soft and somewhat fatty. The kidneys showed obstruction of the tubules with granular matter, and minute erosions of the membrane lining their pelvis. Three cases of criminal poisoning by sulphate of copper, all of which terminated fatally, are cited by Rey (*Thèse*, Paris, 1879).

Medical Uses.—The emetic operation of sulphate of copper is peculiarly appropriate to the treatment of pseudo-membranous *croup*, on account of its sustained mechanical and expulsive action, unaccompanied by nausea or other cause of depression. It has no specific operation whatever upon the seat of the plastic exudation, and therefore it can only be useful when the membrane has become spontaneously loose or been loosened by other agents—such, for instance, as mercury, inhaled lime-water or lactic acid, and possibly in some cases by depletion. In *malignant sore throat* a solution of 2 grains to the ounce has been given in tablespoonful doses every 10 or 15 minutes with alleged success. It is probable that the local application by means of a sponge of this or of a stronger solution would be, at the least, as efficient. There is some reason to think that *quartan agues* have been cured by sulphate of copper in doses of $\frac{1}{4}$ grain three times a day. It has been alleged that sulphate of copper is a more certain remedy than mercury for constitutional *syphilis*, but this claim of Martin and Oberlin does not appear to have been confirmed. Solutions of the salt form efficient injections for *gleet* and *leucorrhœa*. They should have a strength of 1 or 2 grains to the ounce. In *leucorrhœa* they may be applied on tampons. *Dysentery* and *diarrhœa* in their chronic forms, but especially the former disease, are often materially benefited by enemas of a pint of tepid water holding in solution from 10 to 20 grains of sulphate of copper. All forms of *ulcers* are very advantageously modified by it, as ulcers of the cornea, nostrils, mouth, vagina, and general surface, especially when they present an indolent aspect or arise in vitiated states of the system; for example, in ulcerative *stomatitis*, gangrene of the *pharynx*, *mercurial sore mouth*, etc. In *conjunctivitis*, especially of the chronic, and most of all of the granular form, this salt is of great service. When the granulations are large a crystal of sulphate of copper should be used. The same agent will sometimes suffice to arrest *hæmorrhage* from bleeding surfaces; for this purpose also it is sometimes used in the form of a powder, which may be mixed with an equal quantity of powdered gum-arabic. The stimulant and astringent action of the salt has been applied to the cure of various local affections of the skin, such as *acne rosacea*, *ichthyosis*, *alopecia*, etc. In 1866, Bamberger proposed sulphate of copper as an antidote to *acute poisoning by phosphorus*, upon the ground that the phosphorus reduces the metal, which coats the remaining phosphorus and renders it innocuous. He recom-

mended that sulphate of copper should be given first in an emetic dose, and then continued in smaller quantities. A critic of this method (1872) remarked that it was certainly very ingenious, but that there was no proof of its efficiency; and Eulenberg and Landois, who used carbonate of copper for the same purpose in experiments upon animals, found that the alleged antidote delayed their death, but did not prevent it.

Sulphate of copper is the basis of the most usual and convenient tests for *diabetic* sugar. They all essentially consist of oxide of copper, held in solution by an alkali through the medium of organic matter which, unlike sugar, has not the property of deoxidizing copper salts during ebullition (Pavy). The most usual form of the solution is as follows: Sulphate of copper 320 gr.; neutral tartrate of potash 640 gr.; caustic potash or soda 1280 gr.; distilled water 20 f3. Dissolve the sulphate of copper in 10 ounces of the water, and the tartrate of potash and the caustic potash or soda in the remainder. If on being boiled any deposit occurs a little excess of potash or soda must be added. When this solution is heated in a test-tube and a drop or two of diabetic urine is added, a more or less copious deposit of suboxide of copper forms as a yellow, orange-yellow, orange-red, or brownish-red precipitate. It is said that 1 grain of sulphate of copper dissolved in an ounce of glycerin forms a solution of which 1 drachm will reduce 1 grain of grape-sugar in a caustic alkali. 2 or 3 drops of the mixture are put into a test-tube and half an ounce of liquor potassæ added; the whole is then boiled, a few drops of urine added, and the whole boiled again" (Oppenheimer, *Med. Record*, xix. 27).

Ammoniated copper in medicinal doses does not produce any immediately sensible effects upon the healthy system, but in large doses it occasions nausea, giddiness, confusion or dimness of sight, vomiting, colic, constipation or diarrhoea, and, if persisted in, is said to cause muscular spasms or paralysis, wasting of the body, and death. It was once reputed to be an efficient remedy for *epilepsy*, but more accurate and continued observation has not sustained its character. It is one of the many medicines to which cures of *chorea* have been ascribed, and sometimes with such emphasis and detailed proofs that some faith in its efficacy cannot easily be withheld. If employed in this disease, it should be given at first in doses of $\frac{1}{2}$ grain (Gm. 0.03) three or four times a day in an aromatic vehicle, with a small proportion of laudanum, and rapidly but gradually increased until it begins to disturb the stomach. It should be administered when the stomach contains food. It is stated by Féréol to have cured trigeminal neuralgia that had resisted all the most accredited medicines. The medium dose employed by him was about 2 grains, and was given after meals for 10 or 15 days (*Monthly Abstract*, Aug. 1879, p. 349). Locally, it has been employed for the same purposes as sulphate of copper in solution and in ointments.

Administration.—As an emetic, sulphate of copper may be given in doses of from 2 to 10 grains (Gm. 0.10–0.60) of the powdered salt mixed with pulverized sugar, and repeated every 10 or 15 minutes if necessary. As a tonic or astringent, the dose is from $\frac{1}{4}$ grain to 2 or more grains (Gm. 0.016–0.12) in pill. For local application, solutions containing from 1 to 10 or more grains (Gm. 0.6–0.60) to the ounce of water may be used. Pencils of sulphate of copper are made by fusing together 2 parts of this salt with 1 of alum. They are also produced by first depriving the sulphate of its water of crystallization, reducing it to a fine powder, and then, after placing it in paper moulds, surrounding them with wet cloths, which restores the water of crystallization.

CUPRUM, Br.—COPPER.

Cuprum filum.—Copper wire, E.; *Cuivre, Fil de cuivre*, Fr.; *Kupfer, Kupferdraht*, G. Symbol Cu. Atomicity bivalent. Atomic weight 63.2.

Fine copper wire, about No. 25.

Origin.—Copper, which has been known from the earliest times, is often found in the metallic state as native copper, notably near Lake Superior; occasionally it is met with in the oxidized state as black and red copper ore or as a carbonate in malachite, and frequently as sulphuret in copper pyrites, copper glance, and gray copper ore, etc. It is a natural constituent in minute quantities of some mineral springs and of many vegetable and animal organisms. The smelting process is rather complicated for many ores, and depends mainly upon the oxidation of the sulphurets by roasting and the reduction of the metal by means of charcoal or by fusing a mixture of oxide and sulphide of copper. Arsenic and antimony, which are often present, are expelled by the repeated roastings, together with the sulphur, and the iron is made to enter the slag.

Properties.—Copper is a very sonorous, malleable, and ductile metal of a reddish color, having the specific gravity 8.92 or when hammered 8.95. It melts at a bright-red

heat, first becoming brittle, and expands in volume on congealing. It is inferior to iron in tenacity or strength and in hardness, but superior to it as a conductor of electricity and heat and in resisting the chemical action of moist air. Copper is not acted upon by cold concentrated or hot dilute sulphuric acid, but it dissolves readily in nitric acid. The most important of the numerous alloys of copper are *brass*, containing about 28 to 36 per cent. of zinc; *bronze*, containing 8 to 12 per cent of tin, and sometimes a little zinc and lead; *bell-metal*, containing 20 to 25 per cent. of tin; and *German silver*, composed of 8 copper, $3\frac{1}{2}$ zinc, and 3 or 4 nickel.

Chemical Characteristics.—Copper forms two series of salts—*cuprous* and *cupric*, the former of which are of little importance. The anhydrous cupric salts are usually white, the hydrated green or blue; the soluble ones have an acid reaction, and their solutions are decomposed by iron, zinc, and the earth metals, with the precipitation of copper. Potassa precipitates a greenish-blue basic salt or blue hydrate, which when heated turns to black $(\text{CuO})_3\text{H}_2\text{O}$ or CuO . Potassium carbonate precipitates green oxycarbonate of copper, the precipitate turning black on boiling. Ammonia-water and ammonium carbonate occasion bluish-green precipitates which dissolve in an excess, forming deep azure-blue solutions. Ferrocyanide of potassium yields a brown-red precipitate, which is insoluble in dilute acids. Sulphuretted hydrogen separates from acid solutions brown-black sulphide of copper. Potassium iodide produces a grayish-white precipitate of cuprous iodide, one-half of the iodine being at the same time liberated.

Pharmaceutical Uses.—Copper wire is employed in the preparation of *Spiritus ætheris nitrosi* for generating nitrous acid.

Copper Pigments.—**BREMEN BLUE** or **BREMEN GREEN** is cupric hydrate, prepared by precipitating a copper salt with an alkali and drying the precipitate below 40°C . (104°F). Used as a water-color, it remains blue, but if used as an oil-color it becomes green from the formation of a copper soap. Basic cupric carbonate is sometimes sold under the same name.

BRUNSWICK GREEN is either oxycarbonate or oxychloride of copper.

MOUNTAIN GREEN or **MINERAL GREEN** is powdered green malachite or artificially-prepared oxycarbonate of copper.

SCHÉELE'S GREEN. Copper sulphate is precipitated by a solution of arsenious acid in sodium carbonate; its composition, according to Sharples (1877), is $\text{Cu}_3\text{As}_2\text{O}_6 \cdot 2\text{H}_2\text{O}$.

SCHWEINFURT GREEN or **PARIS GREEN** is aceto-arsenite of copper, prepared by boiling the mixed hot solutions of cupric acetate and arsenious acid.

Most of these pigments are also sold under other names than those given above. As met with in commerce, they are frequently mixed with alumina or calcium and barium compounds, and thus constitute lower grades. Mixtures of chrome-yellow and Prussian blue are likewise sold under several of the above names.

Physiological Action.—Copper in the metallic state is not known to exercise any specific action upon the economy. Workers in the metal, although constantly covered with its dust and receiving such large quantities of it into the system through the lungs and digestive apparatus that it is readily detected in the urine, do not appear to be liable to any special diseases, although they have a more or less anæmic appearance and are subject to giddiness, lassitude, and dyspepsia. They are apt to lose their teeth early, and their gums present a green or olive-colored line, and the teeth are discolored in the same manner. In 1869, Dr. Clapton pointed out the absolute freedom of the workmen in copper from cholera or choleraic diarrhœa (*Trans. Clin. Soc.*, iii. 7). And in 1880, Dr. Burq (*Bull. de thérap.*, xeviii. 330) not only maintained this opinion, but also alleged that these workmen are equally insusceptible of contracting typhoid fever, and that musicians who play on brass instruments are not liable to either disease. On the other hand, there can be no doubt that persons who work at trades in which copper-leaf is employed in the form of "bronze powder" may suffer from its poisonous effects. The symptoms do not seem to be uniformly alike, for diarrhœa or constipation may exist; but in all cases there is abdominal pain and tenderness, nausea and vomiting, an anæmic appearance of the skin, and a purplish discoloration of the gums. Copper has been found in the feces. In one case death was ascribed to peritonitis. The treatment of such poisoning should be by gentle but repeated purgation with salines, warm baths, and a milk diet (*British Med. Jour.*, July 24, 1880; *Phila. Med. Times*, xi. 457).

CURARE.

Urari, Wourari, Wourali, Woorara.

Preparation.—The latest information concerning the preparation of this South American arrow-poison is from Dr. Jobert (1878), who, writing from Belen de Para to

the French Academy, made the following statements: The principal ingredients are *urari u ra* (probably *Strychnos Castelnanæna*, Weddell) and *eko*, also called *pai du maharâo* (probably *Cocculus toxiferus*, Weddell). The young bark of these plants is well scraped, and the scrapings are mixed in the proportion of 4 parts of the former and 1 part of the latter; the mixture is well kneaded with the hands, and, in a funnel made of palm leaf, exhausted with cold water, the liquid being returned seven or eight times. The red infusion is boiled with fragments of *taja* (an Aroidea) and *mucra-ca-ha* or *cone* (probably *Didelphys cancrivora*). After about 6 hours the liquid has acquired a thick consistence, and is mixed with the scrapings of three species of pepper (*Artanthe?*) and *tauma-gere*, and again boiled and allowed to cool, when it will have the consistence of a thick paste.

Dr. Richard Schomburgk (1879) observed the following ingredients to be used in the preparation of *urari* or *urati* in British Guiana: Bark of *Strychnos toxifera*, Schomburgk, 2 pounds; Str. Schomburgkii, Klotzsch. Str. cogens, Bentham (*arimaru*), and *wakarimo*, of each $\frac{1}{4}$ pound; roots of *tarvieng* and *tararemu*, of each $\frac{1}{2}$ ounce; four small pieces of wood of a species of *Xanthoxylea* called *manuca*. An extract is made by boiling these articles with water, straining, and adding to the thick liquid the slimy juice pressed out of the fleshy root of a species of *Cissus*, called *muramu*; the mixture is further evaporated by exposing it to the sun.

Planchon (1879) added to the above-named species *Strychnos Gubleri*, Planchon, which is used on the Rio Negro; Str. Crevauxii, Planchon, in Upper French Guiana; and Str. Yapurensis, Planchon, on the Yapura River. In addition to these, Rouhamon (*Strychnos*, Martins) guianensis, Aublet, Str. cogens, Bentham, Paullinia Cururu, Linné, and other plants have been named as being used in the preparation of this poison in different parts of South America.

Properties.—Curare is a blackish-brown extract, brittle or hygroscopic, and of a very bitter taste; cold water dissolves about 75 per cent.; this portion contains the poisonous alkaloids, and is insoluble in ether and very sparingly soluble in absolute alcohol.

Constituents.—Boussingault and Roulin (1828) separated from curare some fat, brown resin, red coloring matter, gum, clay, and the alkaloid *curarine*, which was previously discovered by A. Buchner (1827). In its pure state the alkaloid forms colorless prisms which have a very bitter taste, but less persistent than strychnine. It has a slight alkaline reaction, is deliquescent in moist air, freely soluble in alcohol, sparingly so in chloroform and amyl alcohol, and insoluble in absolute ether, carbon bisulphide, and benzol. It is colored deep-red by nitric acid, and by concentrated sulphuric acid acquires a carmine-red color, which on the addition of bichromate of potassium, becomes violet, the reaction being very similar to that produced by strychnine under the same treatment, but the coloration is more permanent. Sachs (1878) gives it the formula $\text{NC}_{18}\text{H}_{35}$, and states that it exists in curare as sulphate, and that Preyer's alkaloid, which was colored blue by sulphuric acid, consisted mainly of calcium phosphate and coloring matter. The alkaloid yields white, yellow, or brownish precipitates with all the group-reagents for alkaloids, and is precipitated yellow by potassium ferricyanide, and white by potassium ferrocyanide, sulphocyanide, and iodate and by sodium phosphate and arsenate.

Physiological Action.—*On Animals:* The observations made more than half a century ago by Fontana, Brodie, Emmert, and others agree essentially with the results of recent experiments as to the action of this substance. They found that it acted much more energetically upon birds than upon quadrupeds—a peculiarity which is now known to depend upon its very slow elimination with the urine in the former, and its rapid discharge with the same excretion in the latter class of animals. So complete is this elimination that the urine of an animal poisoned by curare is itself actively poisonous. The most conspicuous phenomena observed when a solution of the poison is injected into the blood or hypodermically are the following: According to Couty, the primary effect of very small doses is stimulant, the animal becoming agitated and excited, the pupils alternately contracting and dilating, while the nervous excitability is augmented. A general muscular paralysis, voluntary and reflex, ensues, including that of the muscles of respiration, which first affects the hinder limbs of quadrupeds, but ultimately involves all of the voluntary muscles, so that if the dose be duly proportioned the animal may remain for hours alive, but entirely motionless. The movements of the muscles of organic life are less promptly and deeply affected than the voluntary muscles. Occasionally, when death is rapid, convulsions occur, which are occasioned by asphyxia due to respiratory paralysis, but the heart continues to beat after other signs of life become extinct, and sometimes even then the poisoned animal may be revived by artificial respiration.

On Man: The original experiments upon animals agree with those subsequently made upon man, in showing that curare is rarely poisonous when taken into the stomach. Locally, however, it acts as an irritant to the denuded cutis, causing severe pain and subsequently inflammation; when used hypodermically, it is apt to produce obstinate and painful ulcers: its powder irritates the mucous membranes, exciting lachrymation and a copious nasal and salivary flux. Internally, it is a diaphoretic, and in some cases it is said to have rendered the urine saccharine. It does not seem to influence the pulse or the temperature. In large doses, given hypodermically or by the stomach, it sometimes causes chilliness, followed by fever and sweating, but more usually its effects are exhibited by the voluntary muscular system, which is in every part relaxed. This action upon the muscles of the face produces an apathetic, dull expression, especially when the upper eyelids fall, covering the eyeball; and, as the patient is unable to open his eyes, he is apt to believe himself stricken with blindness. In other cases the muscles of the eyeball are affected, and mydriasis, diplopia, strabismus, and ptosis occur. The lower limbs are first and chiefly affected with loss of muscular power, so that the gait is staggering. These phenomena are variously explained by different observers and experimenters according to their several theories of the nervous functions. The greater number agree that the primary operation of curare is upon the terminations of the nerves, and not upon their central origins; but Dr. Poole (*Med. Record*, xix. 597) infers from the reported facts that the ordinary effect of curare is to paralyze the motor nervous trunks.

Medical Uses.—Curare has been employed chiefly in the treatment of several grave diseases attended with nervous spasm, and especially tetanus, epilepsy, chorea, and hydrophobia. It is well known that tetanus, even of the traumatic form, has been treated successfully with various medicines which control muscular action, and this one is reported to have cured thirteen out of thirty-three cases (Demme; Busch). Other persons have published similar results, but in isolated cases. There can be no doubt that, appropriately administered, it effectually controls the spasms, probably by its direct action upon the muscles, and thereby spares the patient the exhaustion which the spasms produce. Practically, however, curare is seldom employed in the treatment of tetanus. Vulpius even comes to the conclusion that it does not favorably influence the termination of that disease (*Leçons sur les Substances toxiques*, p. 396). In epilepsy Kunze claims to have cured nine out of thirty-five cases by this medicine, but in a later report only six cases out of eighty (*Med. Times and Gaz.*, Nov. 1878, p. 523); and Eddlefsen three out of thirteen cases, using hypodermic injections with a primary dose of $\frac{1}{3}$ grain (*Edinb. Med. Jour.*, xxvii. 842). In chorea it appears to be useless. It has also been tried in rabies, uniformly with the result of appeasing or suspending the spasms, and in at least three cases it is said to have cured the disease. A critical examination of these cases leaves an impression of doubt as to their nature. The reporters do not always seem to have been aware of the distinction between rabies canina and hydrophobia, nor of the alleged cure of the disease by various remedies, such as *Xanthium spinosum*, the hot vapor-bath, oxygen, etc. It should also be noted that in several cases the medicine appears to have been thoroughly employed without the least advantage. At the same time, its possible inertness in these instances should not be lost sight of, and in no case should any of it be used that has not first been tested upon an animal. Curare is best administered hypodermically in a filtered watery solution of the strength of 1 per cent., each injection containing about $\frac{1}{10}$ grain (Gm. 0.006). But in a remarkable case of cure (Offenburg, 1877) about $\frac{1}{4}$ grain (Gm. 0.02) was administered as often as the spasms threatened to return. Within 4 hours seven injections, amounting to Gm. 0.19, or 2 $\frac{1}{4}$ gr., were given hypodermically in a 5 per cent. solution (*Arch. f. Exp. Pathol.*, xi. 308). In all cases it must be repeated so as to maintain complete muscular relaxation. It has also been used endermically and by the rectum. Curarin has been employed as a sulphate in from one-twentieth to one-tenth of the dose of curare, but Sachs has shown that this pretended curarin is really phosphate of lime.

CURCAS.—PURGING-NUT.

Semen ricini majoris.—Physic-nut, Barbadoes-nut, E.; Pignon d'Inde (des Barbades), *Semence du médicinier*, Fr.; Purgirnuss, Schwarze Brechnuss, G.

The seed of *Curcas purgans*, *Ansonia*, s. *Jatropha Curcas*, Linné.

Nat. Ord.—Euphorbiaceæ.

Origin.—A medium-sized monœcious shrub indigenous to the West Indies and South America, but naturalized in other tropical countries. It has smooth, angularly three- or

five-lobed, cordate leaves, paniculate cymes of greenish-yellow bell-shaped flowers, the pistillate ones few and largest, and tricocous, obtusely triangular, and blackish capsules, each cell containing one seed.

Description.—The seeds are about $\frac{1}{2}$ inch (2 Cm.) long, ovate-oblong, flattened from the back, with a broad whitish hilum and caruncle at one end, black, not glossy, somewhat rough, and marked with numerous small cracks. The kernel has the shape of the seed, and consists of an oily albumen which encloses the embryo. The seeds are inodorous; the kernels have a sweetish and oily taste, which gradually becomes acrid and burning.

Constituents.—The principal constituent is the fixed oil, of which Arnaudon and Ubal dini (1858) obtained 37.5 per cent. It is light yellow or colorless, of spec. grav. 0.92, congealing to a butyraceous mass at -8° C. (17.6° F.), inodorous, and nearly insoluble in alcohol. When distilled with potassa, caprylic alcohol is obtained. Bouis (1854) separated a liquid and solid fatty acid, and named the latter *isocetic acid*, $C_{15}H_{30}O_2$. Cadet de Gassicourt (1824) found in the seeds also an acrid resin.

Allied Seeds.—*ANDA GOMESII*, *Jussieu*, s. *Anda brasiliensis*, *Raddi*, s. *Joannesia principis*, *Vellozo*. A large tree of Brazil, known there as *anda-assu*, bearing a heart-shaped, obtusely quadrangular drupe, the seeds with a white fleshy arillus. The seeds resemble chestnuts, are somewhat reniform, dark-brown, and of an almond-like taste; they yield about 50 per cent. of a reddish inodorous crude drying oil, which is an active purgative in doses of 10 Gm., and is more limpid than, and free from the mawkish odor and unpleasant taste of, castor oil. One or two seeds act as a violent cathartic, often also as an emetic.

CURCAS MULTIFIDUS, *Endlicher*, s. *Jatropha multifida*, *Linne*, is a South American shrub, the seeds of which resemble the purging-nut, but are smoother and brown. According to Soubeiran, the oil of these seeds is very similar to, if not identical with, that of the latter.

EUPHORBIA LATHYRIS, *Linne*, s. *Tithymalus lathyris*, *Scopoli*.—Caper spurge, Garden spurge, *E.*: *Euphorbia*, *Catapuce*, *Fr.*: Wolfsmilch, Springkraut, *G.*—A South European herb, cultivated in gardens and somewhat naturalized in North America, the seeds of which were formerly official as *semen cataputiae minoris*. They are about $\frac{1}{2}$ inch (3 Mm.) long, oval, obtuse, on one end with the hilum and caruncle, brown, marbled with gray, and rugose. The oil separates a crystalline mass on standing.

Physiological Action.—It is said that the expressed oil of curcas-seeds acts chiefly as a purgative, and that in the dose of about 12 drops it produces effects like those of an ounce of castor oil. It is more like croton oil in its operation. The acrid emetic principle resides chiefly in the embryo. It is stated that if the embryo is wholly removed four or five of the seeds may be used as a purgative without producing either vomiting or griping. This opinion is supported by experiments upon dogs. A number of cases have occurred of poisoning by eating the seeds entire. In one case a man who had eaten five of them soon complained of burning in the mouth and throat, and the whole abdomen felt distended and sore. In a few minutes vomiting occurred, and was repeated five times in the course of an hour, accompanied with active purging. The pain continued; the patient complained of feeling hot and giddy; he then became delirious, and afterward insensible. On regaining consciousness several hours later his face was pale, his hands cool, the pulse 110 and weak. He recovered. In 1854, at Birmingham, Eng., more than thirty boys were poisoned by eating these seeds. In some of them, besides the symptoms just mentioned, there was a hot skin and an appearance of drowsiness, which may, however, have been due to exhaustion produced by the evacuations. They all made good recoveries. The oil applied to the skin irritates it.

Medical Uses.—In the East Indies the juice of the plant and the oil are said to be used locally in the treatment of *cutaneous eruptions*, *rheumatism*, and *hemorrhoids*, and, in liniments to stimulate the secretion of *milk*. The oil has been employed internally in *constipation*, *dropsy*, *worms*, etc., and externally in the diseases mentioned, and also in *paralyses*, pain in the *ears*, *deafness*, etc. In a word, it has, in a less degree, the qualities and medical virtues of croton oil, and appears to be purgative in about the same dose.

The uses of the oil of *Anda Gomesii* are stated under *OLEUM RICINI*. The oil obtained by expression from *Euphorbia lathyris*, and the seeds themselves, were formerly used in the south of France and in Italy as purgatives. Five seeds caused vomiting and diarrhoea in one experiment, but ten were required to produce a like effect in another. The expressed oil acted purgatively, and the seeds which furnished it were no longer purgative in the same degree as at first (*Husemann, Toxicologie*, p. 447).

CURCUMA.—TURMERIC.

Rhizoma curcuma.—*Curcuma*, *Souchet des Indes*, Fr.; *Kurkuma*, *Gellbaurz*, G.

The rhizoma of *Curcuma longa*, *Linné*, s. *Amomum Curcuma*, *Jacquin*, s. *Curcuma rotunda*, *Linné*. *Woodville*, *Med. Bot.* 252; *Bentley and Trimen*, *Med. Plants*, 269.

Nat. Ord.—Zingiberaceæ.

Origin.—The plant yielding turmeric is a perennial indigenous to India, and is extensively cultivated throughout Southern Asia and in many islands of the Indian Ocean. It produces a tuft of radical leaves, which are about 3 feet (90 Cm.) long and have a prominent midrib; the scape bears a few sheathing bracts below, and terminates with a spike of 6 inches (15 Cm.) bearing orange-colored flowers in pairs from the axils of spreading bracts. The United States import annually about 1,000,000 pounds of turmeric.

Description.—The central portion of the rhizome of the different species of curcuma is tuberous, and sends out nearly cylindrical branches, some of which become

fusiformly thickened toward their ends, and then contain a very pure starch. Aside from these spindle-shaped, amylaceous tubers, the subterraneous stem is of two forms, and the commercial turmeric must vary as one or the other or both forms are collected, which were formerly supposed to have been produced by two distinct species.

FIG. 91.

Round Turmeric.

FIG. 92.

Long Turmeric.

FIG. 93.

Curcuma: transverse section, magnified 3 diam.

Curcuma rotunda, or round turmeric, attains a length of $1\frac{1}{2}$ to 2 inches (38 to 50 Mm.) with a diameter of 1 inch (25 Mm.) or more; it varies in shape between globular, oblong, and pyriform, has annular marks from the scars of the leaf-sheaths, and is beset with root-scars and a few fibres or their remnants. *Curcuma longa*, or long turmeric, is 1 to 2 inches (25 to 50 Mm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6 to 12 Mm.) thick, straight or curved, mostly simple, nearly cylindrical, and somewhat annulated by the leaf-scars. The two varieties are externally covered with a yellowish-gray, soft, and friable corky layer, and break with a short and smooth fracture of a horny or resinous lustre. The interior is of a gamboge- to brown-yellow color, the centre usually of a deeper tint, and separated from the outer portion by a circular line, indicating the nucleus-sheath. The fibro-vascular bundles are scattered throughout the entire rhizome, and are more numerous near the nucleus-sheath; the polyhedric parenchyma-cells of the cortical and inner layer contain starch, resin, and drops of volatile oil. The nearly uniform color and glossy appearance of the interior are due to the scalding of the rhizomes previous to drying, whereby the starch has been converted into a pasty mass. The quality of turmeric is approximately judged by the brightness of the tint and the degree of lustre upon the fracture. Turmeric has a peculiar aromatic odor and a warm, aromatic, and bitterish taste.

The principal commercial varieties are—*Chinese turmeric*, which consists of many central rhizomes with well-developed branches; *Bengal turmeric*, mostly in slender branches of a deep reddish tint; *Madras turmeric*, in thick lateral branches, mixed with transversely-cut tubers of a gamboge tint; *Java turmeric*, which consists of rather small tubers and branches that are often transversely and longitudinally cut; and *Cochin turmeric*, in sections or slices of a larger tuber, some being marked with rather large depressed stem-scars; they are probably derived from another unknown species.

Constituents.—The investigations of Bolley, Suida, Lange (1868), Gajewsky (1870, 1872), Kachler (1870), and Flückiger (1876) have been supplemented and partly modified by C. L. Jackson and A. E. Menke (*Am. Chem. Jour.*, 1882-83, iv.). By distillation with water about 1 per cent. of volatile oil is obtained. Treatment with cold ligroin

yields 11 per cent. of viscid oil, a small portion of which distils, under diminished pressure of 60 Mm., under 193° C., and a second portion, *turnerol*, $C_{19}H_{36}O$, between 193° and 198° C. (379° and 388° F.), leaving a viscous body. *Turnerol* is pale-yellow, agreeably aromatic, dextrogyre, of the density .9016 at 17° C., and boils under ordinary pressure at 285° – 290° C. (545° – 554° F.), with partial decomposition. The *curcuminol* of other chemists was stated to have the formula $C_{10}H_{14}O$ and the boiling-point 245° C. (473° F.).

The coloring matter, *curcumin*, is best obtained pure after removing the oil by exhausting the powder with ether and recrystallizing from alcohol; the yield, involving much loss, was only 0.3 per cent. The yellow crystals, $C_{14}H_{14}O_4$, have a vanilla-like odor, fuse at 165° C. (329° F.), are readily soluble in alcohol, chloroform, and ether, very little in cold benzol and benzin, and freely and with a red-brown color in alkalies. Oxidation by potassium permanganate or other weak oxidizing agents yields vanillin (melting-point 79° C.); by chromic acid the products are carbonic and acetic acids; and with nitric acid oxalic acid is obtained. The carmine-colored potassium compound is insoluble in strong alcohol and ether; the zinc compound is soluble in water; the insoluble lead and silver compounds are easily altered. By boiling an alcoholic solution of curcumin with boric acid and decomposing the compound with hot water, Schomberger (1866) obtained yellow *pseudo-curcumin*, which is not reddened by boric acid, and is soluble in alkalies with a greenish-gray color. Boiling as before, but in the presence of sulphuric acid, *rosocyanin* is formed, which is crystalline, insoluble in water, benzol, and ether, and soluble with a beautiful red color in alcohol. Alkalies color it blue; the solution on boiling turns blood-red, then yellow, and now contains pseudo-curcumin.

The other constituents of turmeric are starch, gum, resin, and others of no medicinal importance. Kachler (1870) separated from the infusion a notable quantity of *acid potassium oxalate*. Tincture of turmeric shows a blue fluorescence, due to curcumin.

Pharmaceutical Uses.—Turmeric is employed for the detection of alkalies and of borates. Paper saturated with the tincture is colored brown-red by alkalies, the yellow color being restored by acids. Soluble borates likewise produce a brown-red color, which is not altered on the addition of dilute acids. It is occasionally employed for coloring pomades and ointments, as in the *Unguentum flavum s. Ung. althææ* (P. G. 1872), which is made by digesting for half an hour 1 part of turmeric with 50 parts of lard, fusing together with yellow wax and Burgundy pitch, each 3 parts, and straining.

Medical Uses.—Turmeric has no medicinal properties that require notice. Its sole use is to prepare a test-paper. In India and China it is employed as a condiment.

CYCLAMEN.—CYCLAMEN.

Sow-bread, E.; *Arthanite*, *Pain de pourcean*, Fr.; *Erdscheibe*, *Erdprot*, *Schweinbröt*, G.

The tuber of *Cyclamen europæum*, Linné.

Nat. Ord.—Primulacææ.

Origin.—The species grows in shady places and rocky woodlands of Southern Europe, and is met with in cultivation. It has a few roundish, heart-shaped leaves of a dark-green color, marked with white above and purplish beneath, and several stalks, each bearing a nodding, fragrant, pink-colored flower, and coiling up after flowering so as to bring the capsule to the ground.

Description.—The tuber is 1 to 2 inches thick, flattish-circular or depressed globose, dark-brown externally, internally white, mealy, with a rather thin bark and with narrow and short fibro-vascular bundles loosely arranged in irregular circles. In the fresh state it has a burning, acrid taste; after drying this is milder.

The similar tubers of *Cyclamen hederæfolium*, Aiton, and *C. persicum*, Miller (s. *C. latifolium*, Sibthorp), which are indigenous to Southern Europe and the Levant, have similar properties; these plants are also cultivated for ornament.

The pyriform or spindle-shaped tubers of *Lathyrus tuberosus*, Linné, which are of the size of a walnut, are said to be occasionally substituted for those of cyclamen; they have a mucilaginous taste.

Constituents.—Aside from starch, gum, pectin, and other common principles, Saladin (1830) isolated *cyclamin* or *arthanitin*, $C_{20}H_{24}O_{10}$. It is white, amorphous or in minute crystals, of a bitter and acrid taste, soluble in bisulphide of carbon, chloroform, alcohol, and in water, and insoluble in ether and fixed and volatile oils. Its aqueous solution foams like soap-water, is precipitated by tannin, and when boiled with dilute acids yields glucose and resinous *cyclamiretin*.

Physiological Action and Medical Uses.—Experiments made by Claude Bernard led him to the conclusion that cyclamin resembles curare in its action, but as he injected a large amount of liquid in which the cyclamin was dissolved into the trachea of animals, it is evident that they may have died of asphyxia, and not of cyclamin. While pigs can eat any quantity of cyclamen-root without harm, fish are poisoned by its juice as well as by cyclamin. The former is said to be used in Sicily and Italy for catching fish. They are not affected tetanically, as by cocculus, but die asphyxiated through imperfect respiration. Small fish die in water containing the $\frac{1}{1000}$ part of the juice of cyclamen-root. According to Schroff—1, cyclamin does not act upon the sound skin; 2, in the mouth it produces a very unpleasant sensation and taste, and excites salivation; 3, in the stomach it causes burning, oppression, nausea, and vomiting, and in this organ, as in the intestine, it occasions inflammation; 4, in the connective tissue it excites inflammation, which may be followed by gangrene; 5, it does not affect the brain, spinal marrow, or nerves; 6, it salivates men when not taken by the mouth, but by the veins; 7, its action is analogous to that of smilacin, senegin, and saponin. It has been stated by Vulpian that when cyclamin is given to frogs the animals sicken, and after a few days die. Their blood is found to contain a multitude of vibrios, some of which are seen even in the interior of the red corpuscles.

Cyclamen-root loses much of its acrimony by keeping, and has been recommended under such circumstances as a purgative in the dose of 10 grains (Gm. 0.60) triturated with powdered gum. On the other hand, the fresh root has sometimes occasioned alarming effects. Bulliard states that "in the north of France, where it is much used as a purgative, it often produces violent vomiting, followed by cold sweats, vertigo, ringing in the ears, and gyratory or convulsive movements; often blood is ejected by vomiting or purging, and sometimes there is even fatal hypercatharsis." Formerly it entered, with other drastic purgatives, into a liniment which caused purgation when applied to the abdomen in cases of *worms* and of *dropsy*. Externally, the fresh tuber has been proposed as a stimulating cataplasm for *carbuncles*, *abscesses*, enlarged *glands*, etc. Dose, 5 grains (Gm. 0.30). A decoction is prepared with from 1 to 3 drachms (Gm. 4–12) in a pint (Gm. 500) of water.

CYDONIUM, U. S.—CYDONIUM.

Semen cydonia.—Quince-seed, E.; Semences (Pépins) de coing, Fr.; Quittensamen, Quittenkerne, G.

The seed of *Cydonia vulgaris*, Persoon, s. *Cyd. europæa*, Savi, s. *Pyrus Cydonia*, Linné, s. *Sorbus Cydonia*, Crantz. Woodville, *Med. Bot.*, 182; Bentley and Trimen, *Med. Plants*, 106.

Nat. Ord.—Rosacæ, Pomeæ.

Origin.—The quince tree, which attains a height of 20 feet (6 M.) or remains shrubby, is probably indigenous to Asia Minor and Persia, but was anciently cultivated, and is now naturalized, in the Mediterranean basin and cultivated in the temperate parts of Asia, Africa, Europe, and America. It has shortly petiolate, entire, ovate or obovate leaves, which are woolly beneath; ovate, glandular, and denticulate stipules; handsome, pale rose-colored flowers; and a pyriform or subglobular golden-yellow fragrant fruit, with five cells, each containing about twelve closely-packed seeds.

Description.—The seeds are $\frac{1}{4}$ or $\frac{3}{8}$ inch (6 to 10 Mm.) long, of an oblong or oval shape, but flattened and three-sided by mutual pressure; the somewhat pointed hilum at the narrow end is connected by the ridge-like raphe along the sharper edge with the chalaza at the other slightly-beaked end. The testa is of a brown color, covered with a mucilaginous epithelium, by which the seeds of one cell are united into a mass. The embryo is of the size and shape of the seed, consists of two plano-convex oily cotyledons, with a thick straight radicle pointing toward the hilum, and possesses the taste of bitter almonds. The unbroken seeds are mucilaginous. The mucilage is contained in the epithelial cells, which form the grayish or whitish covering of the seed,

FIG. 94.

Quince-seed and section.

FIG. 95.

Quince-seed: section through epithelium, testa, tegmen, and portion of cotyledon; magnif. 150 diam.

contained in the epithelial cells, which form the grayish or whitish covering of the seed,

and when immersed in water swell up considerably, forming a thick jelly-like mass with 40 parts of water to 1 of seeds.

Constituents.—Quince-seeds yield about 20 per cent. of dry mucilage, which has the composition $C_{12}H_{20}O_{10}$ and contains some calcium salts and albumen. Treated with nitric acid, it yields oxalic acid. The mucilage has little adhesive power, is not affected by solution of borax, and is precipitated by alcohol and by metallic salts.

Off. Prep.—Mucilago cydonii, *U. S.*

Allied Plant.—CYDONIA (PYRUS, *Thunberg*) JAPONICA, *Persoon*. This frequently-cultivated ornamental shrub is smooth throughout, has oval serrate leaves and bright-red flowers, and bears globular fruits of an aromatic acidulous taste.

Medical Uses.—The pulp, and especially the rind, of the fruit have a certain astringency which has caused them to be used in cases of *mucous profluvia* and passive *hæmorrhages*, but particularly in *leucorrhœa* and *uterine hæmorrhage*, and also in *diarrhœa*. They are rather domestic than official medicines.

CYNANCHUM.—SWALLOW-WORT.

Domphe-renin, Hirundinaria, Fr. ; Schwalbenwurz, Giftwende, G.

The root of *Cynanchum* (*Asclepias, Linné*) Vincetoxicum, *Persoon*, s. Vincetoxicum officinale, *Moench*.

Nat. Ord.—Asclepiadaceæ.

Origin.—This plant grows in rocky places throughout the greater part of Europe. It is about 2 feet (60 Cm.) high, and has nearly sessile cordate-ovate and acuminate leaves, the axils of which bear the small umbels of about nine flowers, having a white corolla and yellowish crown.

Description.—The subterraneous portion consists of a very knotty, many-headed horizontal root-stock, with cup-shaped stem-sears, and with numerous nearly simple rootlets, which are about 6 inches (15 Cm.) long, longitudinally wrinkled, pale-brownish externally, and showing upon the transverse fracture a rather thick brownish bark with white dots and a finely porous yellowish medullium. The peculiar odor of the fresh root, which resembles that of valerian, disappears nearly altogether on drying; the taste is sweet, bitterish, and acrid.

Constituents.—Feneulle (1825) submitted the root to analysis, but did not succeed in isolating the emetic principle. He determined the presence of pectin, fat, volatile oil, etc.

Medical Action and Uses.—This plant and the bitter principle derived from it are extremely irritating, and, taken internally, occasion nausea, vomiting, and purging, depending upon an active irritation of the gastro-intestinal mucous membrane, as experiments on animals show. Its action has been compared to that of scammony, for which it has been proposed as a substitute in France. Occasionally it has been used in *dropsy* and *diseases of the skin*. Its fresh juice is purgative in the dose of about 15 grains (Gm. 1).

CYPRIPEDIUM, *U. S.*—CYPRIPEDIUM.

Rhizoma cypripedii.—*Ladies'-slipper root, E. ; Racine de cyripède jaune, Valériane américaine, Fr. ; Gelbfrauschuh-Wurzel, G.*

The rhizome and rootlets of *Cypripedium pubescens, Willdenow*, and of *Cypripedium parviflorum, Salisbury*.

Nat. Ord.—Orchidaceæ.

Origin.—These herbaceous plants are indigenous to Canada, and to the United States as far south as North Carolina; they grow in low woodlands and boggy localities and flower in May and June. The two plants are distinguished from each other by their size, *Cypr. pubescens* being the taller, growing about 2 feet (60 Cm.) high, and by their flowers, which in the species named have lanceolate sepals and a laterally-flattened lip which is arched above, while the flowers of *Cypr. parviflorum* are smaller, with lance-ovate sepals and the lip flattened from above. In both species the lip of the yellow flowers forms an inflated obtuse sac which is likened to a slipper.

Description.—The rhizomes are horizontal, bent up and down, nearly cylindrical, about $\frac{1}{2}$ inch (3 Mm.) in diameter, nearly 4 inches (10 Cm.) long, above beset with broad circular cup-shaped scars of the overground stems, the more recent ones with fibrous tufts of ligneous tissue; the numerous simple rootlets are mainly attached on the lower half

of the rhizome, attain a length of 6 to 8, occasionally even 18 or 20 inches (15 to 20, even 45 or 50, Cm.). The rhizomes and rootlets of *Cypr. parviflorum* are rather slender and shorter, and after drying of an orange-brown color, while the coarser parts of *Cypr.*

FIG. 96.

Cypripedium pubescens.

Portion of rhizome and rootlets, natural size.

FIG. 97.

Cypripedium parviflorum.

pubescens dry of a black-brown. Both break with a short fracture, which is white with scattered wood-bundles, have a peculiar slight but heavy odor, and a sweetish, bitter, and pungent taste.

The rhizome of *Hydrastis canadensis* is not unfrequently mixed with the commercial cypripedium; it is readily distinguished by its different shape, its yellowish-gray color externally, and by its transverse section, which is bright-yellow and shows a circular arrangement of the wood-wedges.

Constituents.—*Cypripedium* was analyzed by H. C. Blair (1866), who found a minute quantity of volatile oil, a volatile acid, two resins, tannin, starch, etc. The rhizomes of both species deserve to be again carefully analyzed.

Medical Action and Uses.—*Cypripedium* was among the medicinal plants used by the aborigines of this country, and subsequently it was resorted to by the country-people for the relief of nervous affections, such as *chorea* and *hysteria*. It is one of the numberless agents said to cure *epilepsy*. In its action and uses it is generally supposed to resemble *valerian*. The *dose* is stated to be 15 grains (Gm. 1) of the powdered root, or the equivalent of that quantity in tincture or infusion, three times a day. The oleoresin precipitated from the tincture by water may be prescribed in doses of 1 or more grains (Gm. 0.06).

DAMIANA.—DAMIANA.

Origin and Description.—Since 1874 the leaves of two or three Mexican plants have appeared in commerce under the above name, attention to the difference being called by Welles (1875). According to E. M. Holmes (1876), they come from the following species:

Turnera microphylla, *De Candolle* (Fig. 99). Nat. Ord. Turneraceæ. The leaves are alternate, obovate, entire at the base, and above on each side with three or four teeth, light-green, rather rough, and nearly smooth, or along the midrib covered with short whitish hairs. They readily fall off the much-branched stems, which, if present, have some resemblance to broom-tops. The calyx of the flowers has five three-nerved lobes, and bears in the throat five yellow obovate sepals and five stamens; the ovary has three styles, and ripens to a globular or oval one-celled and many-seeded capsule. The leaves have an aromatic taste, suggesting that of confection of senna. Leaves of the shape seen in Fig. 98 belong either to a variety of the same or to a closely-allied species. They are usually of a darker green, smooth, and have a somewhat mint-like flavor. *Turnera aphrodisiaca*, *Ward*, is the name given to the plant, in allusion to its asserted properties. *Turnera diffusa*, *Ward*, has rather shorter leaves, which are finely hairy above and tomentose beneath.

Aplopappus (*Haplopappus*) *discoideus*, *De Candolle*. Nat. Ord. Compositæ. The leaves are lanceolate, above with about three sharp teeth on each side, the lower half entire, rather coriaceous, roughish on the surface, light-green, with occasional black dots, and with minute resin-like granules or scales. The flowers, which are usually present, have an imbricated involucre, yellow florets, and a white hairy pappus. The drug has a distinct balsamic odor and taste. Dr. Rothrock (1876) gives the following synonyms

FIG. 98.

FIG. 99.

FIG. 100.

Damiana, natural size.

for this plant : *Linosyris mexicana*, *Schlechtendal*; *Baccharis veneta*, *Kunth*; and *Bigelovia veneta*, *Gray*.

The two genera mentioned above belong to Western North America and parts of South America. A species of *Turnera*, *T. ulmifolia*, *Limé*, grows in the West Indies, where its aromatic leaves and flowers have been used for their tonic properties.

Constituents.—*Turnera damiana* yielded to H. B. Parsons 8 per cent. of volatile oil, with soft resin and chlorophyll, 7 per cent. of a bitter substance, 6.4 per cent. of hard resin, and 3.5 per cent. of tannin, the remainder being sugar, gum, albuminoids, etc., with 8.4 per cent. of ash. In making a fluid extract of the *Aplopappus damiana*, and using 76 per cent. alcohol, crystals of chloride of potassium were obtained by Prof. Wayne (1876).

Medical Action and Uses.—*Damiana* appears to have stimulant, tonic, and laxative properties, and has been supposed especially to stimulate the pelvic organs. It has been widely and boldly advertised as a remedy for *sexual impotence* or indifference in either sex, but there is not the slightest reason for confiding in this statement of its virtues. Still less can it be credited with the restoration of an atrophied testis to its normal size and function, which has been set to its account. It is best administered in a fluid extract, of which the average dose is $\frac{1}{2}$ fluidrachm (Gm. 2).

DECOCTA, U. S., P. G.

Decoctions, E.; *Décoctés*, *Tisanes par décoctions*, Fr.; *Abkochungen*, G.

When the active principles of vegetable drugs are exhausted by boiling with water decoctions are obtained. Such preparations are obviously not adapted to drugs the activity of which depends upon principles of a resinous nature which are insoluble in water, nor to such as contain volatile oils or other volatile substances which would be dissipated with the vapor of water. Formerly, decoctions were usually made by using a large quantity of water and boiling it down to one-half or even to a less amount. No obvious advantage was gained by this method, and in many instances it proved to be decidedly disadvantageous, owing to the alteration and darkening of the extractive matters, and in some cases to changing the nature of the active principles. The pharmacopœias have very properly, in nearly all cases, reduced the time of boiling to 10 or 15 minutes, the general directions given by the present U. S. P. being as follows: "An ordinary decoction, the strength of which is not directed by the physician nor specified by the pharmacopœia, shall be prepared by the following formula: Take of the substance, coarsely comminuted, 10 parts (360 grains or 24 Gm.); water a sufficient quantity, to make 100 parts (3600 grains or 240 Gm., or 8 fluidounces). Put the substance into a suitable vessel provided with a cover, pour upon it 100 parts of cold water, cover it well, and boil for 15 minutes; then let it cool to about 45° C. (113° F.), strain the liquid, and pass through the strainer enough cold water to make the product weigh 100 parts.

Caution.—The strength of decoctions of energetic or powerful substances should be specially prescribed by the physician."

By following the directions of the P. G., to keep the mixture of drug and cold water for half an hour in a bath of steam arising from boiling water, the time is practically still more reduced; the proportion of very mucilaginous drugs to be used in a decoction is left to the dispenser; but the physician is required to state the quantity of such drugs for which a maximum dose is given by the pharmacopœia; other drugs may be used in the proportion of 1 part for 10 parts of decoction.

The use of cold water to begin with ensures the complete exhaustion from the drug of all its soluble principles by the gradually-heated water, the albuminous principles being subsequently coagulated as the heat is increased to near the boiling-point. If, on the other hand, the drug be at once immersed in boiling water, the albumen contained in cells would be coagulated, and thus seriously interfere with the extraction of the other principles. In preparing compound decoctions all the drugs may be added to the cold water, with the exception of those which, like senna, are injured by long-continued heat or which contain aromatic or other volatile principles. Such should be added when the decoction is ready to be removed from the fire or steam-bath, and allowed to digest until it is sufficiently cooled for straining. The material should in all cases be cut or bruised, the degree of fineness depending upon the nature of its tissue. Woody drugs may be

reduced to a moderately fine powder; leaves, however, and other drugs consisting mainly of loose parenchyma, are better used in the form of a moderately coarse or very coarse powder.

Unless the liquid is to be considerably boiled down, decoctions are best prepared in a vessel provided with a cover which may be loosely put on until the boiling is completed, when the vessel should be well closed, particularly if additions have been made at the close of boiling. Porcelain is undoubtedly the best material for vessels used for preparing decoctions, since it is not acted upon by the various vegetable principles; for similar reasons glass flasks will answer a useful purpose in making small quantities of these preparations. As a rule, it is best to avoid metallic vessels, except when made of block-tin and used in connection with a steam-bath. As many drugs contain tannin, vessels made of iron are not adapted for preparing their decoctions, and the usually imperfect covering of galvanized (or zinc) or tinned sheet iron renders the vessels lined with such material but little better suited for this purpose, and still inferior to properly-enamelled iron vessels.

As a rule, decoctions should be allowed to cool to below 50° C. (122° F.) before they are strained; principles which are soluble only in hot water are then mostly precipitated, and removed without, in most cases, weakening the medicinal effects of the preparations. But even with this precaution the strained liquid may become unsightly in appearance by the further deposition, on cooling, of apotheme or matter soluble only in hot water. In such cases the pharmacist should be guided by the directions of the pharmacopœia or by the intentions of the physician, and not sacrifice effect to elegance. With some exceptions, decoctions which were formerly made at the house of the patient have gradually fallen into disuse through the introduction of fluid extracts and similar permanent preparations, by which the medicinal properties can be preserved unaltered for months, or even years, while decoctions cannot be depended upon for more than one or, at the utmost, a few days.

DECOCTUM ALOES COMPOSITUM, *Br.*—COMPOUND DECOCTION OF ALOES.

Tisane (Décocté) d'aloès composée, Fr.; Zusammengesetztes Aloedecoct, G.

Preparation.—Take of Extract of Socotrine Aloes 120 grains; Myrrh, Saffron, each 90 grains; Carbonate of Potash 60 grains; Extract of Liquorice 1 ounce; Compound Tincture of Cardamoms 8 fluidounces; Distilled Water a sufficiency. Reduce the extract of aloes and myrrh to coarse powder, and put them, together with the carbonate of potash and extract of liquorice, into a suitable covered vessel with a pint of distilled water; boil gently for 5 minutes, then add the saffron. Let the vessel with its contents cool, then add the tincture of cardamoms, and, covering the vessel closely, allow the ingredients to macerate for 2 hours; finally, strain through flannel, pouring as much distilled water over the contents of the strainer as will make the strained product measure 30 fluidounces.—*Br.*

The alkaline carbonate is added for the purpose of aiding the solution of the resinous principles of aloes and myrrh; the tincture of cardamom, saffron, and liquorice act as correctives, the latter serving more especially for partially covering the nauseous taste of the aloes.

Medical Action and Uses.—The active agents in this preparation are essentially the same as are in the tincture of aloes and myrrh. It is a useful purgative in numerous cases for which the alcoholic preparation just named would be too stimulating; and it is probable that the permanent solution of its ingredients renders its purgative operation milder—an effect which is enhanced by the liquorice and cardamom it contains. It is an appropriate medicine when purgation is indicated in *amenorrhœa* due to an atonic state of the system, or simply in constipation with a tendency to hæmorrhoidal engorgement. Like the tincture, it is much less used than the corresponding pill (*Pilula aloes et myrrhæ*), but it may be prescribed in doses of from $\frac{1}{2}$ fluidounce to 2 fluidounces (Gm. 15–60).

DECOCTUM CETRARIE, *U. S., Br.*—DECOCTION OF CETRARIA.

Decoction of Iceland moss, E.; Tisane (Décocté) de lichen d'Islande, Fr.; Isländisch-Moos-Absud (Decoct), G.

Preparation.—Cetraria 5 parts (360 grains or 24 Gm.); Water a sufficient quantity; to make 100 parts (7200 grains or 240 Gm., or 16 fluidounces). Cover the cetraria, in

a suitable vessel, with 40 parts ($6\frac{1}{2}$ fluidounces) of cold water; express after half an hour, and throw away the liquid. Then boil the cetraria with 100 parts of water for half an hour, strain, and add enough cold water, through the strainer, to make the product weigh 100 parts.—*U. S.*

The decoction of the *Br. P.* is identical with this, 1 ounce av. of Iceland moss being used for 1 Imperial pint of decoction; the boiling is continued for 10 minutes only, which is ample for the purpose. The tisane of the *Fr. Cod.* is made in the proportion of 1 to 100.

Medical Uses.—This is the best form for administering Iceland moss. It retains the bitter principle as well as the demulcent elements of the moss, and it is on the former that the therapeutical qualities of that substance chiefly depend. It should be taken in doses of from 2 to 4 ounces (*Gm.* 60–130) three or four times a day.

DECOCTUM CINCHONÆ FLAVÆ, *Br.*—DECOCTION OF YELLOW CINCHONA.

Decoction chinæ regiz.—*Tisane (Décocté) de quinquina jaune, Fr.; Königschina-Absud, G.*

Preparation.—Take of Yellow Cinchona-Bark, in coarse powder, $1\frac{1}{4}$ ounces; Distilled Water 1 pint. Boil for 10 minutes in a covered vessel. Strain the decoction when cold, and pour as much distilled water over the contents of the strainer as will make the strained product measure 1 pint (Imperial).—*Br.*

If strained while hot, a turbid preparation is obtained from the deposition, after cooling, of cinchonic red and cinchotannate of the alkaloids; these insoluble compounds are removed by straining *when cold*. The whole of the alkaloids may be kept in solution by the addition of some acid.

Medical Uses.—*Dose*, 2 fluidounces (*Gm.* 60) to be repeated every 2, 3, or 4 hours in acute diseases, and three times a day before meals, as a tonic.

DECOCTUM GRANATI RADICIS, *Br.*—DECOCTION OF POMEGRANATE-ROOT.

Decoction corticis radicis granati.—*Tisane (Décocté) d'écorce de la racine de grenadier, Fr.; Granat-Wurzel-Rinden-Absud, G.*

Preparation.—Take of Pomegranate-Root Bark, sliced, 2 ounces; Distilled Water 2 pints. Boil down to a pint and strain, making the strained product up to a pint (Imperial), if necessary, by pouring distilled water over the contents of the strainer.—*Br.*

The tissue of the bark is not firm enough to require so long-continued a boiling.

Medical Uses.—This decoction may be used for all the purposes to which vegetable astringents of moderate power are applied, such as passive hæmorrhages and mucous and serous profluvia, as a wash for open sores accompanied with a profuse discharge, for relaxed states of the mouth, vagina, rectum, etc. It is, however, most useful as a *tæniifuge*. (For the mode of employing it see GRANATI RADICIS CORTEX.)

DECOCTUM HÆMATOXYLI, *Br.*—DECOCTION OF LOGWOOD.

Tisane (Décocté) de bois de Campêche, Fr.; Blauholz-Absud, G.

Preparation.—Take of Logwood, in chips, 1 ounce; Cinnamon-Bark, in coarse powder, 60 grains; Distilled Water 1 pint. Boil the logwood in the water for 10 minutes in a covered vessel, adding the cinnamon toward the end. Strain the decoction, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

A longer-continued boiling of logwood in chips would improve the result of this formula.

Medical Uses.—Although this decoction may be used for most of the disorders for which vegetable astringents are indicated, it is chiefly employed internally for the relief of diarrhœa, but much less so than its cognate medicines. Its mildness adapts it to the treatment of infantile diarrhœas. The *dose* for an adult is about 2 fluidounces (*Gm.* 60); for infants and children, 1 or 2 fluidrachms (*Gm.* 4–8).

DECOCTUM HORDEI, Br.—DECOCTION OF BARLEY.

Barley-water, E. ; Tisane (Eau) d'orge perlé, Fr. ; Gerstenschleim, G.

Preparation.—Take of Pearl Barley 2 ounces; Distilled Water 1½ pints (30 ounces). Wash the barley in cold water, and reject the washings; boil the washed barley with the distilled water for 20 minutes in a covered vessel, and strain.—*Br.*

The washing of the barley with cold water is intended for the removal of extraneous matters and of any unpleasant odor and taste. Mustiness is still better removed by washing with hot water, or by boiling the barley with the water for 1 or 2 minutes and throwing this liquid away. By this time the barley will be considerably swollen, and the decoction, when completed, will be mucilaginous.

Medical Uses.—Barley-water, the most ancient of fever-drinks, continues to be the most generally employed. Highly nutritious, extremely digestible, unirritating, tending to promote the *intestinal* and *urinary* secretions, and soothing irritation in the *throat* and *air-passages*, barley seems better adapted to these purposes than rice or any other cereal. According to the state of the patient the decoction may be rendered more or less nutritious by longer or shorter boiling. If no contraindication exists it should be sweetened, and flavored with lemon-juice.

DECOCTUM PAPAVERIS, Br.—DECOCTION OF POPPIES.

Tisane de pavot, Fr. ; Mohnkapseln-Absud, G.

Preparation.—Take of Poppy-Capsules, bruised, 2 ounces; Distilled Water 1½ pints. Boil for 10 minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

The Pharmacopœia does not direct the removal of the seeds, the oil of which will to some extent remain suspended in the mucilaginous liquid.

Medical Uses.—This preparation possesses slight anodyne virtues, and is also emollient in consequence of the oil and mucilage it contains. It has, however, no demonstrable advantage over preparations of flaxseed, slippery elm, and many mucilaginous substances to which oil or glycerin and laudanum have been added. This remark applies particularly to its use in poultices and fomentations.

DECOCTUM PAREIRÆ, Br.—DECOCTION OF PAREIRA.

Tisane de pareira brava, Fr. ; Pareirawurzel-Absud, Grieswurzel-Absud, G.

Preparation.—Take of Pareira-Root, sliced, 1½ ounces; Distilled Water 1 pint. Boil for 15 minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

Medical Uses.—(For the action and uses of this preparation see PAREIRA.) The *dose* of the decoction is 1 or 2 fluidounces (Gm. 30–60) three or four times a day.

DECOCTUM QUERCUS.—DECOCTION OF OAK-BARK.

Tisane (Décocté) d'écorce de chêne, Fr. ; Eichenrinden-Absud, G.

Preparation.—Take of Oak-Bark, bruised, 1½ ounces; Distilled Water 1 pint. Boil for 10 minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

The tannin is readily extracted by the boiling water, and the strained liquid will cause precipitates with most salts of the heavy metals, with solutions of alkaloids, etc. Alkaline liquids will hasten the decomposition of the astringent principles.

Medical Uses.—This preparation is seldom administered internally, but may be used to restrain passive *hæmorrhages* and *chronic fluxes* of the bowels and bronchia. Externally, it is sometimes employed to control *bleeding* and also *suppuration*, and to diminish excessive local *sweats*, but more frequently to constrict relaxed mucous membranes and lessen their secretion, as in cases of *flaccidity of the urethra*, *pharynx*, or *larynx*, *prolapsus of the rectum*, *hæmorrhoids*, and *leucorrhœa*. It may be used to promote contraction of the *relaxed skin* of the abdomen, scrotum, etc.; to prevent the formation of *bed-sores* and the chafing of surgical apparatus; to heal flabby and ill-conditioned *ulcers*;

to restrain *gangrene* and prevent its fœtor; and finally, in a bath, to counteract extreme relaxation of the general integument. The *dose* of this decoction is 2 fluidounces (Gm. 60). For external purposes a decoction of twice the official strength is preferable.

DECOCTUM SARSÆ, Br.—DECOCTION OF SARSAPARILLA.

Decoctum sarsaparillæ.—*Tisane de salsepareille*, Fr.; *Sarsaparilla-Absud*, G.

Preparation.—Take of Jamaica Sarsaparilla, cut transversely, 2½ ounces; boiling Distilled Water 1½ pints. Digest the sarsaparilla in the water for an hour, then boil for 10 minutes in a covered vessel, cool and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint (Imperial).—*Br.*

The formula is an improvement on the older ones, by which long-continued boiling was directed. The French preparation is made from 6 parts of sarsaparilla to 100 of liquid, by first macerating, then heating to boiling, and finally digesting for 2 hours.

Medical Uses.—The purpose of this preparation is the administration of sarsaparilla without the associate ingredients of the compound decoction. It is, however, very little used. Its *dose* is from 2 to 4 fluidounces (Gm. 60–120) three or four times a day.

DECOCTUM SARSAPARILLÆ COMPOSITUM, U. S., P. G.—COMPOUND DECOCTION OF SARSAPARILLA.

Decoctum sarsæ compositum, Br.—*Tisane (Apozème) sudorifique, Décocté de salsepareille composé*, Fr.; *Zusammengesetztes Sarsaparilla-Decoct*, G.

Preparation.—Sarsaparilla, cut and bruised, 10 parts (5 oz. av.); Sassafras, in No. 20 powder, 2 parts (1 oz. av.); Guaiacum-Wood, rasped, 2 parts (1 oz. av.); Glycyrrhiza, bruised, 2 parts (1 oz. av.); Mezereum, cut and bruised, 1 part (½ oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. av. or 48 fluidounces). Boil the sarsaparilla and guaiacum-wood for half an hour in a suitable vessel with 100 parts of water; then add the sassafras, glycyrrhiza, and mezereum; cover the vessel well, and macerate for 2 hours; finally strain, and add enough cold water, through the strainer, to make the product weigh 100 parts.—*U. S.*

Take of Jamaica Sarsaparilla, cut transversely, 2½ ounces; Sassafras-Root, in chips, Guaiacum-Wood turnings, Fresh Liquorice-Root, bruised, each ¼ ounce; Mezereon-Bark 60 grains; boiling Distilled Water 1½ pints. Digest the solid ingredients in the water for an hour, then boil for 10 minutes in a covered vessel, cool and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint (Imperial).—*Br.*

Much of the oil of sassafras is lost by boiling; the first formula is therefore an improvement upon the old one, and has been constructed upon that of the French Codex, which directs boiling 3 parts of sarsaparilla and 6 parts of guaiacum-wood with 100 parts of water, then adding 1 of sassafras and 2 of liquorice-root, and macerating for 2 hours. It will be observed that this last is much the weaker preparation, and that mezereon-bark is not used in it. The first two are simplified formulæ for the *Lisbon diet-drink* or *Decoctum lusitanicum*, which was formerly much employed. The latter may also be said of *Zittmann's decoction*, of which a *stronger* and a *milder* one are used together. *Decoctum Zittmanni fortius*: Take of sarsaparilla-root, cut, 100 parts; digest in water 2600 parts for 24 hours, and add, enclosed in a linen bag, powdered sugar and alum, each 6 parts, calomel 4 parts, and cinnabar 1 part; then heat in a covered vessel placed in a steam-bath for 3 hours, stirring frequently, and near the end of the boiling add anise and fennel, bruised, each 4 parts, senna, cut, 24 parts, and liquorice-root, cut, 12 parts. Express, strain, set aside for some time, and decant to obtain 2500 parts of clear liquid. 2500 Gm. of this are to be divided into 8 parts. *Decoctum Zittmanni mitius*: Take the residue left from the preceding and 50 parts of sarsaparilla, heat with water 2600 parts for 3 hours in a covered vessel placed in a steam-bath, stirring frequently, and when near the end of boiling add lemon-peel, Chinese cinnamon, cardamom, and liquorice-root, each, cut and bruised, 3 parts. Express and operate as before to obtain 2500 parts.—*P. G.* 1872. The present Pharmacopœia omits for the strong decoction cinnabar and calomel, and orders of sugar, alum, and the aromatics each 5 parts, senna 25 and liquorice-root 10 parts; for the weak decoction the expressed residue is omitted, and 5 parts each of the flavoring ingredients are ordered.

Medical Uses.—The virtues of the preparation are chiefly due to sarsaparilla and

mezereon, slightly reinforced by the sassafras, which, with the liquorice, serves to mask the acrid flavor of the mezereon. It is chiefly employed in the treatment of chronic *rheumatism*, *scrofula* of the bones, chronic *cutaneous diseases*, and, above all, constitutional *syphilis*. Whatever good it effects is mainly due to its promoting the secretions of the skin and kidneys. (See SASSAPARILLA.) The *dose* is 4 or 5 fluidounces (Gm. 130–160) three or four times a day.

DECOCTUM SCOPARII, *Br.*—DECOCTION OF BROOM.

Tisane de genêt à balais, Fr.; *Besenginster-Absud*, G.

Preparation.—Take of Broom-Tops, dried, 1 ounce; Distilled Water 1 pint. Boil for 10 minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

Medical Uses.—The decoction of broom is apt to excite irritation of the kidneys and urinary passages, and decidedly to increase the quantity of urine. It is the best form in which broom can be administered for the removal of *dropsical effusions*. It should be given in doses of 2 fluidounces (Gm. 60) repeated at intervals, so that from half a pint to a pint (Gm. 250–500) may be taken during the day. A compound decoction may be prepared by boiling broom-tops, dandelion, and juniper-berries, of each $\frac{1}{2}$ ounce, in $1\frac{1}{2}$ pints of water to a pint. *Dose*, 1 or 2 fluidounces (Gm. 30–60).

DECOCTUM TARAXACI, *Br.*—DECOCTION OF DANDELION.

Tisane de pissenlit, Fr.; *Löwenzahnwurzel-Absud*, G.

Preparation.—Take of dried Dandelion-Root, sliced and bruised, 1 ounce; Distilled Water 1 pint. Boil for 10 minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

Dandelion-root, if properly cut and bruised, is readily extracted by hot water.

Medical Uses.—This preparation represents all the virtues of taraxacum, and is the most suitable mode of exhibiting the medicine. As it is apt to ferment, it should be freshly made when used. The *dose* is 2 or 3 fluidounces (Gm. 60–90), and should be taken about half an hour before meals. Its efficacy is increased by simple bitters, such as gentian and columbo, or by a little orange-peel added near the end of ebullition.

DECOCTUM ULMI, *Br.*—DECOCTION OF ELM-BARK.

Décocté d'orme, Fr.; *Ulmenrinden-Decoct*, G.

Preparation.—Take of Elm-Bark, cut in small pieces, $2\frac{1}{2}$ ounces; Distilled Water 1 pint. Boil for 10 minutes in a covered vessel, then strain and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint (Imperial).—*Br.*

Medical Uses.—The decoction of this elm-bark is mucilaginous, bitter, and astringent. It is probably not much used in this country. The *dose* is from 2 to 4 fluidounces (Gm. 60–120).

DIGITALIS, *U. S.*—DIGITALIS.

Digitalis folia, *Br.*; *Folia digitalis*, *P. G.*—*Digitalis-leaves*, *Foxglove-leaves*, *E.*; *Feuilles de digitale pourprée (de grande digitale)*, *Fr.*; *Fingerhutkraut*, *G.*

The leaves of *Digitalis purpurea*, *Linké* (*D. tomentosa*, *Link et Hoffmann*). Woodville, *Med. Bot.*, plate 24; Bentley and Trimen, *Med. Plants*, 195.

Nat. Ord.—Scrophulariaceæ.

Origin.—Foxglove is a biennial plant indigenous to Southern and Central Europe, particularly in the western section, and grows wild as far north as Norway, likewise in Madeira and the Azores. It is found on the edges of woodlands and thickets in rather sandy soil, and is generally absent from calcareous districts. It is well known as an ornamental garden-plant. The stem is 2 to 5 feet (0.6 to 1.5 M.) high, has alternate leaves, and a long terminal raceme of handsome purplish-crimson and tubular bell-shaped flowers, producing an ovoid glandular pubescent capsule with numerous small seeds. The leaves, which on drying diminish in weight about 75 per cent., should be collected from

wild plants growing in mountainous regions when about two-thirds of the flowers are expanded; the leaves of plants grown in plains proved to be less active, according to W. Mayer (1880) and others. F. Schneider (1869) found the radical leaves collected in September of the first year to be very efficacious.

Description.—The radical leaves are 6 to 12 inches (15 to 30 Cm.) long, ovate or oblong-ovate, rather obtuse, at the base contracted into a winged petiole 4 to 6 inches (10 to 15 Cm.) long. The margin is rather irregularly doubly crenate, the upper surface is wrinkled, dull-green, and soft-downy; the lower surface is of a grayish color, densely pubescent and prominently reticulate; the midrib is broad toward the base, and of a slight purplish tint. The stem-leaves are gradually reduced in size and upon shorter petioles, the uppermost being sessile, oblong-lanceolate, and obscurely crenate. The dried leaves have a faint tea-like odor and a bitter rather disagreeable taste. In cultivation the plant usually becomes less hairy, and the radical leaves of the first year's growth are usually narrower and more oblong-lanceolate in outline. The following reactions may be used for determining the absence of leaves containing tannin, and the presence of a proper amount of digitalin:

"The infusion, prepared with 10 parts of boiling water, should be of a brownish color, of an acid reaction, of a peculiar odor, and of a nauseously bitter but not aromatic taste; it should on the addition of ferric chloride acquire a darker color, and after several hours a brown precipitate (absence of leaves containing tannin, giving blue-black or black-green precipitates); on dropping tannin solution into the infusion a copious precipitate should be produced, which is with difficulty dissolved by an excess of tannin; the same infusion, diluted with 3 parts of water, should, on the addition of tannin, become turbid (digitalin-tannin)." —*P. G.*

Constituents.—The medicinally active principle has been named digitalin, and is described below.

DIGITALINUM, Br.—Digitalin, *E. G.*; Digitaline, *Fr.*—The following directions are given for its preparation: Take of Digitalis-Leaf, in coarse powder, 40 ounces; Rectified Spirit, Distilled Water, Acetic Acid, Purified Animal Charcoal, Solution of Ammonia, Tannic Acid, Oxide of Lead, in fine powder, and Pure Ether, of each a sufficiency. Digest the digitalis with a gallon of the spirit for 24 hours at a temperature of 120° F.; then put them into a percolator, and when the tincture has ceased to drop pour a gallon of spirit on the contents of the percolator, and allow it slowly to percolate through. Distil off the greater part of the spirit from the tincture, and evaporate the remainder over a water-bath until the whole of the alcohol has been dissipated. Mix the residual extract with 5 ounces of distilled water, to which $\frac{1}{2}$ ounce of acetic acid has been previously added, and digest the solution thus formed with $\frac{1}{2}$ ounce of purified animal charcoal; then filter, and dilute the filtrate with distilled water until it measures a pint. Add solution of ammonia nearly to neutralization, and afterward add 160 grains of tannic acid dissolved in 3 ounces of distilled water. Wash the precipitate that will be formed with a little distilled water; mix it with a small quantity of the spirit and $\frac{1}{2}$ ounce of the oxide of lead, and rub them together in a mortar. Place the mixture in a flask, and add to it 4 ounces of the spirit; raise the temperature to 160° F., and keep it at this heat for about an hour; then add $\frac{1}{2}$ ounce of purified animal charcoal; put it on a filter, and from the filtrate carefully drive off the spirit by the heat of a water-bath. Lastly, wash the residue repeatedly with pure ether.—*Br.*

The process of the U. S. P. 1870 was nearly identical with the foregoing. Thus prepared, digitalin forms a white or yellowish-white powder, or it may be obtained in porous mammillated masses or scales. It is inodorous and has an intensely bitter taste; is soluble in alcohol, but almost insoluble in water and in ether. It dissolves slightly in dilute

FIG. 101.

Digitalis purpurea, Linne: leaf of the first and of the second year's growth.

acids without neutralizing them; its solution in concentrated hydrochloric acid is yellowish, but rapidly becomes green, and after some time deposits a green powder. Its dust is irritating and sternutatory. Heated upon platinum-foil, it burns with a sooty flame, finally leaving no residue. The readiness with which the active principle of digitalis as it exists in the plant is altered has been repeatedly pointed out. The properties given by both the British and former United States Pharmacopœias are those mentioned by Homolle (1844) and Quevenne, and by the French Codex for a digitalin prepared, according to Homolle's process, by precipitating gummy and coloring matter from the cold prepared aqueous infusion with subacetate of lead, removing the excess of lead by carbonate of sodium, precipitating with tannin, and treating further in a manner somewhat similar to the preceding process. But the process adopted by the Br. P. is that of O. Henry (1845), which yields a different product. Lefort (1864) pointed out that two kinds of digitalin are in the market—namely, *French or insoluble digitalin*, which is that of Homolle; and *German or soluble digitalin*, which is readily soluble in water, also in concentrated hydrochloric acid, the solution becoming yellow, brown, and finally a dull green; exposed to the vapor of hydrochloric acid, it turns brown, while insoluble digitalin turns green. Soluble digitalin is made in Germany by processes analogous to that of Henry, and by modifications as suggested by G. F. Walz in his investigations of digitalis (1851 to 1858). Kosmann (1875) endeavored to explain the discrepant results as follows: The active principle of digitalis, which is freely soluble in water, has been named by various authors *digitosolin*, *digitaletin*, *digitalein*, and *digitalin*; it exists in the leaves and seeds, is $C_{27}H_{45}O_{15}$, a compound of 1 molecule of digitalretin and 2 of glucose, and is readily altered even in the plant by saline and acid bodies, and converted into glucose and *insoluble digitalin* (*digitaletin* of Walz), which is $C_{21}H_{33}O_9$, and represents 1 molecule each of digitalretin and glucose. Both digitalins are very bitter and energetic medicinal agents. By the further action of hot dilute acids insoluble digitalin is split into glucose, and *digitalacetin* (*paradigitalretin*), $C_{15}H_{25}O_5$, which is slightly bitter, is soluble in alcohol, slightly so in ether, but insoluble in water and alkalies. The continued action of dilute acids results in the production of *dehydrated digitalretin*, $C_{15}H_{21}O_3$, which is resin-like, insoluble in water, soluble in alcohol, ether, and ammonia-water, and has an acrid taste; it has likewise been called *paradigitalein*. Kosmann considers Nativelle's *crystallized digitalin* as being intermediate in composition between insoluble digitalin and digitalretin.

Nativelle's process (1874) is as follows: 1000 Gm. of powdered digitalis-leaves are macerated for 24 hours in a solution of 250 Gm. of acetate of lead in 1000 Gm. of water, then displaced with 50 per cent. alcohol, the percolate treated with 40 Gm. of sodium bicarbonate, and distilled and evaporated to 2000 Gm.; when cool it is mixed with 2000 Gm. of water, and after several days decanted. The precipitate is drained, pressed, mixed with 1000 Gm. of 80 per cent. alcohol, and heated to boiling; 10 Gm. of neutral lead acetate are added, the boiling continued for a few minutes, and when cool the liquid is filtered. The filtrate is mixed with 50 Gm. of powdered wood-charcoal, and distilled, the charcoal exposed to expel the alcohol, drained, dried, and percolated with chloroform. The impure digitalin left on evaporation is dissolved in 100 Gm. of 90 per cent. alcohol, the solution mixed with a concentrated solution of 1 Gm. of lead acetate and with 10 Gm. of granular animal charcoal, boiled for a few minutes, cooled, filtered, and distilled. The granular crystals are drained, dissolved in 10 Gm. of hot alcohol; 5 Gm. of ether and 15 Gm. of water are added, and the whole well shaken together. The ether removes a colored fixed oil, and crystalline digitalin is deposited, which, if necessary, is again subjected to the same process of purification. It crystallizes from hot alcohol in the form of white slender brilliant needles.

A *digitalin* obtained from the seeds was found by Delffs (1858) to have the composition $C_{17}H_{30}O_7$, and to be colorless, crystalline, readily soluble in alcohol, ether, or chloroform, and not colored by concentrated mineral acids. Schmiedeberg (1875) obtained *digitoxin*, another active principle, from the leaves previously exhausted by water; it is entirely insoluble in water, benzol, or carbon bisulphide, very sparingly soluble in ether, slowly soluble in chloroform, and readily in alcohol, and crystallizes from the saturated solution in hot spirit of chloroform; its solutions are intensely bitter; its composition is $C_{31}H_{53}O_7$. It is not a glucoside, but acids convert it into *toxiresin*, which, like digitoxin, has a powerful action on the heart. Schmiedeberg examined also a commercial digitalin made from the seeds, and found in it *digitonin*, *digitalin* (Kosmann's insoluble digitalin?), and *digitalein*. The latter is yellowish, not colored red by boiling hydrochloric acid, and freely soluble in water, yielding a frothing solution; otherwise it resembles digitalin. This compound is $C_5H_8O_2$, forms soft colorless grains, is nearly insoluble even in boiling water.

sparingly soluble in ether and chloroform, dissolves freely in alcohol, spirit of chloroform, and acetic acid, and with warm sulphuric acid strikes a yellow or yellowish-green color, turning red with potassium bromide. Digitonin, $C_{31}H_{52}O_{17}$, is colored red by boiling dilute sulphuric acid, and dissolves in alcohol, spirit of chloroform, and water, this last solution being frothing and precipitated by baryta-water, like saponin. These bodies are readily altered under various circumstances, and their relation to each other and to the active principle or principles naturally contained in the plant must be left to further careful investigation. Duffield (1868) obtained by the official process 0.8 to 0.9 per cent. of digitalin from European and American digitalis-leaves.

W. Engelhardt (1862) obtained a physiologically active volatile alkaloid from the leaves; it was also noticed by F. F. Mayer in the leaves, but not in the extract of digitalis. An acrid principle, *scaptin*, was obtained by Radig (1835) in a very impure state, and purer by Walz (1858) as *digitalacrin*. Walz (1852) separated *digitalosmin*, a pearly acrid stearopten of the odor of digitalis. Morin's (1845) *antirrhineic acid* likewise possesses some odor. The *digitoleic acid* of Kosmann and *digitaloic acid* of Walz are volatile and fatty, and probably identical. Schmiedeberg observed a yellow coloring matter which is probably identical with chrysophan.

The other constituents of digitalis are not of medicinal or pharmaceutical importance; they comprize chlorophyll, mucilage, albumen, various salts, and *inosite*, observed by Marmé (1864).

Adulterations and Substitutions are said to have occasionally occurred, but the physical characters of digitalis-leaves are so marked that they cannot easily be confounded with other leaves, even if they are in a broken condition; the rugose upper surface, the crenate margin, and the densely-pubescent lower surface, with its well-defined meshes of white prominent veins, are not met with in any other officinal leaf. As accidental impurities have been mentioned the nearly smooth leaves of *Digitalis ochroleuca*, *Jacquin*, the stellately hairy and mucilaginous leaves of species of *Verbascum*, and the nearly entire, obscurely reticulate, and (upon the upper side) rough leaves of *Conyza squarrosa*, *Limé* (s. *laula Coniza*, *De Candolle*), and *Symphytum officinale*, *Limé*.

Physiological Action.—*On Plants and Animals*: Plants watered with an infusion of digitalis wither and die. Fish placed in a weak infusion of the plant die in spasm, with the ventricle of the heart contracted. Digitalin used hypodermically in frogs occasions a tetanoid rigidity of the muscles and an irregular tonic contraction of the heart, with slowness and unsteadiness of its rhythm. The auricle does not seem to participate in this action of the ventricle, but becomes distended as the capacity of the ventricle diminishes. At the same time the pulse-rate declines and the blood-pressure increases. But if the dose of digitalin has been directly poisonous, the pulse-rate rises and the blood-pressure diminishes. Toxical doses of digitalis given to birds, dogs, and other animals occasion active intestinal irritation, with watery or bloody dejections. Carnivorous animals are, more readily than the herbivorous, poisoned by this agent.

The action of poisonous doses of digitalis and its preparations upon the circulatory system, as illustrated by experiments upon animals, is shown first by an increase usually both of the rate and force of the pulse, while the action of the heart is strong and abrupt, and perhaps accompanied by a murmur. But sometimes the primary operation reduces the number of pulsations while augmenting their force. There is no evidence that the volume of the pulse is increased; on the contrary, it denotes the circulation of a diminished amount of blood, and is due to a tonic contraction of the ventricle, which finally arrests the circulation. Indeed, experimental investigation has demonstrated that large doses of digitalin produce a marked contraction, and even a complete closure, of the capillary vessels—a condition which necessarily involves an increased blood-pressure in the larger arteries; a conclusion confirmed by the experiments of Donaldson and Stevens (*Med. News*, xli. 697). At the same time, the heart's diastole is lengthened, it may be to fourfold the normal duration; and this it is that causes the characteristic retardation or infrequency of the pulse. Meanwhile, the auricle does not participate in the contraction affecting the ventricle, but becomes distended by the accumulated blood. The mechanism of these effects is explained to be a primary stimulation and a subsequent paralysis of the inhibitory nerve of the organ, and irritation of the motor nerves.

Later researches have not materially changed the conclusions now stated. The results of different experimenters differ, as in most other cases; thus, according to some, the

auricle as well as the ventricle is contracted in death, while the greater number state that the auricle is distended, but the ventricle contracted. The latter act appears to be the result of a gradual and progressive movement, which has been compared to peristalsis. It also is shown that while repeated small doses of digitalis cause a persistent slowing of the heart, large ones directly accelerate it (Chappet, *Contribution à l'étude de la digitale*, 1879; Cadeat, *Bull. de thérap.*, xevi. 558; F. Williams, *Arch. exper. Pathol., etc.*, xiii. 8; Leyden, *Zeitschr. f. klin. Med.*, iii. 559; Kaufmann, *Bull. de thérap.*, ci. 191).

Digitalis is held to act on the vaso-motor centre, and thus to produce contraction of the peripheral arterioles. In exceptional cases, after a lethal dose of digitalin the heart is found in diastole, and will not contract under the strongest galvanic stimulus; but, in general, when animals are killed by digitalis or by digitalin the heart is found strongly contracted. If, before death, aconite is duly administered, it will delay the fatal event, or perhaps prevent it altogether; for aconite tends to relax the heart-muscles, and in animals killed by it the heart is found in diastole. Respiration follows the circulation in its changes, becoming infrequent when the pulse is slow and hurried when the pulse is rapid. The temperature of the body is not materially affected, nor uniformly in the same manner. The preceding statement of the physiological action of digitalis was originally summarized by Niemeyer, who said that "it fills the arteries by emptying the veins." Fothergill finds in his own experiments, observations, and reasonings sufficient confirmation of this view. But the inquiry naturally suggests itself: If the whole arterial system, from the left ventricle of the heart to the systemic capillaries, is in a state of tonic contraction, must not the blood accumulate in the venous system and overload it? But as it evidently does not accumulate there, but, on the contrary, is prevented from so accumulating by digitalis, the mechanism by which the medicine maintains the balance of the circulation would seem to involve some other factor. This may possibly be the increased propulsive power with which the blood passes from the arteries into the veins; so that, although the amount of blood in the arteries is actually diminished and that in the veins increased, yet the rate of movement of the blood-current due to the arteries themselves may be so much accelerated as to overcome infarctions and prevent effusions. The intrinsic diuretic action of digitalis seems to have been asserted by nearly all the early experimenters, but more prolonged and accurate observations prove that no such operation belongs to it.

Extract of *Adonis vernalis* is stated by Bubnoff to act upon frogs in a manner similar to digitalis—*i. e.* by producing a tonic contraction of the ventricle.

On Man: The symptoms produced by digitalis have been described in substantially the same terms by nearly all observers. The following summary, by Koppe, is complete in its details: In about an hour after taking 2 Mg. ($\frac{1}{3}$ gr.) of *digitacin* he began to experience malaise, depression, faintness, nausea, and repugnance to food; in 3 or 4 hours the pulse fell from 80 to a point varying between 30 and 58; nausea was intense and indescribably distressing, and only momentarily relieved by a profuse vomiting of dark-green bile, and later of yellow bile; the pulse was intermittent, the features pale and collapsed. In 7 or 8 eight hours prostration was so extreme that without assistance it was impossible to stand; vision was so confused by an indefiniteness of outline that familiar objects and persons were not recognized, but the latter were known by their voices, and the whole field of vision was yellow. During the night bilious vomiting recurred at intervals, and was excited even by iced champagne. The following day the same symptoms continued; the pulse was 54 and intermittent, with a sense of precordial sinking, and the sphygmographic tracing showed diminished force of the pulse, with inequality. The second night was disturbed with restlessness and nightmare. On the third day small quantities of water were retained, but the vision and the pulse remained as before. It was not until the fourth day that the experimenter was able to walk leaning on a friend's arm, and that the disorder of vision gradually subsided; sleep, which now was refreshing, and an almost voracious appetite, enabled him speedily to renew his strength (*Archiv f. exp. Pathol.*, iii. 289). In other cases in which digitalis or digitalin has been taken in excessive doses the symptoms were essentially the same as these.

Some points of diversity were observed in the following cases: A young man took 13.7 Gm. of digitalis-leaves (about 3 drachms) within 4 weeks; he suffered from severe gastric catarrh, dysphagia, and singultus, and died suddenly while standing (*Edin. Med. Jour.*, xxii. 180). A woman took 15 Mg. (gr. $\frac{1}{2}$) of digitalin; there was abundant urination, and in the course of 14 hours cramps in the legs; the pulse was usually 104, and at no time below 60 (*Philad. Med. Times*, iv. 506). A woman took 14 Mg. (gr. $\frac{1}{2}$) of digitalin on one day and 60 Mg. (gr. j) the following day. Violent pains affected the head

and stomach, the pulse was 40 and very feeble, and there was almost complete suppression of urine (*ibid.*, viii. 417). A man took an infusion of 640 grains of digitalis. Two days after the more usual symptoms he suffered from violent headache, hallucinations of light, and aphasia that continued for 4 days (*Med. Record*, xxiv. 489). In several cases an erysipelatoid eruption, with subsequent desquamation of the skin, has followed the internal use of digitalis, and an ointment containing the drug has caused a papular eruption.

As regards the heart, digitalis and its preparations in small doses primarily increase the pulse-rate and tension, and, if continued, lower the rate without diminishing the tension. It is an error to suppose that the increased force of the arterial blood-current, as measured by the dynamometer, denotes an increased volume of that current; on the contrary, the arteries and the heart both experience tonic contraction under the influence of digitalis, and the supply of arterial blood is everywhere diminished. That digitalis does not give a real increase of power to the heart is shown by the fact that when the pulse-rate is slowest a comparatively slight muscular exertion, such as changing the recumbent for the erect posture, will sometimes cause the pulse to rise from the lowest point reached under the influence of the medicine to one far above the normal rate. This effect, however, is said to be produced only when the tonic action of the medicine is about to be replaced by exhaustion. The tendency to rigid contraction does not affect all the heart-muscles in an equal degree, but chiefly those of the left ventricle. It is this power which in certain cases of positive or relative debility of that ventricle renders the medicine a valuable remedy while its action is maintained within certain bounds, but beyond them it tends to obstruct the cardiac circulation, and, by suddenly preventing the free passage of blood through the heart, to cause death by syncope.

Digitalis is totally destitute of direct diuretic properties. The cases which led to a belief in its possessing them were those in which a diminished secretion of urine was produced by obstructive heart disease, with positive or relative debility of that organ. In a healthy state of the heart digitalis diminishes the amount of urine secreted, as well as the proportion of solid excrementitious matter contained in it. There is no reason to suppose that by its direct operation it stimulates any one of the functions. It certainly, in doses which exhibit its physiological operation, depresses the entire nervous system, impairs the digestion, diminishes urination, lowers the animal temperature, retards the respiration, and may for a time annihilate the activity of the genital organs. Its diuretic action, which is the strongest ground of its claim to merit as a medicine, appears, then, to be altogether indirect.

Medical Uses.—As was just stated, the diuretic virtues of digitalis are the most conspicuous, and long before its mode of action had been experimentally investigated it was established as the most efficient remedy for *dropsy* depending directly upon disease of the heart and upon that form of *renal disease* which consists of congestion and tubal obstruction depending upon obstacles to the cardiac circulation. On closer examination the affections which produce dropsy by hindering the cardiac circulation, particularly *valvular obstruction*, and notably *stenosis of the mitral valve*, and positive or relative *weakness of the heart-muscle*, were found to be most readily relieved by this medicine. By rendering the action of the heart stronger, as well as more tranquil and regular, and perhaps by producing contraction of the capillary arteries, the venous congestions which directly occasion dropsy are removed, degeneration of the liver or kidneys is retarded, and the absorption of the effused liquid necessarily follows. When dropsy depends upon a congested state of the kidneys, and to the prevented escape of water through these excretories, and is cured by digitalis, the medicine probably acts by contracting the renal capillaries, and thereby lessening the engorgement which prevented their normal secretion from taking place. In general dropsy of whatever form debility of the circulation, whether it be due to cardiac embarrassment or to renal obstruction, is the essential condition for securing the diuretic operation of digitalis.

No particular lesion of the heart is by itself an indication or a contraindication for the use of digitalis; it is the phenomena which accompany, and usually are caused by, certain lesions that furnish an indication for the medicine. Nor is it indicated by mere irregularity of action due to nervous disorder of the heart itself, or to disease elsewhere acting by a reflex operation upon the heart. *Dilatation*, slight muscular *degeneration*, and *mitral obstruction* and *insufficiency* are the lesions whose effects are favorably influenced by digitalis, which increases the blood-supply to the heart itself, thereby improving its nutrition, renders the irregular heart rhythmical in its movements, and gives a tonic contractility to its flaccid muscles. But this very power is not without its danger if the weakness of the heart is excessive, especially through fatty degeneration. To slow the

heart when its muscular structure is greatly impaired is to increase its embarrassment. To slow it when its muscle is simply hypertrophied is to counteract the conservative agency by which the hypertrophy was established, as in cases of *aortic* obstruction or insufficiency, or of both united. So long as the heart's movements are not arrhythmical, or do not tend to become so during excitement of the organ, there is no indication for the use of digitalis. Whenever the rhythm of the heart is perverted, especially when its impulse is irregular in force as well as time, and this irregularity is associated with a corresponding irregularity in the duration and intensity of the murmurs and of the pulse, and when at the same time the arterial system is deficient in blood while the veins are overloaded with it, as shown by the feeble and usually irregular pulse, the dropsical limbs, the difficult breathing, the discolored face, and perhaps bloody expectoration and scanty urine, digitalis is clearly indicated. By its means the hurried pulsations are reduced to the normal rate and gain in regularity what they lose in frequency, and the dropsy, if that is present, begins to decline along with the disorder of the circulation. According to Fernet, it is usually on the third or fourth day that diuresis begins, especially in persons who have not become habituated to the drug, and continues for several, or indeed many, days after the medicine has been discontinued. It should not be resumed until either the heart falls again into disorder or the dropsical symptoms recur.

The false and absurd theory according to which the treatment of *fever* should consist of means tending directly and solely to reduce the pulse-rate has been illustrated by the use of digitalis in *typhoid fever*. Even its advocates have not shown that it abridges the disease or lessens its mortality, while it certainly tends to impair the digestion and reduce the strength, and may even occasion sudden death. The use of digitalis in other forms of fever is equally unsatisfactory, and justifies the judgment of Traube, that the true field of action for digitalis is not fever. That it is practically useful in febrile conditions with a feeble heart, as in *typhoid pneumonia* and *relapsing fever*, has been asserted (Fothergill), but has not been proved. Indeed, Liehermeister condemns digitalis in fever, both because its antipyretic operation is uncertain, and because, when it does take place, it is apt to be accompanied by disquieting symptoms. He even remarks that it can do no harm while the heart is strong (a case in which it is not needed) unless it brings on vomiting, as it often does, and should then be discontinued, but that where the heart is feeble it must be very circumspectly used. Indeed, the more frequent the pulse is in fever the less indication is there for digitalis. "A tendency to heart-paralysis is not neutralized, but rather promoted, by digitalis. It is only in an advanced stage of the attack, when the fever has subsided, and yet the pulse continues frequent and the heart weak, that an indication for digitalis arises similar to that in heart disease, and then it will reduce the frequent pulse and strengthen the heart for its work." Upon which it is sufficient to remark that food and cordials have always been found efficient in such conditions, and that they expose the patient to no possible risk, as digitalis does. The recent use of digitalis in fever is only a revival of the old application of it by Rasori to the treatment of *inflammations*; it has also been employed by some who were perhaps ignorant of the history of its vogue and of its condemnation. The results of its revival have been to prove that digitalis does not in the least modify favorably any acute inflammation, and especially *pneumonia*, *pleurisy*, and *pericarditis*, but that, on the contrary, it exposes the patient to the risk of sudden death. The only inflammatory affection in which it may be advantageously used is chronic *bronchitis* with profuse secretion, which is often confounded with consumption. There is no doubt that in this disease it has been found to lessen the pulmonary congestion and secretion, and thereby the dyspnoea, sweating, and wasting of strength which they cause. There is good reason for believing that certain forms of hæmorrhage may be controlled by digitalis, more particularly *uterine hæmorrhage*, whether due to congestion, to vascular relaxation, or to organic diseases of the uterus. Its utility in *pulmonary hæmorrhage* is less demonstrable. The mode of action of digitalis in these cases may be presumed to be analogous to that of ergot—viz. it causes a contraction of the arteries. The same mode of action may be attributed to the medicine in *delirium tremens*, in which it is reputed to be highly efficient if given in large doses, such as $\frac{1}{2}$ fluidounce (Gm. 16) of the tincture, and even as much as 28 fluidrachms (Gm. 100). More frequently, however, doses of 1 or 2 fluidrachms (Gm. 4-8), repeated every 3 or 4 hours, have been employed. It would appear that there is something in this affection which ensures a singular toleration of the medicine. But the necessity of using it at all, and thereby incurring a risk which experience has shown to be occasionally a fatal one, is not apparent in relation to a disease which nearly always recovers under judicious hygienic treatment when the patient's constitution is sound. Digitalis was formerly esteemed as a remedy

for *epilepsy*, and recently it has been used by Gowers along with belladonna to reinforce the action of the bromides, and was found by him distinctly more useful than the bromides alone (*Times and Gaz.*, April, 1880, p. 447). The anaphrodisiac virtue of digitalis has been found useful in preventing *erections of the penis* due to local irritation, and also nocturnal *seminal emissions* and other effects of genital excitement. In *poisoning by aconite* digitalis is physiologically indicated, and published cases are supposed to furnish clinical evidence of its value. A man had taken an ounce of strong tincture of aconite, had cold hands and feet, a dusky and moist skin, frothed at the mouth and nose, and was pulseless. An emetic caused vomiting and purging; 20 drops of tincture of digitalis were injected subcutaneously, and galvanism applied to the cardiac region and kept up for 20 minutes. The patient being now able to swallow, some ammonia and brandy, with a teaspoonful of tincture of digitalis, was given, and he recovered perfectly (*British Med. Jour.*, Dec. 1872, p. 680). The use of galvanism, emetics, and diffusible stimulants in this case lessens the value of the evidence in favor of digitalis. In a later case (*Boston Med and Surg. Jour.*, Oct. 1879, p. 544) of recovery under similar treatment it is stated that the hypodermic injection of 15 drops of tincture of digitalis was "followed at once by quite a decided increase in the volume of the pulse," and the patient recovered.

Digitalis has been used as a local application to promote the resolution of *enlarged glands*, and also in infusion or tincture applied to the abdomen, especially in cases of *renal dropsy*. In the former case iodine is preferable, and in the latter the medicine should rather be given internally.

Administration.—Digitalis is given in doses of 1 or 2 grains (Gm. 0.06–0.12) twice or thrice daily until its effects begin to appear, when it should be at once suspended or diminished. The infusion of the fluid extract or the tincture is preferable, and of these the first is by far the most efficient. Besides the officinal infusion, one may be prepared daily with about 3 grains (Gm. 0.20) of digitalis in about 6 ounces (Gm. 200) of hot water, sweetened, and flavored with tincture of cinnamon, bitter orange, or mint. This quantity should be given in three or four doses at regular intervals. There is no doubt that small are preferable to large doses, for if they produce their proper medicinal effects a little later, it is without risk. And it should be understood that these effects are not to be looked for for several days. Poisonous effects are to be combated by wine, opium, and strong coffee. Strychnia has been recommended as a physiological, and tannin as a chemical, antidote. If a poisonous dose has been recently swallowed, ipecacuanha, mustard, and other prompt emetics should be administered. The variable strength of *digitalin* requires that it should be used very cautiously, beginning with the minimum dose, which may be stated at gr. $\frac{1}{16}$ (Gm. 0.001). This dose may be repeated at intervals of 6 or more hours, and gradually and continuously increased, but so as not to exceed gr. $\frac{1}{8}$ (Gm. 0.01) during 24 hours.

DIOSCOREA.—WILD YAM, COLIC-ROOT.

The rhizome of *Dioscorea villosa*, Linné.

Nat. Ord.—Dioscoreaceæ.

Origin.—Wild yam is a diœcious climbing perennial growing in thickets in moist localities of the United States south to Florida and west to the Mississippi. The leaves are alternate, opposite or whorled, broadly ovate-cordate, acuminate, nine- to eleven-ribbed, nearly smooth above, downy and paler beneath. The fruit is a triangular-winged capsule growing in pendulous bunches.

Description.—The rhizome is horizontal, about $\frac{1}{2}$ inch (13 Mm.) thick, somewhat flattened above, repeatedly forked or branched and bent, 6 inches (15 Cm.) or more in length, on the lower side with distant simple wiry rootlets from 2 to 4 inches (5 to 10 Cm.) long. The rhizome is externally of a pale yellowish-brown color, and breaks with some difficulty, showing internally a compact white tissue with numerous scattered yellowish wood-bundles. It is inodorous, and has a taste at first insipid, and afterward strongly acrid. In Virginia it is known as *rheumatism-root*.

Constituents.—Wild yam contains much starch. The acrid principle has not been isolated: it appears to be gradually altered on boiling the rhizome with water.

Other Species.—Most species of *Dioscorea* which are indigenous and cultivated in the East and West Indies and in other tropical countries have large farinaceous edible tubers, which are known as *yam*. E., G.; *igname*, Fr. The following are the most important: *D. ALATA*, Linné, *White negro yam*; *D. TRIPHYLLA*, Linné, *Buck yam*; *D. TRIFIDA*, Linné, *Indian yam*; *D. BULBIFERA*, Linné, *Ceylon white yam*; and *D. SATIVA*, Linné, *Common yam*.

The smaller cylindrical tuberous rhizomes of *D. JAPONICA*, *Thunberg*, and *D. QUINQUELOBA*, *Thunberg*, are eaten in Japan. The former is about 4 inches (10 Cm.) long, farinaceous and white; the latter is smaller, externally pale-brown, internally dingy-white, and has a bitterish taste.

Medical Action and Uses.—Time has not increased our knowledge of the medicinal qualities of wild yam more than it has that of many other indigenous plants which were long ago reputed to be valuable medicines. We are therefore compelled to repeat, without addition or modification, the old-time statement that, according to Riddell, "a decoction of it is eminently beneficial in bilious colic," and that Dr. Neville "places much reliance on the tincture as an expectorant, and also that it acts as a diaphoretic, and in large doses as an emetic." In Iowa it is known as "colic-root." If these statements are correct, it may be assumed that *dioscorea* has some of the qualities of *ippecacuanha*. The resin precipitated by water from the tincture is said to produce effects analogous to those above enumerated, and has been prescribed in doses of from 1 to 5 grains (Gm. 0.06–0.30).

DIOSPYROS.—PERSIMMON, DATE-PLUM.

Fruits de plaquemini de Virginie, Fr.; *Persimmonfrüchte*, *Dattelpflaumen*, G.

The unripe fruit of *Diospyros virginiana*, *Linné*.

Nat. Ord.—*Ebenaceæ*.

Origin.—The persimmon tree is indigenous to the United States, and grows in woodlands, in low grounds, and along streams from the New England States west to Illinois, and in the Southern States. It attains a height of 50 to 60 feet (15 to 18 M.), is irregularly branched, has nearly smooth, subcoriaceous, ovate-oblong leaves, and produces in May and June axillary and solitary fertile flowers with eight stamens and clustered sterile flowers with sixteen stamens. The fruit ripens in November, but should be collected not later than October, while green.

Description.—The fruit is a globular berry about an inch (25 Mm.) in diameter, with a short foot-stalk, and the permanent four-lobed calyx at the base, green, smooth, and four- to six-celled, each cell containing a single flat ovate-oblong seed. The unripe persimmon has a short remnant of the style attached, is of a pleasant but weak odor, and contains a viscid juice of a very astringent taste, which is retained when carefully dried, but becomes acidulous-sweet after the fruit has been exposed to the frost.

Constituents.—B. R. Smith (1846) found the unripe fruit to contain tannin, malic acid, and sugar. J. E. Bryan (1860) detected also pectin, and regards the tannin as distinct from the tannin of galls. Charopin (1873), however, considers it identical with the latter, and isolated also a yellow coloring matter which is insoluble in water, but readily soluble in ether.

The ripe fruit is edible. Mixed with flour, a pleasant bread or cake is made of it. When kneaded with half its measure of wheat-bran and well baked in an oven, a bread is obtained which in the Southern States is preserved for making *persimmon beer* by fermenting it with some hops. Such beer is also made from the fresh fruit, and by distillation alcohol may be obtained.

FIG. 102.

Diospyros virginiana: fruit and transverse section, natural size.

Allied Plants.—*DIOSPYROS EMBRYOPTERIS*, *Persoon* (Bentley and Trimen, *Med. Plants*, 168). The orange-yellow fruit is about 2 inches (5 Cm.) in diameter, about ten-celled, very astringent in its unripe state, and is used in India like persimmon.

DIOSPYROS KAKI, *Linné filius*, a medium-sized tree of China and Japan, has a sweet, reddish fruit, which, preserved with sugar, is occasionally seen in our market, being sold as *Chinese or Japanese persimmon*.

Medical Action and Uses.—The unripe fruit, and also the inner bark, are astringent and bitter, and are used, like other products of the same nature, in the treatment of chronic and subacute *diarrhœa*, *leucorrhœa*, *sore throat*, and *uterine hæmorrhage*. It is also sometimes employed as a tonic and febrifuge. The most convenient preparation is an infusion or a vinous tincture, which may be made by percolation with an ounce of the dried unripe fruit or of the bark to half a pint or less of the menstruum. It may be prescribed in doses of from $\frac{1}{2}$ ounce to 2 fluidounces (Gm. 15–60).

DIRCA.—LEATHER-WOOD.

Dirca palustris, *Linne*.

Nat. Ord.—Thymelacææ.

Description.—The leather-wood, also called *moose-wood*, *rope-bark*, and in New England *wicopy*, grows in rich damp woods from South Carolina northward to Canada, and is a much-branched shrub about 4 feet (1.2 M.) high, with the branches apparently joined, and with soft white and brittle wood. The smooth yellowish-brown or brown-gray bark is very fibrous and remarkably tough, hence the common names. The leaves are alternate, about 3 inches (75 Mm.) long, subsessile, oval-obovate, acute at each end, pale-green and slightly hairy beneath. The flowers precede the leaves, are in clusters of two to four, have a light-yellow tubular funnel-shaped, four-toothed calyx, eight slender stamens, and ripen an oval, one-seeded, reddish, drupaceous fruit, which is about $\frac{1}{4}$ inch (6 Mm.) in diameter. All parts of it, but the bark in a greater degree, have a nauseous and acrid taste, and contain an unknown acrid principle, which appears to be freely soluble in alcohol, but slightly soluble in water.

Allied Plants.—Besides the different species of *Daphne* (see *MEZEREUM*), the following deserves to be briefly noticed as possessing similar virtues:

LAGETTA LINTEAREA, *Lamarck*, s. *Daphne Lagetta*, *Swartz*.—Lace tree.—A small tree of Jamaica and other West Indian islands, with small white, nearly sessile flowers, evergreen shining ovate-cordate leaves, and a brownish or ash-colored bark, the liber of which is readily separable into twenty or more transverse bast-layers having the appearance of delicate lace.

Medical Action and Uses.—The berries are emetic and poisonous. The fresh bark, applied to the skin, causes redness and vesication and sores which are very difficult to heal. When chewed it excites free salivation and causes pain and soreness of the mouth—qualities which have led to its being used as a masticatory in *toothache*. These qualities are very analogous to those of *mezezon*. The powdered bark is emetic and purgative, and a decoction of it is sudorific and expectorant. As an emetic it may be given in doses of 5 or 6 grains (Gm. 0.30–0.40).

DRACONTIUM.—DRACONTIUM.

Skunk-cabbage, *Skunk-weed*, *Polecat-weed*, E.; *Racine de pothos fétide*, Fr.; *Stinkende Drachenwurzel*, G.

The rhizome and roots of *Dracontium foetidum*, *Linne*, s. *Ictodes foetidus*, *Bigelow*, s. *Symplocarpus foetidus*, *Salisbury*, s. *Pothos foetida*, *Michaux*. *Meehan*, *Native Flowers*, i. pl. 15.

Nat. Ord.—Aracææ.

Origin.—This common North American perennial grows in bogs and moist grounds, and flowers in April and the early part of May. The spathe, which precedes the leaves, is hooded-shellform, pointed, rather fleshy, of a variegated purplish-brown and yellow color, and encloses a short oval spadix which is densely tessellated with fleshy flowers, and enlarges finally to a spongy mass superficially covering the globular seeds. The leaves are radical, $1\frac{1}{2}$ to 2 feet (45 to 60 Cm.) long, on short petioles, smooth, ovate, and heart-shaped. All parts have a very fetid odor, which on bruising is more decided.

Description.—The rhizome, which should be collected early in the spring, is tuberos, truncate above and below, 3 to 4 inches (7 to 10 Cm.) long and about 2 inches (5 Cm.) in diameter, of a gray-brown color, the upper half beset with numerous long fleshy rootlets, which in drying become much shrivelled and longitudinally wrinkled, and are of a lighter color and weaker taste than the rhizome. The latter is white internally, or gray when old, has the fibro-vascular bundles scattered, but rather crowded within the nucleus-sheath, and possesses a very acrid and biting taste, which is gradually lost when long kept.

Constituents.—The root was analyzed by J. M. Turner (1836), who did not succeed in isolating the acrid principle, which appears to be altered by heat, and who obtained from it a volatile fatty matter, a little volatile oil, resin, wax, fixed oil, sugar, gum, and starch.

Medical Action and Uses.—*Dracontium*, when chewed, produces irritation of

FIG. 103.

Dracontium foetidum: section through one-half of upper part of rhizome, natural size.

the mouth, and, applied to a freshly-blistered surface, augments its secretion. Internally, it occasions vertigo, nausea, and frequently vomiting. Its fetid smell probably suggested its employment as an anti-spasmodic, and reports are not wanting of its having cured *hysteria*, *chorea*, and spasmodic *asthma*, and even *chronic bronchitis*, *chronic rheumatism*, and *dropsy*. The dose is from 10 to 20 grains (Gm. 0.60–1.20) of the recently-dried root. An infusion made with an ounce (Gm. 32) of the dried root to a pint of water may be prescribed in doses of 1 or 2 tablespoonfuls. A saturated tincture made in the same manner may be given in the dose of 1 or 2 teaspoonfuls.

DROSERA.—SUNDEW.

FIG. 104.

Herba rostellæ.—*Rossolis*, *Rosée du soleil*, Fr.; *Sonnenhau*, G.

The entire plant, *Drosera rotundifolia*, Linné.

Nat. Ord.—*Droseraceæ*.

Description.—This little perennial is frequently met with in peat-bogs and near swamps in Europe and North America, particularly in the northern section of this continent. It has a tuft of petiolate radical leaves which are nearly orbicular, fleshy, and upon the upper surface covered with numerous whitish or, toward the margin, purplish glandular bristles. The scape is about 4 inches (10 Cm.) high, and bears a circinate one-sided raceme of small flowers with five white petals, five stamens, and three styles. The plant flowers in July and August, is inodorous, and has an acidulous, bitterish, and acrid taste. According to Vigier (1878), the plant loses on drying 85 per cent. of moisture, and when dry yields 25 per cent. of extract with 60 per cent. alcohol.

The nearly-allied *D. longifolia*, Linné, s. D. *intermedia*, Hayne, likewise a native of both continents, is chiefly distinguished by its spatulate-oblong leaves.

Constituents.—The juice of sundew was examined by Trommsdorff (1833), who found in it free malic acid, various salts, and a red coloring matter, which is precipitated by acetate of lead. Hager believed the acid to be a mixture of citric and malic acids. Lugan (1878) succeeded in crystallizing it, and regards it as peculiar; but G. Stein (1879) showed it to be citric acid. By treatment with chloroform, Lugan extracted a greenish-brown, odorous, and very acrid resin: the juice contains also glucose, and the viscous exudation of the glands has a neutral reaction, and does not contain formic and butyric acids, the presence of which was reported by Reiss and Will.

Drosera rotundifolia, natural size.

Medical Action and Uses.—Two species which have been used in medicine. *D. rotundifolia* and *D. longifolia*, appear to be identical in their qualities. In Europe for several centuries they had a popular reputation as remedies in chronic bronchitis and asthma, and externally the juice was applied to remove warts. In 1860 some attempts were made to revive the use of this medicine by employing its expressed juice, which, however, it was found, might be taken to the extent of 3 or 4 ounces daily without producing any distinct effects. Some cases of *bronchitis* were reported to be benefited by it, and in *whooping cough* it appeared sometimes to exert a palliative influence, particularly by lessening the tendency to vomit during the paroxysms. This effect has been very plausibly attributed to the preparation employed—viz. one made by macerating the plant in alcohol. Murrell, however, alleges that while 5-drop doses of a "one-in-ten tincture" aggravated the cough in a case which he treated, $\frac{1}{2}$ -drop doses palliated, and then arrested, the cough (*Lancet*, Apr. 17, 1880).

DUBOISIA.—DUBOISIA.

The leaves of two species of *Duboisia*, indigenous to Australia.

Nat. Ord.—*Solanaceæ*, *Salpiglossideæ*.

Description.—*DUBOISIA MYOPOROIDES*, R. Brown, is a tree-like shrub. Its leaves are alternate, short-stalked, smooth, 2 to 4 inches (5–10 Cm.) long, $\frac{1}{2}$ to 1 inch (12–25 Mm.) broad near the middle, lanceolate, entire and slightly revolute on the margin, narrowed toward the apex and base, inodorous and of a bitter taste. The prominent midrib

is marked on the upper side by a slight ridge. The flowers are whitish or lilac-colored, bell-shaped, and have four didynamous stamens with reniform anthers; the fruit is a small roundish black berry, resting with its lower half in the five-toothed, persistent calyx, and containing in each of the two cells two to four oblong-reniform and reticulate brown seeds.

DUBOISIA HOPWOODII, *P. von Müller*. This tree-like or shrubby plant is called *pituri* or *pedgery*; it is rare and its fruit is unknown. The leaves are short-petiolate, smooth, glossy, and rather thick, about 4 inches (10 Cm.) long, narrow and linear or somewhat lanceolate, narrowed at the base, and finely acuminate, with the end often bent.

Constituents.—Dub. myoporoides was examined by A. W. Gerrard and A. Petit (1878), who isolated the alkaloid *duboisine* as a yellow viscous mass, which is colored red by sulphuric acid, and on warming the mixture gives off an unpleasant odor, suggestive of butyric acid. Duquesnel subsequently obtained the alkaloid in crystals, and Ladenburg (1880) proved it to be identical with hyoscyamine, and that the commercial duboisine sulphate, which is brown, amorphous, and hygroscopic, is identical with hyoscyamine sulphate, but contaminated with a resin-like body. A volatile alkaloid contained in these leaves is probably identical with *piturine*.

Pituri-leaves, examined by Mueller and Rummel, Petit (1879), Liversidge (1881), and others, were found to contain a volatile alkaloid, *piturine*, C_6H_7N , which when pure is a colorless liquid, but on exposure to light or air turns yellow and brown; it is very freely soluble in water, alcohol, and ether, has a nicotine-like odor, which changes to pyridine-like, and has an acrid and persistent pungent taste; its salts are bitter, mostly amorphous or with difficulty crystallizable, and readily part with a portion of the alkaloid. Sulphuric acid and potassium bichromate cause an orange color, changing to brown and green.

Physiological Action.—*On Animals:* The continued use of duboisine excites tetanus in frogs, and antagonizes the paralyzing action of muscarin on the heart. In these animals it seems to be far less operative than atropine (Ringer). $\frac{1}{2}$ grain of sulphate of duboisine subcutaneously administered to a dog lowered the respiration-rate from 20 to 12, and quickened the pulse-rate from 92 to 240 and upward. The animal staggered in walking and voided feces and urine, and was "evidently delirious," "moving as hunting-dogs do when lying before a fire dreaming." The pupils were widely dilated. Administered to a pigeon, it neither dilated the pupils nor in any other way affected the bird (Norris). Gibson concluded from his experiments: "1. That duboisine in quantities not exceeding Gm. 0.005 (gr. $\frac{1}{120}$) raises the arterial pressure without materially affecting the pulse-rate. 2. In doses not exceeding Gm. 0.05 (gr. $\frac{1}{4}$) it diminishes the blood-pressure and lessens the pulse-rate. 3. Gm. 0.05 (gr. $\frac{1}{4}$) and upward causes death, with the heart in diastole. 4. In larger doses than Gm. 0.05 (gr. $\frac{1}{4}$) it arrests the heart in diastole." It also in small doses contracts the arterioles, and in large doses dilates them (*Lancet*, Nov. 5, 1881).

On Man: The first experiments made with the extract and the sulphate of duboisine showed them to be powerful mydriatics, dilating the pupil more promptly and energetically than atropine, and sustaining this influence for a longer time. In its action on the eye duboisine differs from atropine in this, that it rapidly produces dilatation of the pupil and almost simultaneously total paralysis of accommodation, while repeated applications of atropine are necessary to paralyze the ciliary muscle completely. These differences are made apparent by applying the two agents to different eyes of the same person simultaneously. It is said that duboisine is much less apt than atropine to occasion irritation of the conjunctiva (Wecker). The statements of its action on the iris are not uniform. According to Wecker, a $\frac{1}{2}$ per cent. solution dilated the pupil in 20 minutes, and maintained it in that state for 7 days; while Risley found that the duration of its action is less than one-half of that of atropine sulphate, although a 2-grain solution of duboisine sulphate more rapidly paralyzes the ciliary muscle than a 4-grain solution of atropine sulphate (*Amer. Jour. of Med. Sci.*, Apr. 1880, p. 410). $\frac{1}{2}$ Mg. (gr. $\frac{1}{128}$), injected hypodermically, causes some dryness of the throat and indistinctness of vision; 1 Mg. (gr. $\frac{1}{64}$) quickens the pulse, flushes the skin or produces a patchy erythematous redness of it, and impairs the muscular power—an effect which distinguishes it from atropine. It differs further from atropine in lowering the pulse-rate, and, instead of stimulating the brain, it causes a sort of placid indifference or inertness, and even faintness, but, unless in large doses, no drowsiness. It dries the skin sweating under the influence of pilocarpine. In one case (Norris) an exceedingly minute piece of sulphate of duboisine was applied to the conjunctiva, where it melted. A few minutes afterward the patient became dizzy, her face was darkly flushed, and then she grew wildly delirious, was very restless, picked at surrounding objects, and had once or twice slight drawing up of her arms: she also persisted in her efforts to leave

the sofa on which she lay. These symptoms were allayed by a hypodermic injection of morphine. In a case reported by Holmes (*Phila. Med. Times*, xi. 189) about $\frac{1}{4}$ grain of duboisine was taken by mistake. In 10 minutes it occasioned dryness of the throat, and in half an hour numbness of the legs and arms; there was no delirium, but the patient became unconscious, and remained so for about 6 hours, breathing quietly; the face was not flushed, but the mouth was very dry and the temperature normal, and the pulse, which ranged to 108 or 112 before unconsciousness came on and so long as the patient was recumbent, fell to 80 when he sat up in bed. For several days the limbs remained weak and uncertain in their movements. Berner instilled into his own eye a solution of duboisine, and observed that "at the end of 10 minutes his sight became dull and objects appeared small and distant. The pupil was fully dilated, the accommodation suppressed, with photopsia and vertigo and a cold constriction of the temples. The face grew pale, the nose cold, and there was singing in the ears, with deafness. The mouth and throat were dry, and vomiting occurred. The respiration was frequent and superficial, the arms and legs were paretic, and limpid urine was copiously discharged. The paresis of accommodation lasted for 4 or 5 days, and the dilatation of the pupils from 5 to 6 days. The day after the experiment a slight sweating occurred, with physical and mental irritability and prostration" (*Times and Gazette*, Feb. 1881, p. 247). Heyl remarks: "That atropine instilled into the eye may excite an attack of acute inflammatory glaucoma is generally accepted by ophthalmologists as an established clinical fact" (*Amer. Jour. of Med. Sci.*, Apr. 1882, p. 398).

Duboisia Hopwoodii furnishes *pituri*, whose action differs from that of duboisine. According to Ringer, "it produces faintness, pallor, giddiness, tremor, hurried and superficial breathing, and increased frequency of the pulse, with perspiration; in large doses salivation, drowsiness, convulsive twitching, spasmodic rigidity of the extremities. In small doses, internally, it contracts, and in large doses widely dilates, the pupils; locally applied, it contracts, and then widely dilates, the pupils." It seems to be a feeble mydriatic (*Amer. Jour. of Med. Sci.*, Apr. 1879, p. 539).

Uses.—Duboisine may be used as a substitute for atropine in all *affections of the eye* for which the latter is employed, including disorders of *accommodation*, *iritis*, and diseases of the *cornea*. "The greater rapidity with which the dilatation of the pupil, and the paralysis of accommodation caused by it, pass off renders it superior to atropine for use in determining the refraction; while, on the other hand, its greater tendency to produce constitutional disturbance should cause it to be carefully used" (Norris). According to Little, the only superiority of duboisine over atropine consists "in gaining time in the study of refraction" (*Phila. Med. Times*, x. 321). It appears to have the same effect as atropine in moderating the *sweats* of phthisis, and the additional merit of reducing instead of accelerating the pulse. Dujardin-Beaumetz, Desnos, and others have used this preparation in the treatment of *exophthalmic goitre*, causing a marked diminution of the cardiac palpitation and vascular throbbing. It does not, however, lessen the tumor nor permanently suspend the symptoms of the disease (*Bull. de therap.*, xcix. 89; c. 59).

Duboisine may be given hypodermically in the dose of $\frac{1}{16}$ to $\frac{1}{80}$ grain (Gm. 0.0005 to 0.001), and for ophthalmological purposes a solution is used of 3 or 4 grains (Gm. 0.20–0.25) in a fluidounce (Gm. 32) of distilled water.

DULCAMARA, U. S., Br.—DULCAMARA.

Stipites dulcamaræ.—Bittersweet, Woody nightshade, E.; *Tiges de douce-amère* (*de morelle grim-pante*), Fr.; *Bittersüss-Stengel*, G.

The young branches of *Solanum Dulcamara*, *Linne* (s. *Dulcamara flexuosa*, *Moench*). Woodville, *Med. Bot.*, plate 33; Bentley and Trimen, *Med. Plants*, 190.

Nat. Ord.—Solanaceæ, Solanææ.

Origin.—The bittersweet is a somewhat shrubby and climbing plant which grows throughout the greater part of Europe, in Northern Africa, and from Asia Minor east to North-western India and to China. It is naturalized in North America, and in many places is abundant. It grows around dwellings and in hedges and thickets on moist banks. The stem, when supported by shrubs, is sometimes 15 to 20 feet (4.5 to 6 M.) long, woody at the base, and divided into many flexuose branches dying back during the winter; the leaves are alternate, petiolate, and slightly pubescent beneath, the lower ones ovate with a heart-shaped base, the upper ones halberd-shaped or with two ear-like lobes at the base; the flowers are in small cymes, and have a deeply five-lobed, purple, sometimes whitish, corolla. The berries are oval, bright-red, and contain many minutely-pitted seeds.

Description.—The branches which are 1 or 2 years old are collected in the autumn after having shed their leaves, or in the spring before the leaves appear. They are $\frac{1}{4}$ inch (6 Mm.) and less thick, cylindrical or somewhat angular, longitudinally striate or furrowed,

FIG. 105.

Solanum Dulcamara, Linné.

and more or less warty. The corky layer is pale greenish- or yellowish-brown, separates easily, and covers a dark-green bark, which is lighter-green in the bast-layer; and this consists of thin-walled parenchyma, containing in the inner layer minute crystals of calcium oxalate, and in the outer zone a circle of tough bast-fibres, either single or in small groups. The greenish (afterward yellowish) wood is porous, striate by the fine medullary rays, and consists of one or two annual rings; the whitish pith has been usually absorbed. The odor is unpleasant, somewhat narcotic, weak in the dried

FIG. 106.

Transverse section of branch.

stalks; the taste is bitter, afterward sweet. Bittersweet is generally met with in the market cut into short sections.

Constituents.—The bittersweet principle has been variously named *picroglycion*, *dulcarin*, and *dulcamarin*. Desfosses (1821) separated from the drug *solanine*, an alkaloid previously discovered by him in *Solanum nigrum*, and he, as well as Pelletier, regarded the *picroglycion* as *solanine* mixed with glucose. Winckler (1841), Moitessier (1856), and others considered the alkaloid of *dulcamara* as distinct from the *solanine* of potatoes; but since the discovery of the glucoside nature of *solanine* in 1859 the supposed *solanine* from bittersweet does not appear to have been again examined.

Wittstein (1852) isolated from bittersweet *dulcamarine*, an alkaloid having a resinous appearance and the odor and taste of the plant. E. Geissler (1875) obtained this product, but recognized it as a mixture. He obtained *dulcamarin*, $C_{22}H_{34}O_{10}$, by digesting the aqueous infusion of bittersweet with granular animal charcoal, washing the latter, and exhausting it with boiling alcohol, evaporating, dissolving in water, precipitating with ammonia, and the filtrate therefrom with subacetate of lead, digesting the washed precipitate with alcohol, and decomposing it with sulphuretted hydrogen. It forms a yellowish powder of a strongly bitter and then sweet taste, is soluble in alcohol and water, insoluble in ether, chloroform, benzol, carbon bisulphide, and petroleum benzin, and is decomposed by diluted acids into sugar and brown, tasteless *dulcamaretin*.

The other constituents, gummy, resinous, and waxy matters, are not of medicinal importance.

Admixtures.—The cut stems of *Humulus Lupulus*, Linné, and *Lonicera Periclymenum*, Linné, are said to be occasionally mixed with *dulcamara* in Europe; they have none of the characteristics of the latter.

Off. Prep.—Extr. *dulcamaræ* fluid., U. S.; Infusum *dulcamaræ*, Br.

Physiological Action.—*On Animals:* The extract, introduced into the stomach of rabbits, occasions a remarkable degree of apathy, but not true sleep, with great flaccidity of the muscles, but no paralysis. The sensibility to pain as well as to contact is blunted; the pulse- and respiration-rates are reduced; the temperature is raised; the pupils are not altered; the ears and the lips become cyanosed; the head is bowed downward, and moves laterally to and fro; and death takes place in convulsions. The stomach presents an intensely dark-red color from the congestion of its blood-vessels, while the intestinal mucous membrane is pale. The large veins of the thorax and abdomen are distended with dark blood.

On Man: In large doses *dulcamara* is stated by some reporters to cause dryness, heat, and constriction and stinging in the throat, thirst, and sometimes diarrhoea. Feeble persons, it is said, are apt to experience twitching of the eyelids and lips, with tremulousness

of the limbs; the head is heavy and giddy, and, as in the lower animals, a cyanotic hue of the face and hands may be observed, and sometimes an erythematous eruption of the skin, with a tendency to diaphoresis. The action of dulcamara upon the human heart is not definitely determined, but it probably renders the circulation slower and more languid. Dulcamara, it has been alleged, produces itching and heat in the female organs of generation, with painful strangury, and sometimes even venereal desires; while, on the other hand, to it has been attributed a power of subduing the morbidly-active sexual appetite. It is proper to state that Dr. John Harley experimented upon man with the expressed juice, and also with the tincture, in small and large doses, without any appreciable physiological effect.

Medical Uses.—The so-called scientific therapeutists of the present day are disposed to deny any curative virtues to dulcamara, because they are unable to explain those it is alleged to possess according to their notions of its mode of action. Such a reason may, in a logical sense, be called impertinent. The claims of dulcamara rest on the same grounds as those of opium, mercury, and cinchona—the ground of clinical experience. It was long used as a popular remedy, and subsequently by physicians, for *cutaneous eruptions*, both internally and externally, and especially for psoriasis and other scaly diseases of the skin, and also for acne, impetigo, chronic eczema, and ecthyma. It is said to be most apt to cure those diseases when they occur in persons of a strumous habit. It has had considerable repute as a remedy for chronic muscular *rheumatism*, and also in chronic *bronchitis*, *whooping cough*, and other chronic pulmonary affections in which cough is a prominent symptom. An antaphrodisiac property was ascribed to dulcamara by Dr. W. P. Dewees, who observed that a patient who was taking it for a disease of the skin lost his venereal desire. On discontinuing the use of the medicine the patient's normal function was restored, but on resuming its use again the original effect was repeated. In five cases in which Dr. Thomas Harris employed it the venereal appetite was suspended during its use. Dr. Dewees prescribed it successfully in cases of *nymphomania* and *satyriasis* (*Amer. Cyclopædia of Med. and Surg.*, ii. 23).

Dulcamara is best used in decoction, which is made from the fresh young branches (3i to q. s. of water reduced by boiling for 15 minutes, then adding water to make a pint). The infusion and the fluid extract may also be employed. It must be long continued to produce its curative effects.

ECBALII FRUCTUS, Br.—SQUIRTING-CUCUMBER FRUIT.

Cucumis asininus, *Cucumis agrestis*.—Wild cucumber, E.; *Concombre sauvage* (*purgatif*, *d'âne*), Fr.; *Springgurke*, *Esels-Kürbis*, *Spritzgurke*, G.

The fruit of the squirting cucumber, *Ecballium* (*Momordica*, *Linne*) *Elaterium*, A. *Richard*, s. *Ech. officinale*, *Nees*, s. *Ech. agreste*, *Reichenbach*, s. *Elaterium cordifolium*, *Moench*. *Step. and Church*, *Med. Bot.*, plate 34; *Bentley and Trimen*, *Med. Plants*, 115.

Nat. Ord.—Cucurbitaceæ.

Origin.—The plant is a common weed in dry and waste places in Southern Europe, and eastward thence to Persia. It has a perennial, fleshy, white root, a trailing, succulent, bristly stem 2 to 4 feet (0.6 to 1.2 M.) long, alternate, bristly, bluntly-triangular, and cordate leaves, and unisexual monœcious flowers with deeply five-lobed, yellow, and veined corollas. The plant is cultivated to a small extent for medicinal purposes in Germany, France, and at Mitcham and Hitchin in England, the seeds being sown about March, the seedlings planted out in June, and the nearly ripe fruit collected in August or early in September.

Description.—The fruit is nodding from the recurved stalk, 2 inches (5 Cm.) or less in length, about 1 inch (25 Mm.) thick, oblong, and somewhat tapering above, pale-green, beset with fleshy prickles, three-celled, and contains a bitter watery, mucilaginous juice in which the numerous oblong, compressed, polished, light-brown seeds are immersed. When mature the fruit becomes yellowish, and separates suddenly from the stalk, at the same time violently expelling the juice and seeds from the orifice formed at the base. The fruit is collected with the stalk when almost ripe for preparing elaterium.

ELATERIUM, Br.—Elaterium, *E. Fr.*, G. The following process is given for its preparation: Take of Squirting-Cucumber fruit, very nearly ripe, 1 pound. Cut the fruit lengthwise and lightly press out the juice. Strain it through a hair-sieve and set it aside to deposit. Carefully pour off the supernatant liquor, pour the sediment on a linen filter, and dry it on porous tiles with a gentle heat. The decanted fluid may deposit a second portion of sediment, which can be dried in the same way.—*Br.*

This is essentially the process recommended by Dr. Clutterbuck (1820), except that he directs the surface of the fruit to be moistened with cold water, thus preventing the juice from adhering, and the split fruit to be rinsed in cold water for recovering the juice adhering to the inside. With an increased pressure a larger amount of juice and of deposit is obtained, but the latter is then of inferior quality. The deposited elaterium may be dried with a very moderate heat, but exposure to the sunshine should be avoided. Clutterbuck obtained only 6 grains of elaterium from forty specimens of squirting cucumber; with slight pressure 40 pounds of the fruit will generally yield $\frac{1}{2}$ ounce, and in warm, dry seasons even $\frac{3}{4}$ ounce, of elaterium.

Elaterium is in light, friable, flat, or slightly incurved, cake-like fragments, frequently marked on their surfaces with the impression of the linen or paper on which they were dried. When fresh it has a pale-green color, changing by age to gray, and then often containing minute sparkling crystals on the surface. It breaks with a fine granular fracture, and has a slight tea-like odor and an acrid and bitter taste. It does not effervesce with acids; a cooled decoction of it is not colored blue or is but slightly tinged by solution of iodine, showing the nearly complete absence of starch. It yields half its weight to boiling rectified spirit; and this solution, on being concentrated and added to warm solution of potassa, deposits on cooling not less than 20 per cent. of elaterin in colorless crystals.—*Br.*

Constituents.—The analyses of Braconnot, Paris, Marquart, Landerer, and Koehler indicate the presence in the fruit of resin, pectin, and albuminous and gummy matters, but besides *elaterin* no compound of importance. (See ELATERINUM.) According to Koehler (1869), the juice contains only 3.5 per cent. of organic and 1.5 per cent. of inorganic constituents.

Walz (1859) obtained from the entire plant collected with the root the following principles, which are stated to be present likewise in elaterium:

Prophetin, also found in the fruit of *Cucumis prophetarum*, *Linné*, a yellowish powder, slightly soluble in water, more in alcohol, freely in ether; precipitated by tannin; is a glucoside; *ecbalin* or *elateric acid*, resin-like, bitter, and acrid, soluble in alkalies, alcohol, ether, and in 20 parts of water; *hydro-elaterin*, amorphous, soluble in water, alcohol, ether, and alkalies; is not a glucoside; *elaterid*, very bitter, insoluble in water and ether, soluble in alcohol and alkalies, also in concentrated acids.

ELATERINUM, U. S.—ELATERIN.

Elatérine, *Elatine*, Fr.; *Elaterin*, G.

Formula $C_{20}H_{28}O_5$. Molecular weight 348.

Preparation.—Elaterin is a neutral principle prepared from elaterium, and discovered by Hennell and by J. D. Morris (1831). The latter prepared it by evaporating the tincture of elaterium to an oily consistence, and, while still warm, pouring it into a warm solution of potassa; in place of which he afterward recommended boiling water. The chlorophyll adhering to the crystals was recommended by Marquart (1833) to be removed by careful washing with ether, or by Power (1875) preferably by agitating the alcoholic solution with benzin. It is not unlikely, however, that in this way a portion of the principle may be lost, for Buchheim (1872) observed that on adding potassa to a hot alcoholic solution of elaterin a compound soluble in water is formed. According to him, elaterin is the anhydride of elateric acid, and converted into the latter by heat alone; hence the importance of avoiding heat in the preparation of elaterium. The best method of obtaining elaterin is to exhaust elaterium with chloroform, from which solution white crystals will be immediately deposited on the addition of ether; after washing with a little ether and recrystallizing from chloroform pure elaterin will be obtained (*Pharmacographia*). The yield varies to some extent; Morris (1831) obtained between 15 and

FIG. 107.

Ecbalium officinarum, Richard.

26 per cent.; Flückiger and Hanbury (1874), 27.6 and 33.6; Walz (1859), even 50 per cent. It was observed by Marquart (1833), Walz (1859), and Köhler (1869) that the amount of elaterin diminishes very considerably in the fruit as the season advances.

Properties.—Elaterin is in colorless, shining, hexagonal scales or prisms, which are not altered on exposure, are inodorous, and have a somewhat acrid and extremely bitter taste. They have a neutral reaction to test-paper, are insoluble in water and petroleum benzin, and require for solution in the cold over 120 parts of alcohol (Golding Bird, 1840), 290 parts of ether (Hennell), and 2 parts of boiling alcohol. Elaterin is likewise soluble in amylie alcohol, carbon bisulphide, chloroform, hot olive oil, and oil of turpentine. The effect of potassa has been referred to above; the acid body thereby produced is inert, since 1.0 Gm. of it produced no effect. Elaterin is not a glucoside, and its solutions are not precipitated by tannin. When heated to 200° C. (392° F.) it turns yellow and melts to a transparent liquid, which on cooling congeals to an amorphous mass; at a higher heat it gives off white somewhat acrid vapors, and burns with a sooty flame, leaving no residue (Zwenger, 1843). According to Power (1875), elaterin is not changed by chlorinated alkalis. Nitric acid produces, after several hours, a pinkish tinge, but when heated at once a red coloration. Sulphuric acid dissolves it with a deep-red color, the solution yielding a brown precipitate with water; the color of the solution gradually changes to deep-brown, and ultimately to light-green, on the addition of a fragment of potassium bichromate. Lindo (1878) observed that the addition to elaterin of a few drops of melted carbolic acid, followed by sulphuric acid, produces a magnificent crimson color, changing to orange and scarlet.

Off. Prep.—Trituratis elaterini, *U. S.*

Physiological Action.—Elaterium, however it may be given to dogs and rabbits, does not vomit or purge them, but destroys them with tetanoid phenomena. In some other animals the subcutaneous use of elaterium produces profound and fatal exhaustion. In man its internal use causes more or less vomiting, severe griping, and profuse watery stools, with a sense of great debility.

Medical Uses.—Elaterium is used as a purgative in those cases only in which a drastic operation, with profuse serous discharges, is desired. Hence it may be prescribed with great effect to relieve the brain or the lungs threatened with the dangers of *congestion*, provided no contraindication exists in the patient's debility or in diseases of the digestive canal. It was one of the most renowned of the ancient remedies for *dropsy*, and in recent times it has shown its power by evacuating serous collections which other purgatives and all diuretics failed to remove. It is, however, most frequently used in abdominal dropsy.

The variable strength of elaterium suggests caution in its use. $\frac{1}{16}$ grain (Gm. 0.004) may be given in a pill made with extract of hyoscyamus or confection of roses, and repeated every hour until the effects begin to appear. Elaterin is more active in alcoholic solution, or it may be given in the officinal (1882) trituration of elaterin. The *dose* is from $\frac{1}{80}$ gr. to $\frac{1}{12}$ gr. (Gm. 0.002–0.005).

ELEM, Br.—ELEM.

Resina (s. Gummi) Elemi.—*Elémi*, *Resine élémi*, Fr.; *Elemi*, G.

A concrete resinous exudation, the botanical source of which is undetermined, but is probably *Canarium commune*, *Linneé* (*Rumph. Amb.*, vol. ii. plate 47). Chiefly imported from Manila. *Br.* Bentley and Trimen, *Med. Plants*, 61.

Nat. Ord.—Burseraceæ.

Origin.—The name of elemi has been given to various resinous products which have from time to time appeared in commerce, and which, it is believed, are all derived from trees of the *Nat. Ord.* Burseraceæ. The British Pharmacopœia refers Manila elemi, a product of the Philippine Islands, to the species named above, a tall tree indigenous to the Moluccas and to other parts of tropical Asia, while Blanco (1845) states that it is obtained from *Leica abilo*, a tree scarcely known. Perrottet (1821) sent specimens of the elemi tree to Paris and to Senegambia, and stated (1823) that the tree is scarified twice a year, and the flow of the oleoresin promoted by kindling a fire near the tree. Baup (1851) believed *Canarium olbum*, *Rænschel*, to be Perrottet's tree (Flückiger, *Pharmacognosie*).

Description.—Manila elemi is in soft, granular, transparent masses when fresh, but is generally met with in the shops in solid pieces, which are externally pale lemon-yellow and clear, internally opaque, nearly white, and mixed with chips and other impurities.

It breaks with a dull granular fracture and readily fuses to a transparent liquid. Moistened with alcohol, it disintegrates and shows a large number of small acicular crystals. It has a strong aromatic somewhat terebinthinate odor and a warm, aromatic, and acrid taste.

Constituents.—Flückiger and Hanbury (*Pharmacographia*) obtained from the drug 10 per cent. of a colorless, neutral, fragrant, and strongly dextrogyre volatile oil. An oil of elemi obtained by H. St. Claire-Deville (1849) had a strong rotatory power to the left and the composition $C_{10}H_{16}$.

On treating elemi with alcohol, Maujean (1823) obtained a soluble amorphous resin, which Baup (1851) named *brein*, and succeeded in crystallizing by the very slow evaporation of its alcoholic solution. Maujean's insoluble resin was by Bonastre (1824) crystallized from its solution in boiling strong alcohol; it is Baup's *amyrin*, and, like brein, is readily soluble in ether and insoluble in water. The same author obtained also *bryoidin* and *breidin*, both fusible, the former having a bitter and acrid taste; it is easily soluble in alcohol, ether, and volatile and fixed oils, slightly soluble in cold water, but crystallizes from boiling water, from alkaline solutions, or from dilute acetic acid in silky threads or in moss-like masses. *Breidin* is likewise crystalline, readily soluble in alcohol, less in water or ether. E. Buri (1876) gives to amyrim the formula $(C_5H_8)_5 \cdot 2H_2O$. He found it to be soluble in ether, chloroform, and carbon bisulphide, to be fusible at 177° C. (350.6° F.), and to sublime when carefully heated in thin layers. The mother-liquors of amyrim yielded him (1878) *elemic acid*, $(C_5H_8)_7O_4$, the potassium salt of which crystallizes from its strong alkaline solution in needles.

Varieties.—The following resinous products are sometimes met with as distinct varieties of elemi:

MAURITIUS ELEMI, obtained from *Colophonia mauritiana*, Commerson, a large tree of Mauritius; it is at first liquid, and resembles the Manila elemi.

MEXICAN ELEMI, supposed to be obtained from *Amyris elemifera*, Royle, is in light- or dark-yellow somewhat greenish masses, of a waxy lustre, translucent or opaque, friable, but readily softening in the mouth.

BRAZILIAN ELEMI, collected from *Icica Icicariba*, De Candelolle, and other species of the same genus; it forms soft yellowish-white or solid pale or greenish-yellow masses.

All these varieties have a similar though not identical odor, and disintegrate when treated with cold alcohol, with the separation of small crystals, which are probably identical with *amyrim*.

The *decamalee resin* of India, which resembles elemi, is the exudation of *Gardenia gummifera*, Linné, and *G. lucida*, Roxburgh, Nat. Ord. Rubiaceæ.

Off. Prep.—Unguentum elemi, Br.

Medical Action and Uses.—The qualities of elemi are analogous to those of the turpentine, and it might probably be used for the same purposes internally. It is, however, only employed as an external application, in plaster or ointment, as a dressing for blisters, issues, indolent ulcers, etc. In this country it is rarely prescribed. Oil of elemi is analogous in its action to oil of turpentine.

ELIXIR AURANTII, U. S.—ELIXIR OF ORANGE.

Elixir simplex.—Simple elixir, E.; *Elixir simple*, Fr.; *Einfaches Elixir*, G.

Preparation.—Oil of Orange 1 part (100 grains or 6.5 Gm.); Cotton 2 parts (200 grains or 13 Gm.); Sugar, in coarse powder, 100 parts (10,000 grains = 23 oz. av. or 650 Gm.); Alcohol, Water, each a sufficient quantity; to make 300 parts (30,000 grains or 69 oz. av., about 60 fluidounces.) Mix alcohol and water in the proportion of 1 part of alcohol to 3 parts of water (alcohol 20 to water 49 fluidounces). Add the oil of orange to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack tightly in a conical percolator, and gradually pour on the mixture of alcohol and water until 200 parts (20,000 grains = 46 oz. av. = 45 fluidounces, or 1300 Gm.) of filtered liquid are obtained. In this liquid dissolve the sugar by agitation, without heat, and strain.—U. S.

(For remarks on the solution of volatile oils in aqueous liquids see *AQUÆ MEDICATÆ*, page 232.) The elixir aurantii, U. S. P., should not be confounded with the elixir aurant. comp., P. G. (for formula of which see page 289).

ELIXIRIA (Elixirs, E., Fr.; Elixire, G.), in the sense in which this name was formerly, and is still to a certain extent, applied on the continent of Europe, are certain compound tinctures, spirits, and wines, many of which have an unpleasant taste. In modern American pharmacy the name has been adopted for sweetened and aromatized alcoholic preparations or *cordials* containing often minute quantities of the medicinally active ingredients.

which are added in the form of tincture or of fluid extract or as a solution of the saline ingredient, so that a tablespoonful or wineglassful of the elixir will represent only a very moderate or even minute dose of the active drug. (For a full account of this class of preparations, with formulas for about 250 varieties, consult *Elixirs, their History, etc.*, by J. C. Lloyd, 1883.) The elixirs adopted by the American Pharmaceutical Association (1873, 1875) have for their base either the simple (uncolored) or the red elixir; a teaspoonful or a tablespoonful represents a medicinal dose. The formulas here given will serve as types for preparing others, and, if desired, the flavor may be varied by the substitution of other volatile oils for the oil of orange:

COMPOUND TINCTURE OF COCHINEAL. Macerate for a day 120 grains compound powder of cochineal (composed of 48 grains of potassium bitartrate and 24 grains each of powdered cochineal, alum, and potassium carbonate) in 2 fluidounces of diluted alcohol, and filter.

RED ELIXIR. Mix simple elixir $15\frac{1}{2}$ fluidounces with compound tincture of cochineal $\frac{1}{2}$ fluidounce.

ELIXIR OF CALISAYA. Mix 3 fluidounces of tincture of cinchona with 13 fluidounces of simple elixir.

COMPOUND ELIXIR OF CINCHONA. Mix compound tincture of cinchona 3 fluidounces with simple elixir 13 fluidounces.

ELIXIR OF QUININE, CINCHONINE, AND IRON (incorrectly called *elixir of cinchona and iron*). Dissolve 256 grains of ammonio-citrate of iron and 12 grains each of the sulphates of quinine and cinchonine in $\frac{1}{2}$ fluidounce of water, and mix with $15\frac{1}{2}$ fluidounces of simple elixir.

ELIXIR OF QUININE, CINCHONINE, IRON, AND BISMUTH. Dissolve 256 grains of ammonio-citrate of bismuth in 1 fluidounce of water, and mix with 15 fluidounces of the elixir of quinine, cinchonine, and iron.

ELIXIR OF QUININE, CINCHONINE, IRON, AND STRYCHNINE. Dissolve $2\frac{1}{2}$ grains of strychnine with 5 grains of citric acid in 16 fluidounces of the elixir of quinine, cinchonine, and iron.

ELIXIR OF PYROPHOSPHATE OF IRON, QUININE, AND STRYCHNINE. Dissolve 256 grains of pyrophosphate of iron in 4 fluidounces of distilled water, and add 6 fluidounces of syrup and a solution of $2\frac{1}{2}$ grains of strychnine and 128 grains of quinine in $5\frac{1}{2}$ fluidounces of alcohol and $\frac{1}{2}$ fluidounce of spirit of orange.

ELIXIR OF HOPS. Mix tincture of hops 8 fluidounces, spirit of orange 2 fluidrachms, spirit of cinnamon 10 minims, syrup 6 fluidounces, and water 2 fluidounces.

ELIXIR OF GENTIAN WITH IRON. Mix fluid extract of gentian $\frac{1}{2}$ fluidounce, diluted alcohol $7\frac{1}{2}$ fluidounces, spirit of orange 2 fluidrachms, spirit of cinnamon 10 minims, syrup 6 fluidounces, and 256 grains of ammonio-citrate of iron previously dissolved in 2 fluidounces of water.

ELIXIR OF GUARANA. Percolate 4 troyounces of powdered guarana with diluted alcohol until 8 fluidounces of tincture have been obtained; then add spirit of orange 2 fluidrachms, spirit of cinnamon 10 minims, syrup 6 fluidounces, and water 2 fluidounces.

ELIXIR OF VALERIANATE OF AMMONIUM. Dissolve 256 grains of crystallized ammonium valerianate with the aid of a few drops of ammonia-water in 16 fluidounces of red elixir.

ELIXIR OF VALERIANATE OF AMMONIUM AND QUININE. Dissolve in 16 fluidounces of the preceding elixir 128 grains of valerianate of quinine.

ELIXIR OF BROMIDE OF POTASSIUM. Dissolve 1280 grains of potassium bromide in 16 fluidounces of red elixir.

ELIXIR OF PYROPHOSPHATE OF IRON. A mixture of 256 grains of pyrophosphate of iron, dissolved in 1 fluidounce of water, and 15 fluidounces of simple elixir.

ELIXIR OF CITRATE OF BISMUTH. Dissolve 256 grains of citrate of bismuth in 4 fluidounces of water, adding a few drops of ammonia, and mix with 12 fluidounces of simple elixir.

EMPLASTRA.—PLASTERS.

Emplâtres, Fr.; *Plaster*, G.

Plasters are solid tenacious preparations intended for external use, considerably harder than cerates, so that they cannot be spread at the ordinary temperature, yet of such a composition that they will be pliable and adhesive at the temperature of the body.

According to their composition they are distinguished into two classes—namely, *plasters* properly so called (*stéarates* of the French), the base of which consists of a fusible and insoluble lead soap; and *resinous plasters*, which owe their adhesiveness to a resin mixed with some wax or fat, and for this reason are called *ointment-plasters* (*onguents-emplâtres* by the French); they are the *rétiuolés solides*, or hard resin-fats, of Guibourt.

The *preparation* of all plasters containing more than one ingredient is effected in a manner similar to that of the cerates, with such modifications as are necessitated by their greater firmness and higher fusing-point. The simple plaster or the resin is first liquefied, care being taken to avoid too high a heat; the wax, fat, or other fusible substances are then added, and lastly oleoresins and aromatic products which would be injured by long-continued heat, and gum-resins or other substances which are infusible and must be mechanically incorporated with the solidifying plaster. The latter may be accomplished in several ways, according to the nature of the substances to be added: they are either rubbed fine and to a perfectly smooth paste with some fat, volatile oil, or oleoresin, or they are finely powdered and passed through a sieve into the cooling plaster, which is then to be stirred until firm enough to prevent the mechanical admixtures from separating. If extracts are to be incorporated, they should, if possible, be prepared with strong alcohol, so as to be fusible with the other ingredients of the plaster. Most gum-resins are not completely fusible or readily pulverizable, and are therefore best converted into a smooth paste in the manner indicated above. The use of some petroleum benzin during the trituration will often be found advantageous for accomplishing the object in view.

Straining is best avoided in preparing plasters. Should it be found necessary, it is never to be deferred until the infusible ingredients have been added, but performed with the smallest possible bulk and with those portions of the material having the lowest fusing-point. On the whole, however, it will be found more advantageous and expeditious, more particularly for the extemporaneous preparation of plasters, to use only purified ingredients, so that straining may not be required.

For convenience in handling and dispensing plasters are rolled into cylinders of convenient thickness. A slab or thick board is suitable for the purpose. The melted plaster is allowed to cool until it is of a soft, pliable consistence, when a convenient quantity is transferred to the slab previously moistened with water, and then kneaded with the moistened hand and rolled out to the desired thickness; when larger quantities are thus to be rolled out a smooth and straight board will be convenient as a roller, with its ends supported by ledges, whereby uniform thickness is secured. Plasters which contain vegetable powders or other substances soluble in water are treated in the same manner, except that the water is replaced by olive or a similar bland and non-drying oil. The most convenient size of such rolls or sticks is, for dispensing purposes, about the thickness of a finger or even smaller. They keep well if they are wrapped in wax- or paraffin-paper. The soft plasters are sometimes poured into boxes or kept in square cakes, the latter being cast in tin or paper moulds, as described under CERATES (see page 411).

Plasters are usually spread upon white sheepskin; for particular purposes chamois-skin, linen, muslin, or even paper (see CHARTÆ, page 420), may be used. The leather is extended and fastened upon a smooth board, and the desired size and shape are marked upon it either by pasting strips of paper on it or using tin frames of the requisite size and shape. Sometimes an apparatus is used consisting of a block of hard wood with an even or somewhat convex surface, over which a sheet-iron frame is fitted, cut out to the dimensions and shape of the plaster to be spread, and covering sufficient leather to serve for a margin. For rectangular plasters it is convenient to have two L-shaped pieces of sheet tin, each side of which is graduated in inches, commencing from the angle; by bringing the angle of one diagonally opposite to that of the other piece a rectangular or square outline of any desired size may be formed. When the leather has been properly prepared, a sufficient quantity of the plaster is to be fused by a moderate heat and with frequent stirring to avoid burning, and while still liquid is poured upon the leather and spread by means of a warm stout pallet-knife, with sufficient pressure to obtain a smooth and even surface. Various plaster-spreaders, with long and short, straight and curved handles, have been constructed, the spreader generally being a solid square or triangular piece of iron, which, once heated, will remain warm for a sufficient length of time to soften such portions of the plaster as may become hard until the whole has been evenly spread. Sometimes the spreader or blade is made hollow, for the purpose of introducing boiling water or a heater to maintain the necessary temperature. But with some practice the pallet-knife will be found quite sufficient for the ordinary sizes of plaster. The consistence at which the fused mass should be poured upon the

leather is of importance; if it be too thin, it will partly pass through the material and stain the outer surface; if too thick, it will congeal before it can be spread out, and require reheating by means of the plaster iron, and is then apt to become too fluid. For true plasters a temperature of 50° to 55° C. (120° to 130° F.) will be found to give the proper consistence; resinous plasters containing wax or fats should be cooled to a still lower degree. So-called *porous plasters* have been used for some years past. To perforate spread plasters extemporaneously, Prof. Remington (1878) devised a tool consisting of a brass wheel $\frac{1}{4}$ inch wide, and studded with sixteen punches in two alternating rows $\frac{1}{2}$ inch apart. The wheel revolves around a steel axle, which is connected with a handle 9 inches long, by means of which the requisite pressure is obtained.

The amount of plaster necessary for spreading a given area will depend partly upon the nature of the plaster and partly upon the thickness to which it is spread; on an average, 10 grains will be found sufficient for 1 square inch of surface. To prevent the clothes from becoming soiled, and to facilitate the removal of the plaster, a margin of about $\frac{1}{4}$ inch is left around the spread surface.

In European pharmacy the term *sparadrap* is used to designate plasters which, like adhesive, court, and similar plasters, consist of adhesive substances thinly spread upon certain kinds of muslin, silk, or paper. They are prepared in various ways, according to the nature of the adhesive material; two of these, capsicum plaster and court plaster, have now been admitted into the U. S. P. True plasters, to be made into sparadraps, require an apparatus generally consisting of a smooth board, upon which rests in an upright position a kind of trough into which the melted plaster is put; the trough is provided below with a slit through which the plaster escapes; the cambric or other material is guided by rulers while being drawn underneath the trough, which must be kept sufficiently warm to prevent the plaster from becoming too firm, and should be so constructed as to act not merely as a scraper, but likewise to press upon the material beneath sufficiently for spreading the plaster thinly but evenly. Paper sparadraps are made in the same manner. (See also CHARTA, page 421.) (For a figure and description of an apparatus suitable for the purpose see *Amer. Jour. Pharmacy*, 1869, p. 455.)

When kept for a long time plasters are apt to become brittle. With rolled plasters the cause may be found partly in the removal of the glycerin. If not otherwise injured, they may be usually restored by fusing them carefully over a little water and incorporating with the melted mass $\frac{1}{2}$ to 1 per cent. of olive oil. To restore the adhesiveness of spread plasters is often a difficult matter, and must in all cases depend upon the nature of the plaster. Heating the surface of the plaster until it becomes soft, covering the softened surface with a solution of turpentine or Canada balsam, and then laying aside the plaster for a day, will usually accomplish the object. For some years past certain manufacturers have used caoutchouc to keep plasters pliable and adhesive. This can be successfully made, according to J. W. Worthington (1871), by macerating 1 ounce of finely-cut caoutchouc in a pint of petroleum benzin until a thick solution is obtained, of which 1 part is added to 7 or 8 parts of melted plaster. Chicle is likewise used for this purpose, and is incorporated by melting it with the plaster. (See GUTTA-PERCHA.)

If non-resinous extracts and fixed or volatile oils are ordered in such quantities as to interfere with the adhesive properties of the plaster, Shael (1873) recommends them to be incorporated with powdered tragacanth. This mixture is spread upon adhesive plaster, of which a sufficient margin is left uncovered.

EMPLASTRUM AMMONIACI, U. S.—AMMONIAC PLASTER.

Emplâtre de gomme ammoniacque, Emplâtre fondant (résolutif), Fr.: *Ammoniak-Pflaster*, G.

Preparation.—Ammoniac 100 parts ($5\frac{1}{2}$ oz. av.): Diluted Acetic Acid 150 parts ($8\frac{1}{2}$ oz. av. or $\frac{1}{2}$ pint). Digest the ammoniac in the diluted acetic acid in a suitable vessel, avoiding contact with metals, until it is entirely emulsified; then strain, and evaporate the strained liquid by means of a water-bath, stirring constantly until a small portion, taken from the vessel, hardens on cooling.—U. S.

The present directions are precise in emulsifying instead of dissolving the ammoniac. To evaporate the liquid until the residue "hardens on cooling" appears to be less definite than to evaporate "to the proper consistence."

The finished preparation is quite adhesive, but has lost nearly all its volatile oil. It must be prepared in porcelain vessels, and during the evaporation, as well as during

the emulsionizing, stirred with a porcelain or glass spatula to avoid contamination with metals.

Medical Action and Uses.—It is used as a stimulant discutient over swellings which have ceased to exhibit an inflammatory tendency, such as *scrofulous joints* and *glands*. It is apt to irritate the skin and produce a papular eruption.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO, *U. S.*, *Br.*— AMMONIAC PLASTER WITH MERCURY.

Ammoniacum and mercury plaster, E.; *Emplâtre de gomme ammoniacque mercuriel*, Fr.; *Quecksilber und Ammoniak-Pflaster*, G.

Preparation.—Ammoniac 720 parts (12 oz. av.); Mercury 180 parts (3 oz. av.); Olive Oil 8 parts (59 grains); Sublimed Sulphur 1 part (7½ grains); Diluted Acetic Acid 540 parts (9 oz. av.); Lead Plaster, a sufficient quantity; to make 1000 parts (16½ oz. av.). Digest the ammoniac in the diluted acetic acid in a suitable vessel, avoiding contact with metals, until it is entirely emulsionized; then strain, and evaporate the strained liquid by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling. Heat the olive oil and gradually add the sulphur, stirring constantly until they unite; then add the mercury, and triturate until globules of the metal cease to be visible. Next add gradually the ammoniac while yet hot; and finally, having added enough lead plaster, previously melted by means of a water-bath, to make the mixture weigh 1000 parts (16½ oz. av.), mix the whole thoroughly.—*U. S.*

Take of ammoniacum 12 ounces; mercury 3 ounces; olive oil 1 fluidrachm; sublimed sulphur 8 grains. Heat the oil, and add the sulphur to it gradually, stirring till they unite. With the mixture triturate the mercury until globules are no longer visible; and lastly, add the ammoniacum, previously liquefied, mixing the whole carefully.—*Br.*

It is obvious that the sulphur merely serves the purpose of facilitating the fine division of the mercury. For incorporating the ammoniac the *U. S. P.* now directs it to be emulsionized with acetic acid, in place of the objectionable boiling with water directed before; the addition of a small quantity of lead plaster, as previously recommended, is a decided improvement. The British Pharmacopœia directs the ammoniac to be liquefied, but omits to state how the liquefaction is to be accomplished.

Medical Action and Uses.—The mercury in this plaster is supposed to add to its discutient effects, and to render it a suitable application to swellings of a *syphilitic* nature. The presence of a syphilitic element is not necessary to render it more efficient than the simple plaster of ammoniac. Its prolonged application sometimes excites *pytialism*.

EMPLASTRUM ARNICÆ, *U. S.*—ARNICA PLASTER.

Emplâtre d'arnique, Fr.; *Arnikapflaster*, G.

Preparation.—Extract of Arnica-Root, 50 parts; Resin Plaster, 100 parts. Add the extract to the plaster, previously melted by means of a water-bath, and mix them thoroughly.—*U. S.*

The official formula, strictly followed, yields a good plaster; the extract of arnica-root has very properly been substituted for that of the flowers, which was formerly directed. In other respects the preparation remains unchanged.

Medical Action and Uses.—Among the plasters which are more frequently procured without the prescription of a physician than with it, this is in popular use as a remedy for a variety of *local pains* which are generally muscular. It serves to protect, support, and mildly stimulate.

EMPLASTRUM ASAFCETIDÆ, *U. S.*—ASAFCETIDA PLASTER.

Emplastrum asæ fetida, *Emplastrum fetidum*.—*Emplâtre d'ase fétide*, *Emplâtre fétide* (*antihystérique*), Fr.; *Stinkasant-Pflaster*, G.

Preparation.—Asafetida 35 parts (14 oz. av.); Lead Plaster 35 parts (14 oz. av.); Galbanum 15 parts (6 oz. av.); Yellow Wax 15 parts (6 oz. av.); Alcohol 120 parts (48 oz. av. or 56 fluidounces). Digest the asafetida and galbanum with the alcohol on a water-bath, separate the liquid portion from the coarser impurities by straining while hot, and evaporate it to the consistence of honey; then add the lead plaster and the wax, previously melted together, stir the mixture well, and evaporate to the proper consistence.—*U. S.*

The present directions, though not quite correct, are an improvement over those of the previous Pharmacopœia, which directed the gum-resins to be "dissolved" in the alcohol. The intention is to disintegrate them, so that by straining they may be freed from the coarser impurities. The plaster is of good consistence.

Medical Action and Uses.—The local stimulation of the galbanum and the action of the absorbed asafetida upon the nervous system render this plaster an appropriate application to the chest in *whooping cough* and to the abdomen in habitual flatulent *colic*. It is recommended in *hysteria*, but can hardly act upon that disease except through the patient's imagination.

EMPLASTRUM BELLADONNÆ, U. S., Br.—BELLADONNA PLASTER.

Emplâtre de belladone, Fr.; *Belladonna-Pflaster*, G.

Preparation.—Belladonna-Root, in No. 60 powder, 100 parts (15 oz. av.); Alcohol, Resin Plaster, each a sufficient quantity; to make 100 parts (15 oz. av.). Moisten the powder with 40 parts (6 oz. av. or 7 fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the belladonna-root is exhausted. Reserve the first 90 parts (13½ oz. av. or 14 fluidounces) of the percolate; evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to 10 parts (1½ oz. av. or 1½ fluidounces); mix this with the reserved portion and evaporate, at or below the above-mentioned temperature, to a soft, uniform extract. Add to this enough resin plaster, previously melted, to make the whole weigh 100 parts (15 oz. av.) and mix thoroughly.—U. S.

Take of extract of belladonna, resin plaster, each 3 ounces; rectified spirit 6 fluidounces. Rub the extract and spirit together in a mortar, and when the insoluble matter has subsided decant the clear solution, remove the spirit by distillation or evaporation, and mix the alcoholic extract thus obtained with the resin plaster melted by the heat of a water-bath, continuing the heat until with constant stirring the plaster has acquired a suitable consistence.—Br.

Of the two formulas, the first, which differs from that of the U. S. P. 1870 only in manipulation, deserves the preference, since it will always yield a handsome preparation, which may be easily managed and which is quite efficacious if good belladonna-root has been employed. It is often used in the form of sparadrap.

Medical Action and Uses.—Belladonna plaster diminishes the circulation of the blood in the part to which it is applied, and thereby, as well as by a direct action on the nerves, lessens pain. It is habitually employed to allay *neuralgic* and *rheumatic pains*, over *inflammatory swellings* in their congestive stage, and especially upon engorged *glands*, as the *mamma* and the *testicle*. Care must be taken that the skin is sound where it is applied, as the characteristic symptoms of belladonna-poisoning of a high grade have resulted from a neglect of this precaution. A very striking case of the kind is reported by Mather (*Med. Record*, xxiii. 82). The symptoms in a mild form, such as dilatation of the pupils, dryness of the throat, and a papular eruption on the skin, are common even when the plaster has been applied to the unbroken skin.

EMPLASTRUM CAPSICI, U. S.—CAPSICUM PLASTER.

Sparadrapum capsici.—*Sparadrap de capsique*, Fr.; *Capsicumplaster*, G.

Preparation.—Resin Plaster, Oleoresin of Capsicum, each a sufficient quantity. Melt the resin plaster at a gentle heat, spread a thin and even layer of it upon muslin, and allow it to cool. Then, having cut off a piece of the required size, apply a thin coating of oleoresin of capsicum by means of a brush, leaving a narrow blank margin along the edges. A space of 4 inches (10 Cm.) square should contain 4 grains (25 Gm.) oleoresin of capsicum.—U. S.

This new pharmacopœial plaster is simply adhesive plaster rendered irritating by a very thin layer of the oleoresin.

Allied Plasters.—EMPLASTRUM AROMATICUM, Emplastrum stomachicum.—Aromatic or stomach plaster, *E*.; *Emplâtre aromatique*, *Fr*.; *Aromatisches Pflaster*, *Magenpflaster*, *G*.—Yellow wax 32 parts; suet 24 parts; turpentine 8 parts. Melt them together, and to the nearly-cooled mass add of expressed oil of nutmeg 6 parts; powdered olibanum 16 parts; powdered benzoin 8 parts;

oil of peppermint and of cloves, each 1 part. Mix intimately, form into rolls, and keep them in wax-paper.—*P. G.* 1872. The plaster is of a grayish-brown color and has an aromatic odor.

SPICE PLASTER, as generally used in the United States, is a mixture of various spices mixed with honey or water, and really belonging to the class of cataplasms. The following formula was used by the late Dr. Parrish, Sr.: Powdered capsicum, cinnamon, and cloves, of each 2 ounces; rye-meal, spirits, and honey sufficient.

Medical Action and Uses.—Capsicum plaster is mildly counter-irritant and decidedly stimulating. It is a convenient and efficient application to parts affected with *muscular rheumatism* or *neuralgia*, and to palliate some internal pains.

Spice plaster is popularly used in Germany to palliate *rheumatic* and other local pains, and deserves to be made official in this country.

EMPLASTRUM CERATI SAPONIS, *Br.*—SOAP CERATE PLASTER.

Emplâtre de savon saturné, Fr.; Seinfencerat-Pflaster, G.

Preparation.—Take of Hard Soap, in powder, 10 ounces; Yellow Wax 12½ ounces; Olive Oil 1 pint; Oxide of Lead 15 ounces; Vinegar 1 gallon. Boil the vinegar and oxide of lead together by the heat of a steam-bath, constantly stirring them until the oxide has combined with the acid; then add the soap, and boil again until most of the moisture is evaporated; finally, add the wax and oil melted together, and stir the whole continuously, maintaining the heat until by the evaporation of the remaining moisture the product has acquired the proper consistence for a plaster.—*Br.*

A similar preparation was formerly (1850) official in the United States, but has been replaced by CERATRUM SAPONIS (which see). To avoid the prolonged unnecessary boiling, A. W. Gerrard (1874) proposed to substitute for the vinegar 18 ounces of acetic acid, which is sufficient to dissolve the oxide of lead; the acetate of lead formed reacts with the soap, forming lead plaster.

Medical Uses.—Soap cerate plaster is used for the general purposes of adhesive plaster, and for supporting and protecting *enlarged joints* and other swollen parts.

EMPLASTRUM FERRI, *U. S.*—IRON PLASTER.

Emplastrum roborans; Emplastrum ferratum s. martiale.—*Chalybeate plaster, Strengthening plaster, E.; Emplâtre d'oxyde rouge de fer, Emplâtre de Canet, Fr.; Eisenpflaster, Stärkendes Pflaster, G.*

Preparation.—Hydrated Oxide of Iron, dried at a temperature not exceeding 80° C. (176° F.), 10 parts (1 oz.); Canada Turpentine 10 parts (1 oz.); Burgundy Pitch 10 parts (1 oz.); Lead Plaster 70 parts (7 oz.); to make 100 parts (10 oz.). Melt the lead plaster, Canada turpentine, and Burgundy pitch by means of a water-bath; then add the oxide of iron, and stir constantly until the mixture thickens on cooling.—*U. S.*

Hydrated peroxide of iron 1 ounce; Burgundy pitch 2 ounces; lead plaster 8 ounces.—*Br.*

The first is an improvement on the old formula in having one-half of the Burgundy pitch replaced by the turpentine, as previously suggested by us. The lead plaster and Burgundy pitch should be melted first, after which the Canada turpentine should be added, and finally the hydrated oxide of iron, the latter being used now in place of the so-called subcarbonate of iron.

Medical Action and Uses.—There is no reason for believing that the iron in this plaster exerts any special therapeutic influence. Its protective, supporting, and stimulant action renders it a useful application to parts affected with chronic muscular and articular *rheumatism*, to the chest during the decline of acute *pleurisy*, to enlarged *glands*, etc.

EMPLASTRUM GALBANI, *U. S., Br.*—GALBANUM PLASTER.

Emplastrum galbani compositum, U. S. 1870; *Emplastrum lithargyri (vel plumbi) compositum, P. G.; Emplastrum diachylum gummatum, F. Cod.; Emplastrum diachylon compositum.*—*Compound galbanum plaster, E.; Emplâtre diachylon gommé, Fr.; Mutterharz-Pflaster, Gummipflaster, Zugpflaster, G.*

Preparation.—Galbanum 16 parts (4 oz.); Turpentine 2 parts (½ oz.); Burgundy Pitch 6 parts (1½ oz.); Lead Plaster 66 parts (19 oz.); to make 100 parts (25 oz.). To the galbanum and Canada turpentine, previously melted together and strained, add, first,

the Burgundy pitch, then the lead plaster melted over a gentle fire, and mix the whole thoroughly.—*U. S.*

Galbanum, ammoniacum, yellow wax, each 1 ounce; lead plaster 8 ounces.—*Br.*

Lead plaster 12 parts; yellow wax 1½ parts; galbanum, ammoniac. and common turpentine, each 1 part.—*P. G.*

The corresponding plaster of the F. Cod. contains also elemi and sagapenum.

By rubbing 30 grains of powdered saffron with sufficient alcohol to produce a pulpy mass, and mixing this intimately with 4 troyounces of galbanum plaster (*U. S. P.*), previously fused, a good substitute for *Emplastrum galbani crocatum*, used in Europe, is obtained.

EMPLASTRUM OXYCROCEUM. S. EMPL. GALBANI RUBRUM. This compound galbanum plaster is frequently used by our German population; it is prepared as follows: Take of yellow wax, resin, Burgundy pitch, each 6 parts. Melt them together with a moderate heat, and to the strained mass add of ammoniac, powdered, and galbanum, each 2 parts, previously liquefied with turpentine 3 parts. Then add an intimate mixture consisting of mastic, myrrh, olibanum, each, in powder, 2 parts, and saffron, powdered, 1 part, and mix the whole together.—*P. G.* 1872. The plaster is reddish-brown and very tenacious.

Medical Action and Uses.—As a more stimulant application than most of the other plasters used for the same purposes, it may be preferred before them in the treatment of various local affections named in the preceding articles.

EMPLASTRUM HYDRARGYRI, *U. S.*, *Br.*, *P. G.*—MERCURIAL PLASTER.

Emplastrum mercuriale.—*Emplâtre mercuriel*, Fr.; *Quecksilber-Pflaster*, G.

Preparation.—Mercury 30 parts (3 oz.); Olive Oil 10 parts (1 oz.); Resin 10 parts (1 oz.); Lead Plaster 50 parts (5 oz.); to make 100 parts (10 oz.). Melt the olive oil and resin together, and, when the mixture has become cool, rub the mercury with it until globules of the metal cease to be visible. Then gradually add the lead plaster, previously melted, and mix the whole thoroughly.—*U. S.*

Take of mercury 3 ounces; olive oil 1 fluidrachm; sublimed sulphur 8 grains; lead plaster 6 ounces. Heat the oil, and add the sulphur to it gradually, stirring until they unite; with this mixture triturate the mercury until globules are no longer visible; then add the lead plaster, previously liquefied, and mix the whole thoroughly.—*Br.*

The extinguishment of the metallic mercury is accomplished in the first formula by the mixture of resin and olive oil; in the second, by the little sulphur combined with the olive oil. Canada or Venice turpentine would have a similar result.

The French Codex gives a formula for *EMPLASTRUM DE VIGO CUM MERCURIO* (*Emplâtre mercuriel dit de Vigo*), which is occasionally used here. It is made by fusing together lead plaster 200 parts; yellow wax and resin, each 10 parts; add thereto the following powders: olibanum, ammoniac, bdellium, and myrrh, of each 3 parts, and saffron 2 parts; also 60 parts of mercury extinguished by 10 parts of turpentine, and finally 30 parts of liquid storax and 1 part of oil of lavender.

Medical Action and Uses.—The virtues of mercurial plaster depend upon its being not only a mechanical support to the affected parts and a mild counter-irritant, but also upon the specific operation of its mercury, whereby it tends to promote the absorption of exudation-matter, both by its direct local action and by its producing on the system a greater or less mercurial impression. Indeed, it not unfrequently occasions soreness of the gums and a degree of salivation. It is frequently employed for the removal of *syphilitic nodes* and *glandular engorgements* produced by the same cause, including those of the *liver*. It appears also to reduce that organ and the *spleen* when enlarged by malarial disease. The Vigo plaster of the French Codex, which is described above, has been applied as a mask to the face during the papular stage of *small-pox*, with the effect of preventing a full development of the pustules and the consequent pitting. The simpler mercurial plaster appears to have been used with equally good results. In both cases the influence of mechanical compression and of the exclusion of light should not be overlooked.

EMPLASTRUM ICHTHYOCOLLÆ, *U. S.*—ISINGLASS PLASTER.

Emplastrum adhesivum anglicum, *Sparadrapum s. Taffetas adhesivum*, *Sericum anglicum*.—*Court plaster*, E.; *Sparadap de colle de poisson*, *Taffetas d'Angleterre*, Fr.; *Englishes Pflaster*, *Klebtaffet*, G.

Preparation.—Isinglass 10 parts (155 grains); Alcohol 40 parts (620 grains or 13½ fluidrachms); Glycerin 1 part (15½ grains); Water, Tincture of Benzoin, each a sufficient quantity. Dissolve the isinglass in a sufficient quantity of hot water to make the solution weigh 120 parts (4½ oz. av.). Spread one-half of this, in successive layers, upon taffeta (stretched on a level surface) by means of a brush, waiting after each application until the layer is dry. Mix the second half of the isinglass solution with the alcohol and glycerin, and apply it in the same manner. Then reverse the taffeta, coat it on the back with tincture of benzoin, and allow it to become perfectly dry. Cut the plaster in pieces of suitable length and preserve them in well-closed vessels. Substituting *Gm.* (15.5 gr.) for *part*, the above quantities are sufficient to cover a piece of taffeta 15 inches (38 Cm.) square.—*U. S.*

This formula has been taken from the German Pharmacopœia of 1872. The taffeta should be stretched upon a frame, so as to present a level surface. For the first two applications the isinglass solution should be warmed merely to above its congealing-point, so that when spread out it may rapidly solidify, and at the same time firmly adhere to, but not pass through, the fabric. The air having access to both sides of the taffeta, each coating will dry readily and uniformly in a dry and moderately warm atmosphere, and should be quite hard before a new application is made. The addition of glycerin to the last portion of the isinglass solution prevents the plaster from breaking and preserves its flexibility for a long time. The tincture of benzoin applied to the reverse side leaves a thin layer of resin, which, in a measure, renders this plaster waterproof; it is, however, advisable to repeat this application once or twice. The plaster should only be removed from the frame when thoroughly dry.

EMPLASTRUM OPII, *U. S.*, *Br.*—OPIUM PLASTER.

Emplastrum opiatum s. cephalicum s. odontalgicum.—*Emplâtre d'opium, Emplâtre céphalique (temporal, odontalgique, calmant).* Fr.; *Opiumplaster, Hauptplaster,* G.

Preparation.—Extract of Opium 6 parts (1½ oz.); Burgundy Pitch 18 parts (4½ oz.); Lead Plaster 76 parts (19 oz.); Water 8 parts (2 oz.); to make 100 parts (25 oz.). Rub the extract of opium with the water until uniformly soft, and add the Burgundy pitch and lead plaster, melted together by means of a water-bath; then continue the heat for a short time, stirring constantly, until the moisture is evaporated.—*U. S.*

Take of opium, in fine powder, 1 ounce; resin plaster 9 ounces. Melt the resin plaster by means of a water-bath; then add the opium by degrees and mix thoroughly.—*Br.*

Both these formulas yield good and efficient plasters, the first being preferable on account of the absence of the insoluble and non-adhesive constituents of opium, and for being rather stronger as far as opium is concerned.

Medical Uses.—This plaster is a convenient form for the local application of opium to painful parts of limited extent—*e. g.* to the face in *toothache*.

EMPLASTRUM PICIS BURGUNDICÆ, *U. S.*—BURGUNDY PITCH PLASTER.

Emplastrum picatum, F. Cod.—*Emplâtre de poix de Bourgogne,* Fr.; *Burgunder Pechplaster,* G.

Preparation.—Burgundy Pitch 90 parts (9 oz.); Yellow Wax 10 parts (1 oz.); to make 100 parts (10 oz.). Melt them together, strain the mixture, and stir constantly until it thickens on cooling.—*U. S.*

The present formula is an improvement on the former one, in that the proportion of wax has been increased one-third, thus diminishing the brittleness of the plaster. The French Codex directs 1 part of yellow wax to 3 parts of Burgundy pitch.

The formula of the British Pharmacopœia for *Emplastrum picis*, or *pitch plaster*, is as follows: Take of Burgundy pitch 26 ounces; common frankincense 13 ounces; resin and yellow wax, each 4½ ounces; expressed oil of nutmeg 1 ounce; olive oil and water, each 2 fluidounces. Add the oils and water to the frankincense, Burgundy pitch, resin, and wax, previously melted together; then, constantly stirring, evaporate to a proper consistence.—*Br.*

Medical Uses.—Burgundy pitch plaster, besides giving mechanical support, is useful through its stimulant and mildly counter-irritant action. The British preparation is the more efficient of the two.

EMPLASTRUM PICIS CANADENSIS, U. S.—CANADA PITCH PLASTER.

Hemlock pitch plaster, Hemlock plaster, E.; Emplâtre de poix de Canada, Fr.; Canada-Pech-Pflaster, G.

Preparation.—Canada Pitch 90 parts (9 oz.); Yellow Wax 10 parts (1 oz.); to make 100 parts (10 oz.). Melt them together, strain the mixture, and stir constantly until it thickens on cooling.—*U. S.*

The increase of one-third in the proportion of yellow wax is, as in the preceding case, a decided improvement.

This plaster has been occasionally prescribed under the incorrect names of *Empl. cicutræ* and *Empl. conii*. *Emplastrum conii*, P. G. 1872, is made by melting together 4 parts of yellow wax and 1 part each of turpentine and olive oil, and before congealing mixing with 2 parts of powdered conium-leaves. The French Codex recognizes two conium plasters, the simplest being the *Emplâtre d'extract de ciguë*, which contains elemi 2 parts, wax 1 part, and alcoholic extract of conium 9 parts.

Medical Uses.—Its uses are the same as those of Burgundy pitch plaster.

EMPLASTRUM PICIS CUM CANTHARIDE, U. S.—PITCH PLASTER WITH CANTHARIDES.

Emplastrum calefaciens, Br.—Warm or warming plaster, E.; Emplâtre de poix cantharidé, Fr.; Pechpflaster mit Canthariden, G.

Preparation.—Burgundy Pitch 92 parts (23 oz.); Cerate of Cantharides 8 parts (2 oz.); to make 100 parts (25 oz.). Heat the cerate as nearly as possible to 100° C. (212° F.) on a water-bath, and, having continued the heat for 15 minutes, strain it through a close strainer which will retain the cantharides. To the strained liquid add the pitch, melt them together by means of a water-bath, and having removed the vessel stir the mixture constantly until it thickens on cooling.—*U. S.*

Take of cantharides, in coarse powder, expressed oil of nutmeg, yellow wax, resin, each 4 ounces; soap plaster 3½ pounds; resin plaster 2 pounds; boiling water 1 pint. Infuse the cantharides in the boiling water for 6 hours, squeeze strongly through calico, and evaporate the expressed liquid by a water-bath till reduced to one-third. Then add the other ingredients and melt in a water-bath, stirring well until the whole is thoroughly mixed.—*Br.*

A. W. Gerrard (1874) recommends the substitution of resin plaster for the soap plaster.

Allied Plasters.—*EMPLASTRUM CANTHARIDUM PERPETUUM, P. G.*—Perpetual cantharides plaster, *E.*; *Emplâtre perpétuel, Emp. vésicatoire anglais, Fr.*; Immerwährendes Zuggpflaster, Ewiges Pflaster, *G.*—Melt with a gentle heat resin 70 parts, yellow wax 50 parts, turpentine 35 parts, and suet 20 parts, and add very finely-powdered cantharides 20 parts and finely-powdered euphorbium 5 parts. It has a greenish-black color.

EMPLASTRUM PICIS IRRITANS.—Irritant pitch plaster, *E.*; *Vésicatoire de Janin, Fr.*; Reizendes Pechpflaster, *G.*—Melt together Burgundy pitch 32 parts, yellow wax and turpentine each 12 parts, and add finely-powdered euphorbium 3 parts.

EMPLASTRUM THAPSIE, SPARADRAPUM REVULSIVUM.—Thapsia plaster, *E.*; *Sparadrap révulsif de Thapsia, Fr.*; Thapsiapflaster, *G.*—Melt together yellow wax 42 parts, common turpentine 5 parts, colophony, Burgundy pitch, and boiled turpentine each 15 parts; strain, and add glycerin and honey each 5 parts, thapsia resin 7.5 parts; when the mixture has become homogeneous spread upon linen.—*F. Cod.*

Medical Action and Uses.—This plaster maintains a mild counter-irritant action greater than that of the simple pitch plaster, but less than is caused by a blister. It is often of signal advantage in chronic affections of the *joints*, chronic muscular *rheumatism*, and chronic diseases of the *chest*. Of the last, chronic *bronchitis* is often greatly benefited by its use, and next to this is chronic *pleurisy*. It is of service in the treatment of chronic pulmonary engorgement due to the presence of *tubercle*, or in that of *broncho-pneumonia*, which so often tends to pulmonary phthisis.

EMPLASTRUM PLUMBI, U. S., Br.—LEAD PLASTER.

Emplastrum lithargyri (simplex), P. G.; *Emplastrum simplex, F. Cod.*; *Emplastrum diachylon simplex.—Diachylon plaster, Litharge plaster, E.*; *Emplâtre simple, Emplâtre de plomb (de litharge), Fr.*; Bleipflaster, *Diachylon-Pflaster, G.*

Preparation.—Oxide of Lead, in very fine powder, 32 parts (16 oz.); Olive Oil 60 parts (30 oz.); Water a sufficient quantity. Rub the oxide of lead with about one-half

of the olive oil, and add the mixture to the remainder of the oil contained in a suitable vessel of a capacity equal to three times the bulk of the ingredients. Then add 10 parts (5 oz.) of boiling water, and boil the whole together until a homogeneous plaster is formed, adding from time to time during the process a little water as that first added is consumed.—*U. S.*

The French and German Pharmacopœias use equal parts of olive oil and lard in place of olive oil alone, which is directed by the British and United States Pharmacopœias. A much greater discrepancy, however, exists in the proportion of the fat to the other ingredients. Calculated for 100 parts of fat, there are ordered of water 100 (*F. Cod.*), 38 (*Br.*), 16.7 (*U. S.*) parts, and sufficient (*P. G.*); of litharge 53.33 (*U. S.*), 50 (*F. Cod.* and *P. G.*), and 43.7 (*Br.*) parts. The last-named amount is decidedly insufficient, and yields a plaster which is and remains sticky. The litharge should be not less than half the weight of the fat used, and in view of its variable quality may very properly be increased somewhat beyond that proportion, as directed by the United States Pharmacopœia.

In view of the importance of this plaster as a basis for many others, it is usually prepared in larger quantities, and an expeditious and successful manipulation is therefore to be preferred to methods which may involve more labor and time. The oxide of lead may be triturated in the kettle in which the plaster is to be made, with a portion of the oil gradually added until a thin, smooth, and uniform pasty mass is obtained, when the oil may be added more rapidly, the trituration being continued. But if the litharge is in very fine powder, as directed by the Pharmacopœia, there is no necessity for such trituration; the litharge, however, may be passed through a sieve for the purpose of removing impurities and breaking up lumps, and sifted directly into the mixture of oil and water, which may at the same time be heated. The whole is then boiled, and frequently stirred to prevent the litharge from settling to the bottom, and a little hot water is added from time to time to supply that which may have evaporated. The mixture has at first a reddish color, which gradually changes until it finally becomes white. From the time it commences to boil the mixture foams, on account of the extrication of the watery vapors, and as the saponification proceeds the foaming increases. Now it requires additional attention to keep up the supply of water, the proportion ordered by the *U. S. P.* being ample for all purposes, and to prevent the mass from becoming overheated, which would interfere with the adhesive qualities of the plaster and more or less darken its color. The temperature may be allowed to rise to about 120° C. (248° F.), but it will be below that point if sufficient water be present. Instead of boiling the mixture, it may be digested in a water-bath, but the formation of the plaster will then require 2 or 3 days, while by the pharmacopœial process it will be completed in little more than as many hours, depending upon the quantity worked. Without the addition of water, litharge will decompose fats, uniting with the fatty acids, but a much higher temperature will be required, and in the absence of water glycerin cannot be separated, but is decomposed. Plumbic hydrate, the hydrated oxide of lead, contains enough water for the separation of glycerin, and its combination with the acids of the oil is effected more readily and at a lower temperature. The relations are similar if the official directions are followed; but the saponification of the fat requires more time, as plumbic hydrate is slowly formed; however, with sufficient attention no secondary decomposition-products are formed. To increase the saponifying action of the litharge a small quantity of acetate of lead is sometimes added, by which the oxide is more readily dissolved, but the addition is not necessary. Since carbonate of lead saponifies fat with greater difficulty than the oxide, the latter should be as free from the former as possible: the carbonic acid is gradually evolved as the saponification proceeds.

Lead plaster may also be obtained by precipitating a solution of soap by sugar of lead, but the plaster thus obtained soon becomes hard and dark-colored. Similar objections exist against the substitution of many other fats for olive oil. As we have seen, the French and German Pharmacopœias sanction the use of equal weights of olive oil and lard.

The process is known to be finished when, after dropping a little of the plaster in cold water and kneading it between the fingers, it is found to be pliable, but not sticky. When this point has been reached the vessel is removed from the fire and allowed to cool somewhat. The temperature may then be reduced by the addition of cold water, and the mass kneaded and rolled out, as described above (see *EMPLASTRA*), into cylinders of any convenient size. The yield is but little more than the weight of the ingredients used.

Lead plaster is of a uniform grayish-white color, but not white, as stated by the U. S. P. and P. G. At a low temperature the plaster breaks with a finely-granular fracture. On keeping, it becomes of a more dingy tint, and superficially changes to yellowish or pale-brownish. As stated above, it should, when warm, be pliable and not sticky, due to unsaponified fat, and it should be entirely free from uncombined litharge, the presence of which is easily recognized by its reddish color or may be detected by the plaster not being "entirely soluble in warm oil of turpentine" (*U. S.*). Chemically, lead plaster is a mixture of oleate and palmitate of lead, containing also stearate if lard has been used in its preparation.

Zinc plaster, in which oxide of zinc is substituted for litharge, has been occasionally recommended; it is most expeditiously prepared by mixing concentrated solutions of 2 parts of white Castile soap and 1 part of sulphate of zinc, digesting the mixture until the decomposition has been completed, and washing out the salt by kneading the mass under water.

Off. Prep.—Empl. ammoniacicum hydrargyri, Empl. asafœtidæ, *U. S.*; Empl. ferri, Empl. galbani, Empl. hydrargyri, *C. S., Br.*; Empl. opii, *U. S.*; Empl. resinæ, Empl. saponis, *U. S., Br.*

Medical Action and Uses.—The oxide of lead in this plaster is its only active ingredient, and hence it is used as a discutient as well as a protective. Owing to the possibility of absorption of the lead, it should not be applied to raw surfaces. It is frequently used to prevent *bed-sores* and the *abrasions* which many forms of surgical apparatus tend to produce. Zinc plaster may be used instead of lead plaster where a large surface is to be covered or the skin is delicate.

EMPLASTRUM PLUMBI IODIDI, *Br.*—IODIDE OF LEAD PLASTER.

Emplâtre d'iodure de plomb, Fr.; *Jodblei-Plaster*, G.

Preparation.—Take of Iodide of Lead 1 ounce; Soap Plaster and Resin Plaster, each 4 ounces. Add the iodide of lead in fine powder to the plasters previously melted, and mix them intimately.—*Br.*

Mr. A. W. Gerrard (1874) showed that thus prepared the plaster contains very little iodide of lead, which is nearly all decomposed by the soap contained in the plaster; he suggests the following modification: Melt together 1½ ounces of resin and 16 ounces of lead plaster, and stir in 2 ounces of finely-powdered iodide of lead.

Medical Action and Uses.—This is perhaps the best form in which iodide of lead can be employed topically for promoting the resolution of indurations resulting from inflammation, and especially from articular *rheumatism*.

EMPLASTRUM RESINÆ, *U. S., Br.*—RESIN PLASTER.

Emplastrum adhæsivum, P. G.—*Adhesive plaster*, E.; *Emplâtre résineux (adhésif)*, Fr.; *Heftpflaster*, G.

Preparation.—Resin, in fine powder, 14 parts (7 oz.); Lead Plaster 80 parts (40 oz.); Yellow Wax 6 parts (3 oz.); to make 100 parts (50 oz.). To the lead plaster and wax, melted together over a gentle fire, add the resin, and mix them.—*U. S.*

Take of resin 4 ounces; lead plaster 2 pounds; hard soap 2 ounces. To the lead plaster, previously melted with a gentle heat, add the resin and soap, first liquefied, and stir them until they are thoroughly mixed.—*Br.*

This is the plaster which, spread upon muslin, forms the spadrapp commonly known as *adhesive plaster* or *sticking plaster*. The relative proportion of resin in the plaster of the U. S. P. is very nearly the same as formerly, but a portion of the lead plaster has been replaced by yellow wax; which is an improvement, the plaster when spread being less brittle in cold weather than formerly. About 2 per cent. more of resinous matter is contained in the plaster of the P. G., which is made by melting lead plaster 100 parts until all the water has evaporated; then adding yellow wax 10 parts and a previously melted mixture of dammar 10 parts, colophony 10 parts, and turpentine 1 part. This plaster is more pliable and adhesive at a low temperature, a quality possessed also by that of the Br. P. For the latter, A. W. Gerrard (1874) suggests that for use in summer one-fourth the quantities of soap and resin ordered should be used; in the spring one-half the quantity will answer, but in cold weather the official proportions are preferable. The *spadrapp commun* used in France is compound galbanum plaster.

Good adhesive plaster should not be sticky at the ordinary temperature; when spread

upon muslin it should be pliable without cracking, and when applied to the skin should adhere firmly.

EMPLASTRUM ADHÆSIVUM EDINBURGENSE is adhesive plaster containing 3 per cent. of black pitch.

Off. Prep.—Empl. arnicæ, *U. S.*; Empl. belladonnæ, *U. S., Br.*; Empl. calefaciens, *Br.*; Empl. capsici, *U. S.*; Empl. opii, Empl. plumbi iodidi, *Br.*

Medical Uses.—Adhesive plaster is chiefly employed for the support of mobile parts, for exerting pressure, for securing the coaptation of *wounds* and *fractures*, for maintaining *surgical dressings*, etc. It is apt to irritate delicate skins.

EMPLASTRUM SAPONIS, *U. S., Br.*—SOAP PLASTER.

Emplastrum saponatum, *P. G.*; *Emplastrum cum sapon.* *F. Cod.*—*Emplâtre de savon.* *Fr.*; *Seifenpflaster*, *G.*

Preparation.—Soap, dried and in coarse powder, 10 parts (1 oz.); Lead plaster 90 parts (9 oz.); Water a sufficient quantity. Rub the soap with water until brought to a semi-liquid state; then mix it with the lead plaster, previously melted, and evaporate to the proper consistence.—*U. S.*

Take of hard soap 6 ounces; lead plaster 2½ pounds; resin 1 ounce. To the lead plaster, melted by a gentle heat, add the soap and the resin, first liquefied; then, constantly stirring, evaporate to a proper consistence.—*Br.*

The proportion of soap directed is 5.6 (*F. Cod.*), 5.8 (*P. G.*), 10 (*U. S.*), and 14 (*Br.*) per cent. The French Codex orders also 4.5 per cent. of white wax, while the German Pharmacopœia uses yellow wax 11.6 and camphor 1.16 per cent. The *U. S. P.* alone requires the soap to be rubbed up with water; the *F. Cod.* and *P. G.* order the soap to be powdered, when it may be uniformly incorporated with the melted plaster by sifting. Soap plaster has a whitish color, and to be adhesive should be nearly free from water, which renders the soap slippery.

The following preparation has been dropped from the *U. S. P.* 1880:

CERATUM SAPONIS.—Soap cerate, *E.*; Cérat de savon. *Fr.*; Seifencerat, *G.*—Melt together soap plaster 2 ounces; yellow wax 2½ ounces; and add olive oil 4 ounces.—*U. S.* 1870.

Off. Prep.—Empl. calefaciens, Empl. plumbi iodidi, *Br.*

Among the unofficial plasters, more or less employed in different sections, the following deserve to be mentioned in this place:

EMPLASTRUM CERUSÆ, s. EMPL. ALBUM COCTUM.—White lead plaster, *E.*; Emplâtre de céruse, Empl. blanc cuit. *Fr.*; Bleiweisspflaster, *G.*—Melt together lead plaster 60 parts and olive oil 10 parts; add finely-powdered lead carbonate 35 parts, and boil with the occasional addition of a little water until a plaster is formed.—*P. G.* The plaster may be obtained in one operation by using in place of the lead plaster the requisite quantities of fat and litharge. A similar composition, containing a little wax and powdered orris-root, is known as *Mahy's plaster*.

EMPLASTRUM FUSCUM, s. EMPL. MATRIS FUSCUM. EMPL. NIGRUM, s. NORICUM, s. MINII ADUSTUM, s. UNIVERSALE. Finely-powdered red oxide of lead 2 parts and olive oil 4 parts are boiled, with constant stirring, until the mass assumes a dark-brown color, when 1 part of yellow wax is added. For some purposes 1 per cent. of camphor is added, when it is known as *Emplastrum fuscum camphoratum*, *P. G.* The plaster is put up in square cakes and in boxes, and is also sold in some parts of the United States as *universal plaster* and *breast plaster*, and as a secret preparation under different names. It is extensively employed by the German population, and known to them as *Mutterpflaster*, *Universalpflaster*, etc. A very similar preparation, but boiled with litharge and twice the above amount of fat, is known in France as *Onguent de la mère Thècle* and *Emplâtre brun*.

EMPLASTRUM MATRIS ALBUM, s. EMPL. LITHARGYRI MOLLE. Melt together lead plaster 3 parts, lard 2 parts, yellow wax and suet each 1 part.—*P. G.* 1872.

EMPLASTRUM (CERATUM) MINII RUBRUM. Triturate 100 parts of powdered red oxide of lead and 3 parts of camphor with 60 parts of olive oil. Add the mixture to yellow wax and suet each 100 parts and olive oil 40 parts, previously heated together, and stir well until it has congealed.—*P. G.* 1872.

LOGAN'S PLASTER. Boil together over a slow fire olive oil 2½ pints, fresh butter 4 ounces, Castile soap 12 ounces, litharge 16 ounces avoirdupois, until the mass has a pale-brown color; then add carbonate of lead 16 ounces, and continue the heat until the plaster is formed; lastly, add 2 drachms of powdered mastich.

Medical Uses.—Soap plaster is generally used to prevent *abrasions, bed-sores*, etc., and, like other plasters containing lead, it possesses some discutient powers. Owing to the thickness of the layer as it is usually spread, it is apt to be moved from its original position, and is therefore not so efficient as adhesive plaster in preventing bed-sores. Soap cerate applied upon appropriate tissues affords mechanical support to joints, while it acts as a sedative of inflammation by promoting transpiration, and possibly by the direct operation of the lead in its composition. It is used to envelop *sprained, gouty, rheumatic, and scrofulous joints*, and as an application to *glandular swellings* and local hypertrophies.

ENEMATA.—CLYSTERS.

Clysmata, Clysteria.—*Lavements, Clystères*, Fr.; *Klystiere*, G.

Clysters are liquid medicines which are injected into the rectum by means of a syringe, and ordinarily consist of water or of infusions mixed with solutions of salts or holding insoluble substances in suspension. They are rarely if ever prepared by the apothecary, but are generally made at the bedside, and the introduction of formulas into the Pharmacopœia serves mainly the purpose of informing the physician of the mode of their preparation.

ENEMA ALOES, Br.—ENEMA OF ALOES.

Lavement aloétique, Fr.; *Aloeklystier*, G.

Preparation.—Take of Aloes 40 grains; Carbonate of Potash 15 grains; Mucilage of Starch 10 fluidounces. Mix, and rub together.—*Br.*

Medical Action and Uses.—It is far from certain that the enema of aloes exerts any special influence, or any that would not be secured equally well by a solution of common salt or of a magnesium salt. Aloetic enemata, when they are intended to purge, should be large, but when they are to be retained to destroy *ascarides* of the rectum or to stimulate the *uterus*, they should not exceed 2 or 3 fluidounces (Gm. 60–90).

ENEMA ASSAFŒTIDÆ, Br.—ENEMA OF ASAFETIDA.

Enema fetidum s. antihystericum, Clyisma tonicum.—*Lavement d'ase fétide*, Fr.; *Asafœtida-Klystier*, G.

Preparation.—Take of Asafetida 30 grains; Distilled Water 4 fluidounces. Rub the asafetida in a mortar, with the water added gradually, so as to form an emulsion.—*Br.*

This is identical with a mixture of equal parts of water and milk of asafetida.

Medical Action and Uses.—The use of asafetida by enema is often the most eligible mode of its administration, on account of the patient's inability to swallow, as in *hysteria*, or because it acts very promptly, as in cases of *intestinal flatus*. The association of aloes with the emulsion of asafetida forms a very useful enema in cases of *constipation* with flatulence. A mixture of the wine or tincture of aloes and tincture of asafetida, sufficiently diluted with water, is far better than the officinal enema made with water alone.

ENEMA MAGNESIÆ SULPHATIS, Br.—ENEMA OF SULPHATE OF MAGNESIA.

Enema catharticum.—*Lavement de sulfate de magnésic*, Fr.; *Bittersalz-Klystier*, G.

Preparation.—Take of Sulphate of Magnesia 1 ounce; Olive Oil 1 fluidounce; Mucilage of Starch 15 fluidounces. Dissolve the sulphate of magnesia in the mucilage of starch, add the oil, and mix.—*Br.*

Medical Action and Uses.—The oil and mucilage in this enema are worse than useless. A simple solution of Epsom or of Glauber salt in water is preferable. It may be used as an evacuant of constipated bowels when a prompt operation is desired, as in cases of obstinate *constipation* or of *congestion of the brain*. For such purposes an enema should always be large.

ENEMA OPII, Br.—ENEMA OF OPIUM.

Enema anodynum s. sedativum.—*Lavement opiacé anodin*, Fr.; *Opium-Klystier*, G.

Preparation.—Take of Tincture of Opium $\frac{1}{2}$ fluidrachm; Mucilage of Starch 2 fluidounces. Mix.—*Br.*

Medical Action and Uses.—The proportion of laudanum or of other liquid opiate in an enema must vary with the age and state of the patient, with the local or general narcotic effect that is sought, etc. As the enema ought to be retained, the quantity of liquid in it should not exceed 2 ounces (Gm. 60); and if designed to affect the system it should consist of water, which is promptly absorbed, and not of starch, which may not be absorbed at all.

ENEMA TABACI, Br.—ENEMA OF TOBACCO.

Lavement de tabac, Fr.; *Tabak-Klystier*, G.

Preparation.—Take of Leaf Tobacco 20 grains; Boiling Water 8 fluidounces. Infuse in a covered vessel for half an hour, and strain.—*Br.*

Medical Action and Uses.—The quantity stated in the formula is intended for one enema. The infusion of tobacco (*U. S. P.* 1870) was stronger than this preparation by one-half, but was prepared in the same way and used for the same internal purposes—that is to say, for producing nausea and muscular relaxation in cases of strangulated *hernia* and promoting alvine evacuations in *ileus*, as well as in the various cases indicated in the article on TOBACCO. About 1 fluidounce (Gm. 32) of the former American preparation was intended to be given at a time. Its use requires caution.

ENEMA TEREBINTHINÆ, Br.—ENEMA OF TURPENTINE.

Lavement térébinthiné, Fr.; *Terpentinöl-Klystier*, G.

Preparation.—Take of Oil of Turpentine 1 fluidounce; Mucilage of Starch 15 fluidounces. Mix.—*Br.*

Medical Action and Uses.—The proportion of oil of turpentine in an enema should vary with the case in which it is used. It is most frequently employed to lessen *tympanitic* distension of the bowels, but is of little use, comparatively, unless the flatus is confined in the colon. It sometimes affords great relief to suffering in *vesical calculus*. It has been used with alleged advantage in certain cases of *amenorrhœa* and to destroy *ascarides* of the rectum. It may be administered during a paroxysm of *hysteria*. When it is intended that a turpentine enema shall be retained, its bulk should be small, and it should also be made into an emulsion with yolk of egg.

EPIGÆA.—TRAILING ARBUTUS.

Ground-laurel, Gravel-plant, May-flower, E.

Epigæa repens, Linné.

Nat. Ord.—Ericaceæ, Ericinææ.

Description.—The trailing arbutus is a prostrate hairy North American shrub about a foot (30 Cm.) long, growing in sandy woods and flowering in early spring. The thin woody stem is covered with a brown bark. The evergreen leaves are alternate, about 2 inches (5 Cm.) long, petiolate, coriaceous, and reticulated; their shape is ovate, the margin entire, the base heart-shaped, and the apex tipped with a short point. The flowers are in small axillary clusters, rose-colored or whitish, fragrant, have a deeply five-parted bracted calyx, a salver-form corolla with the tube hairy inside, ten stamens, and produce five-lobed and five-celled capsules containing numerous seeds. The leaves are inodorous, and have a bitterish and astringent taste.

Constituents.—The leaves contain tannin, which produces a black precipitate with iron salts. Using gelatin as a precipitant. H. K. Bowman (1869) determined its amount to be 3.5 per cent. Jefferson Oxley (1872) proved the constituents to be identical with those of *uva ursi*—namely, *arbutin*, *urson*, and *ericolin*. Formic acid was also found, and a principle having in its behavior to tests some resemblance to gallic acid, without, however, yielding pyrogallie acid.

Medical Action and Uses.—Trailing arbutus has been compared with *uva ursi* and *buchu*; it possesses some astringency, like the former, and has been used for the relief

of *strangury* and *vesical catarrh*. A decoction is prepared with an ounce (Gm. 32) of the dried leaves and stems in a pint (Gm. 500) of water, and given in the *dose* of a wine-glassful three or four times a day.

EPILOBIUM.—WILLOW-HERB.

Herbe de St. Antoine, Fr.; *Weidenröschen*, *Antonskraut*, G.

Epilobium angustifolium, Linné, s. *E. spicatum*, Lamarck.

Nat. Ord.—Onagraceæ.

Origin.—A perennial herb about 4 to 6 feet (1.2 to 1.8 M.) high, and growing in low grounds and woodlands, occasionally also in dry and sunny localities. It is indigenous to North America, Northern Asia, and the greater portion of Europe, and flowers in July and August.

Description.—The root is long, fleshy, yellowish-white, and has a thick bark. The stem is erect, smooth, often reddish, branching above. The leaves are scattered, subsessile, from 3 to 6 inches (7 to 15 Cm.) long, lanceolate or linear-lanceolate, nearly entire, with a marginal vein, smooth, pale-green beneath. The flowers are in a long terminal spicate raceme; the calyx adheres to the long linear four-sided ovary; the four unguiculate petals are spreading, purple-colored or pinkish, and showy. The eight stamens and the style with the long four-lobed stigma are bent downward. All parts of the plant have a mucilaginous and astringent taste.

Constituents.—Analyzed by C. J. Biddle (1877), the usual constituents of plants were found. The astringent taste is due to a tannin which produces bluish-black precipitates with ferric salts. Gallic acid is also stated to be present.

Medical Action and Uses.—The demulcent, tonic, and astringent qualities of willow-herb are said to render it useful in mild or subacute forms of *diarrhœa*. It may be given internally in decoction and applied externally to unhealthy *ulcers*, including *aphthæ*.

The root and young shoots are eaten by the inhabitants of subarctic regions, and in Russia and Siberia the leaves are used in place of tea.

EPIPHEGUS.—BEECHDROP.

Cancer-root, E.; *Orobanche de Virginie*, Fr.; *Krebswurz*, G.

Epiphegus (Orobanche, Linné) *virginiana*, Barton, s. *E. americanus*, Nuttall. *Meehan, Native Flowers*, ii. p. 93.

Nat. Ord.—Orobanchaceæ.

Origin.—A perennial parasite growing upon the roots of beech trees in North America from New Brunswick to Florida and Missouri, and flowering from August to October. It is collected in autumn.

Description.—The subterraneous portion consists of a subglobular scaly tuber $\frac{1}{2}$ inch (12 Mm.) and more in diameter. The stem is 12 to 18 inches (30 to 45 Cm.) high, much branched, angular, with ovate scales at the base of the branches and flowers. The flowers are in long spicate racemes, the lower ones fertile and with a short corolla, the upper ones sterile, with a long tubular and two-lipped corolla, about $\frac{1}{4}$ inch (8 Mm.) long. The stamens are didynamous, and the superior capsule is one-celled, two-valved, and contains numerous minute seeds. All parts of the plant have a pale purplish- or yellowish-brown color, and a disagreeable, bitter, and somewhat astringent taste.

The constituents of the plant have not been investigated.

Allied Plants, belonging to the same natural order, have been medicinally employed in Europe and America. They are all parasitic, destitute of green foliage, and have a more or less bitter, astringent, and nauseous taste. We mention the following North American species:

CONOPHOLIS (OROBANCHE, Linné) **AMERICANA**, Walroth.—*Cancer-root*, *Squaw-root*, E.—It is from 4 to 6 inches (10 to 15 Cm.) high, nearly an inch (25 Mm.) thick, fleshy, yellowish or brownish, covered with pale shining imbricated scales, resembling a pine-cone. The flowers have a curved two-lipped corolla and four exserted stamens. It grows in oak woods.

APHYLLOX UNIFLORUM, Torrey et Gray, s. *Orobanche uniflora*, Linné.—*Naked broom-rape*, E.—It grows in woodlands, has a very short nearly subterraneous scaly stem bearing one or several peduncles about 4 inches (10 Cm.) long, each with a nodding flower having a curved tubular somewhat two-lipped corolla and included stamens. Its color is whitish or pale tawny.

Medical Action and Uses.—This plant appears to be astringent. Dried and powdered, it has been given internally to control *diarrhœa* and applied externally to fun-

gous and unhealthy ulcers. *Conopholis*, as its popular name implies, has been used for similar purposes, and *aphyllon* is credited with analogous virtues.

EQUISETUM.—HORSETAIL.

Prêle, Fr.; *Schachtelhalm*, G.

Equisetum arvense, Linné, and *Eq. hyemale*, Linné.

Nat. Ord.—Equisetaceæ.

Description.—Both plants are leafless, and grow in damp soil in Europe and North America.

E. ARVENSE, common horsetail, has a simple, smooth, fertile stem, appearing in March or April. The barren stems, which alone are used, are slender, about 2 feet (60 Cm.) long, green, jointed, about twelve-furrowed, with simple or compound quadrangular branches bearing at the joints four scales.

E. HYEMALE, scouring rush or shave-grass, has a simple stem about 2 feet (60 Cm.) or more long, round, grooved, the ridges rough, and at the joints with sheaths of about twenty narrow teeth, having a black girdle at the base and tip.

Constituents.—The scouring rush was analyzed by Diebold (1828), who found in it resin, wax, sugar, and other common vegetable principles. John obtained 13 per cent. of ash, 63 per cent. of which (or 8 per cent. of the plant) was silica. The common horsetail gave to Willing (1856) 4.07 per cent. of ash, 41.4 per cent. of which was silica.

Medical Action and Uses.—The various species of *Equisetum* have had the reputation of being diuretic and astringent. It has been used in *dropsy*, *calculus affections*, *hæmaturia*, *nocturnal incontinence of urine*, *diabetes insipidus*, *hæmoptysis*, *diarrhœa*, and *dysentery*, and also as an *emmenagogue*. If too freely used it is said to render the urine bloody, and therefore it should not be given when the urine is high-colored and the general condition feverish. A decoction may be prepared with 1 or 2 drachms (Gm. 4–8) of the dried plant to a pint of water, of which 2 fluidounces (Gm. 64) may be taken several times a day; or, the fresh expressed juice may be given in the dose of from 1 to 3 ounces daily (Gm. 30–90), diluted with water or whey.

ARENARIA RUBRA. It appears that this plant has long been used in Malta and in Algeria as a remedy for *dropsy*, *gravel*, and inflammations of the *urinary passages*, and that its use involves no risk. The large proportion of its alkaline and earthy salts appears to explain its diuretic virtues. It is best administered in decoction or infusion made with 3 per cent. of the dried plant (*Bull. de thérape.*, xevii. 69).

Secale cornutum, P. G.; *Secale clavatum*, *Mater secalis*, *Clavus secalinus*.—*Spurred rye*, E.; *Ergot de seigle*, *Seigle ergoté (noir)*, *Blé cornu*, Fr.; *Mutterkorn*, *Kornmutter*, *Zapfenkorn*, *Hungerkorn*, G.

The sclerotium (compact mycelium or spawn) of *Claviceps purpurea*, *Tulasne*, replacing the grain (produced within the paleæ, Br.) of the common rye, *Secale cereale*, Linné. Steph. and Church, *Med. Bot.*, plate 113; Bentley and Trimen, *Med. Plants*, 303.

Nat. Ord.—Fungi, Ascomycetes.

Origin.—The ergot fungus and similar but probably distinct organisms are met with upon many grasses and species of *Carex* and *Cyperus*. For medicinal purposes that of rye alone is collected. In its development three distinct stages are observed: At the flowering season one or more ovaries in an ear of rye appear covered by a sweet yellowish mucus, the so-called *honey-dew of rye*, which has a disagreeable odor and is avoided by bees, but attracts other insects, mainly ants and beetles, which were formerly considered to cause the disease of the grain. This honey-dew contains innumerable microscopic cells called *conidia*, and a sugar which reduces alkaline solutions of cupric oxide to cuprous oxide, and is a product of decomposition of the constituents of the ovary caused by the developing *mycelium* of the fungus. This is formed of filamentous cells called *hyphæ*, with an outer layer forming a kind of membrane, the *hymenium*, composed of short linear cells, the *basidia*, by which the oblong or oval conidia are separated. In this stage of development it was formerly considered a distinct fungus, and received various names, the best known being *Sphacelia segetum*, *Léveillé*; this is often used as a descriptive term for the first stage, which is completed when the hyphæ have penetrated the lower

part of the ovary and the separation of the conidia ceases; the relation of the sphaecelia to ergot was first made known by Meyen (1841).

The hyphae of the sphaecelia now begin to unite at the base of the ovary into a compact body, which is purplish-black externally, and rapidly grows in length, carrying upon its apex, in the form of a hood, the remains of the ovary and fragments of the sphaecelia-tissue. Occasionally the formation of the honey-dew does not commence until some time after fructification has taken place and the fruit is partially developed; in such a case the ergot will be crowned by a stunted grain. When full grown the second stage of the fungus has been reached, which forms the officinal ergot, or *sclerotium*, and was formerly regarded as a distinct fungus, named *Sclerotium* (*Spermœdia*, *Fries*, *Clavaria*, *Schrank*) *Clavus*, *De Candolle*.

After some months of rest, in the succeeding spring small circular patches of the external layer are loosened and fold back, while at the same time small heads make their appearance, which, at first white, change to yellowish, reddish, and finally purple, and are upon slender, pale-purplish, curved stipes. On the surface of the head small wart-like excrescences are formed, containing the apertures of bottle-shaped cavities or conceptacles, the *perithecia*. Each one of these conceptacles contains a large number of somewhat fusiform cells or spore-sacs, the *asci*, each one of these containing eight filiform spores, which are discharged from the aperture of the conceptacle agglutinated in a bundle.

FIG. 108.

Ergotized Rye.

The formation of the spores takes place about the time of the flowering of rye, and when brought in contact with its flowers the spores develop again the sphaecelia. The spore-producing heads are nourished from the contents of tissue of the sclerotium, which at first becomes loose and spongy from the disappearance of the oil, and finally shrivels and is destroyed. This third and final stage was formerly likewise regarded as a distinct fungus, known, among other names, as *Cordiceps purpurea*, *Fries*, until Tulasne (1853) proved it to be merely the final stage in the development of a fungus, as described above. The production of spores may be observed by leaving the ergot in the open air or by keeping it upon moist earth under a bell-glass; we have noticed it in a damp stoppered bottle containing some ergot.

It will be seen that the officinal ergot is merely the intermediate or dormant state of a fungus named by the different pharmacopœias *sclerotium*, *U. S.*, compact mycelium or spawn, *Br.*, and stromata sterilia (sterile beds), *P. G.* 1872.

The United States imported 7553 pounds of ergot during the fiscal year 1866-67, and during the years 1875-82 an average of 98,326 pounds annually.

Description.—Ergot forms a solid somewhat fusiform body, which is 1 to 1½ inches (25 to 38 Mm.) long, ¼ to ½ inch (3 to 6 Mm.) thick, subcylindrical or often obtusely triangular, tapering at both ends, usually somewhat curved, with three longitudinal furrows and an easily-detached, yellowish, small appendage or hood at the apex. It is externally of a purplish-black color, the surface frequently fissured transversely, internally whitish, with some purplish striæ, of a uniform texture, and breaks readily with a smooth fracture. It has a peculiar heavy odor, particularly when moist or when treated with potassa solution; its taste is oily and unpleasant. It is frequently attacked by a mite, from which it may be preserved by thoroughly drying it and keeping it in well-stopped bottles or by putting a few drops of chloroform into the bottle containing it. Ergot appears to preserve its virtues not much over a year, and should therefore be annually renewed—a precaution which is no longer prescribed by the German Pharmacopœia. Bernbeck (1881) ascertained that the fixed oil obtained with petroleum

FIG. 109.

Ergot: fruiting stage.

FIG. 110.

Longitudinal section of fruiting head, showing conceptacles.

maintaining it. Ergot appears to preserve its virtues not much over a year, and should therefore be annually renewed—a precaution which is no longer prescribed by the German Pharmacopœia. Bernbeck (1881) ascertained that the fixed oil obtained with petroleum

benzin from recent ergot has a neutral reaction, while that from old ergot shows a decided acid reaction to test-paper.

POWDERED ERGOT spoils after a short time, the deterioration being induced by the fixed oil becoming rancid; it should therefore not be kept on hand in the powdered state except for a brief period. According to Mourrut (1877), the powder may be preserved unaltered for a long time by the addition to it of 5 per cent. of benzoin; but the evident change produced in the fixed oil, and probably other constituents, of the powder has caused a number of suggestions to be made looking toward the removal of the oil. For this purpose benzin or ether has been mostly recommended, and the last-named menstruum has been adopted by the P. G.; which authority directs that the powder should be employed only after having been thoroughly exhausted by ether. Ferret (1882) recommends bruising of the ergot, and drying it at 40°C . (104°F .), after which it should be powdered, again dried at 80°C . (176°F .), then exhausted with ether, and dried at 35°C . (95°F .), the heat being gradually raised just to 100°C . (212°F .), when the powder is to be put into small vials. Benzin of a low boiling-point will likewise answer for this purpose. While there can be no doubt that powdered ergot deprived of fixed oil will not deteriorate readily, investigations are still needed as to the effects of the different solvents of the oil upon the other constituents, and to the length of time for which such ergot will retain its activity; Werner (1881) reported its virtues unimpaired after more than two years.

Constituents.—The separation of the constituents of ergot offers peculiar difficulties, which have been in part explained by the recent researches of Buchheim and of Dragendorff (1876); the former regards the active principle as a body somewhat resembling gelatin, and that it is formed from the gluten of rye-ovary, and readily changed by the influence of chemical agents. The latter, in connection with Podwissotzky, has isolated a number of uncrystallizable compounds possessing more or less activity, the most important being *sclerotic acid*, present to the amount of 4 or $4\frac{1}{2}$ per cent., and *scleromucin*, of which 2 to 3 per cent. are obtained, and which is insoluble in alcohol of 40 per cent. by volume. The following principles are less active: *sclererythrin*, the red coloring matter, which was first noticed as peculiar by Winckler, is soluble in alkalies with a splendid murexid color, also in alcohol, ether, and chloroform; it is present in minute quantity ($\frac{1}{100}$ per cent.); *scleroindin* ($\frac{1}{10}$ per cent. of ergot) after drying is insoluble in water, alcohol, and ether, and dissolves with a violet color in potassa or strong sulphuric acid; *scleroerythrin* and *scleroxanthin* are crystallizable, but without medicinal effect; their alcoholic solutions acquire with ferric chloride a violet and afterward blue-red color. Wenzell's pure alka-

FIG. 111.

Ergot.

This multiplicity of uncrystallizable principles seems to support the views of Buchheim, that the low organization of ergot prevents the formation of well-characterized principles, and that those which are formed are easily altered; it may also explain why preparations possessing some activity may be obtained by very different processes. Wiggers's *ergotin* (1830) was prepared from ergot deprived of fixed oil by ether, by extracting it with hot alcohol, evaporating, and washing the extract with water; the yield was about 1 per cent. It resembles cinchonic-red, is soluble in alcohol, but insoluble in water and ether, and is said to have poisonous properties. Bonjean's *ergotin* is soluble in water and in alcohol. (See EXTRACT. ERGOTÆ.) More light was apparently thrown upon the active principles of ergot by the researches of Wenzell (1864), who proved the presence of two alkaloids—*ecboline* and *ergotine*, the former of which is precipitated by corrosive sublimate, and produces decided effects upon the brain and contractions of the muscles, while the less active *ergotine* reduces the pulse and is precipitated by phosphomolybdic acid, but not by corrosive sublimate. Both alkaloids are brownish, uncrystallizable, soluble in water, and have an alkaline reaction and bitterish taste. Ganser (1870) obtained from ergot 0.16 per cent. of ecboline and 0.04 of ergotine, the hydrochlorate of the latter crystallizing in needles. Manassewitz (1867) gives the composition of ergotine as $\text{C}_{50}\text{H}_{72}\text{N}_2\text{O}_3$. The alkaloids, according to Wenzell and Ganser, exist in combination with *ergotic acid*, which is volatile and yields crystallizable salts. Dragendorff (1876), however, regards the two alkaloids as identical; and this seems to have been proven by Blumberg (1878), who found that concentrated solution of ergotine is precipitated by corrosive sublimate in the same way as ecboline, and that this precipitate with the latter alkaloid is not entirely insoluble in

water. Moreover, Dragendorff denies that ecboline, which is entirely free from the compounds mentioned above, possesses any decided physiological action. Another alkaloid, *ergotinine*, soluble in alcohol, ether, and chloroform, was isolated by Tanret (1875) from the fixed oil of ergot prepared with ether by agitating it with acidulated water; Dragendorff could not obtain it. According to Villiers (1878), it has the formula $C_{35}H_{44}N_4O_6$. Blumberg obtained from fresh ergot .12 per cent. of ergotinine, which is crystalline, but soon becomes resinous; oil of vitriol colors it violet-blue, and with Fröhde's reagent it becomes blue and blue-green; in its effects upon frogs it resembles *picrosclerotine* (producing decreased sensibility, paralysis of the extremities, and death without convulsions). This amorphous alkaloid was obtained, together with *fusco-sclerotic acid*, by Dragendorff and Podwissotzky in purifying sclererythrin. That water distilled from ergot, particularly in presence of an alkali, possesses an alkaline reaction was observed by F. L. Winckler (1826); the alkaline principle was subsequently (1853) named *secaline*, but was found to be identical with *trimethylamine* (*methylamine*, according to Ludwig and Stahl). According to Ganser, it does not pre-exist in ergot, but appears to be formed through the decomposition of the protein compounds.

Ergot contains between 28 and 35 per cent. of bland, yellowish, non-drying *fixed oil*, from which warm alcohol removes some *acid resin* and *cholesterin*; the latter was obtained by L. Stahl (1865), and its character proven by Ludwig (1869). Schoonbroodt (1866) found in it *lactic acid*, which, according to Buchheim, often renders ergotine strongly acid. *Formic* and *acetic acids* appear also to be sometimes present. Starch is entirely absent. The ash of ergot amounts to 3 or 4 per cent., and consists almost exclusively of phosphates.

Sclerotic acid and *scleromucin* having attracted some attention as medicinal preparations, we give the process by which they may be isolated: Digest ergot, previously exhausted by ether and absolute alcohol, with water, dialyze, evaporate the dialysate to a syrupy consistence, and treat with sufficient alcohol to obtain a mixture containing 40 to 45 per cent. alcohol, which precipitates the potassium phosphate, while more alcohol, added until the strength is increased to 75 or 80 per cent., precipitates the salts of sclerotic acid, which are soluble in dilute but insoluble in stronger alcohol, and leave about 19 per cent. of ash. The acid is obtained in a nearly pure state by kneading the mixed sclerotates with 80 per cent. alcohol and afterward dissolving them in 40 per cent. alcohol; the solution is mixed with an excess of hydrochloric acid, and after several hours filtered and precipitated with absolute alcohol, whereby the ash is reduced to about 3 per cent., and consists mainly of some silica, manganium, and phosphates of iron and potassium. The acid is not a glucoside, and yields no precipitates with the reagents for alkaloids—except with phosphomolybdic acid a yellow, and with tannin a nearly colorless, one. Sclerotic acid is obtained as a yellowish-brown, tasteless, and inodorous substance, which has a very slight acid reaction and is hygroscopic without being deliquescent. It is very well adapted for subcutaneous injections in doses of 0.03 to 0.045 Gm.

The dark liquid remaining on the dialyzer, when mixed with sufficient alcohol to bring it to 45 or 60 per cent., precipitates the *scleromucin*, which while moist forms a mucilaginous solution with water, but after drying is only partially soluble, differing in this respect from sclerotic acid, which is soluble in all proportions before and after drying. Scleromucin is darker in color, slightly hygroscopic, gummy, inodorous and tasteless, yields 26.8 per cent. of ash, and, like sclerotic acid, contains nitrogen, is not a glucoside, and is precipitated by tannin and phosphomolybdic acid.

Detection in Flour and Bread.—This depends upon dissolving the principles giving a color reaction. According to Hofmann (1878), bread 30 Gm. is grated, macerated in ether 40 Gm. containing 12 drops of diluted sulphuric acid; after 24 hours the clear ethereal solution is agitated with a concentrated solution of sodium bicarbonate, the latter acquiring a reddish-violet color, due to sclererythrin. The percentage of ergot present, according to Poehl (1882), may thus be determined by comparison with the results from mixtures of known composition.

Physiological Action.—*On Animals:* Among the most characteristic and immediate effects of ergot given to dogs in large doses are dilated pupils, tremulousness, staggering, paraplegia, general prostration, tonic and clonic convulsions, and death. When its action is prolonged the chief phenomena observed are these: gradual paralysis of the hind legs, thirst, anorexia, emaciation, imperfect sight and hearing, shedding of the hair, debility and slowness of the heart, and death by exhaustion. Mixed largely with the

food of pigs, it occasions redness of the eyes and ears, then coldness and gangrene of the latter, and also of the tail and limbs. Death occurs usually in convulsions. The action upon birds is even more characteristic: they grow dull and languid; the comb and wattles turn cold, bluish, or ecchymotic, and are ulcerated; black blood flows from the nostrils; the plumage is shed; the pulse and respiration become slower; and convulsions precede death. Upon pregnant animals (Mammifera) the effect of ergot is, among other things, to produce abortion at an advanced period of gestation. Epidemics of abortion in cows have been traced to this cause, and veterinary surgeons employ ergot habitually to expedite languid labor. The internal lesions of animals destroyed by ergot consist of congestion and softening of the lining membrane of the digestive organs; more or less wasting of the muscles in chronic and their rigidity after acute poisoning, the rigidity being especially marked in the hinder limbs; the blood-vessels of the brain are apt to be congested, and in some cases, it is said, the spinal marrow is softened; the lungs are congested and the blood is liquid and very dark.

The attempts which have been made to determine the physiological action of this drug have not been fruitless. Probably on account of the evident control of ergot over hæmorrhage it was long supposed to cause contraction of the arteries; and this power was affirmed by Holmes as the result of experiment in 1870. He injected preparations of ergot under the skin of frogs, and found that there resulted a contraction of the capillaries. These effects have been confirmed by later observers, some of whom have also witnessed the contraction of the retinal vessels of man under the influence of ergot, and more recently by Péton (1878), who employed in his experiments chiefly hypodermic injections of the extracts of Bonjean and of Yvon. He found that they excited the action of the gravid uterus and induced abortion, and that during its operation the blood-vessels, and especially the arteries, of the organ contracted. He attributed both of these effects to the direct action of the drug upon the smooth muscular fibres. He also observed in a rabbit's ear a complete change of color from red to pale under the influence of the preparation, and proved that this anæmiation was independent of any influence exerted by the central nervous system. He further noticed dilatation of the pupil when the agent was injected not far from the eye. It produced corresponding effects upon the muscular coats of the intestine and bladder, in the case of the latter causing sometimes an energetic spirt of urine, and in the former active and apparently painful peristaltic movements. The investigations of Nikitin (1879) led him to quite different results. He claimed that sclerotic acid exhibits all the effects of ergot, and that sodium sclerotate does so likewise, but in a somewhat feebler degree. His principal and most important conclusion is, that the chief action of sclerotic acid is upon the nerve-centres. The usual discord of physiological interpretations is here unusually absolute.

On Man: In doses of a drachm or two the first action of ergot is to occasion more or less vomiting and purging, but its more characteristic effects are headache, fulness of the head, vertigo, drowsiness, and dilatation of the pupils. The pulse falls from 70 to 60, or even less, in a minute, and this reduction may continue for several days, as may also the dilatation of the pupils. The respiration also becomes slower. Examples have occurred of what may be regarded as acute poisoning by ergot. In some cases, besides the above symptoms, convulsions and loss of consciousness by syncope have been observed. In one instance Dr. J. M. Keating (*Med. Record*, xviii. 318) states that nearly half an ounce of fluid extract of ergot was given, in divided doses, in the course of several hours to a woman suffering with post-partum hæmorrhage. Her face turned bluish; the pupils were dilated; the pulse frequent, weak, and sometimes irregular; and there was dyspnoea, with nausea and faintness, and buzzing in the ears. Under stimulants restoration took place. A pregnant woman, in order to produce abortion, took in vain for several months the fluid extract of ergot; she then took "two handfuls of powdered ergot" in a dry state. She vomited a reddish-brown matter, the tongue was swollen, dry, and dark; the temperature 96° F.; the skin was pale at first, and afterward yellow; the pulse was weak and rapid and soft; the respiration was also rapid, but labored; the area of the heart's dulness was increased, its action was rolling, and its rate 150. Death was attributed to progressive heart-failure. Capillary hæmorrhages were found after death in many organs, but not in the brain; the stomach and peritoneal cavity contained blood; the lungs were anæmic and the heart empty (*Phila. Med. Times*, xiii. 104). An occasional and peculiar action of ergot consists in its producing swelling of the face and arms (*Times and Gaz.*, Oct. 1879, p. 397). The oil extracted from ergot by macerating it with ether displays even greater energy in producing the same symptoms, and, in addition, great languor and lassitude, lividity of the skin, painful rigidity of the muscles, and sometimes diuresis.

These effects may continue for several days. The oil exerts no influence upon the gravid uterus, but the residual ergot from which it had been extracted seems to possess the ecboic power of the drug unimpaired.

Ergotism, as an epidemic disease, exhibits the poisonous effects of ergoted rye upon a large scale and in various phases, which probably depend upon the amount of the poison ingested, as is shown by experiments on animals. In one class of cases the cerebro-spinal nervous system is mainly involved, which is indicated by neuralgic pains, formication and numbness of the extremities, paroxysmal flexures and extensions of the limbs, opisthotonos, violent delirium, etc.—symptoms which are succeeded by exhaustion, and sometimes by strabismus and more or less impairment of vision. In fact, the symptoms are very analogous to those associated with lesions, and especially sclerosis, of the posterior columns of the spinal cord. Death may occur in coma or in convulsions. In the other class of cases the nervous system is not conspicuously deranged, but the function of nutrition is impaired. A sense of muscular lassitude and a dull hue of the skin precede graver derangements of nutrition, shown by the formation of gangrenous areas in various parts of the body. They begin most frequently in the thickness of a limb, and afterward form on the superficial parts, extending from the fingers or toes upward, causing these parts to blacken, shrivel, and harden—in a word, to become mummified or affected with dry gangrene. The dead parts may, as in gangrene from other causes, separate, so as to leave a clean wound behind. In a majority of cases, however, the attack is fatal. Gangrene has also been produced by the continued medicinal use of ergot. Debove reports the case of a woman with “chronic nephritis” who took about 4 grains a day of ergot for 20 days, and suffered gangrene of the hands; and Dujardin-Beaumetz relates that having, in a case of typhoid fever, prescribed a daily dose of 15 grains of ergot, the patient had sphacelus of the right hand, but recovered. A similar one is narrated by Boissaire (*Bull. de therap.*, xxviii, 229, 373). In some cases of locomotor ataxia the symptoms have become distinctly aggravated under the use of ergot (*Centralblatt f. Therapie*, i, 227).

In comparing the different grades of the operation of ergot in animals and in man it is evident that the action in both cases is essentially the same, and that it is manifested mainly by the nervous and the circulatory functions. The former exhibits debility of the general and special senses—dilated pupils, spinal paralysis, and general convulsions, usually clonic in type; the gravid uterus is thrown into tonic contractions; the circulatory and nutritive functions are shown to be deranged by the slowness of the pulse, the fall of temperature, the cyanosis of vascular parts, the discharge of dark blood, the occurrence of cutaneous eruptions, the shedding of the hair, feathers, etc., and the gangrene of various parts, but in man of the feet and hands especially.

It may be hence inferred that the primary sensible action of ergot is upon the nervous system, since the lower degrees of its operation interest exclusively the functions of that system, while its more prolonged action gives rise to radical changes in tissue-nutrition. But all the evidence goes to show that the modifications of nervous action are consequent upon a diminished supply of arterial blood to the cerebro-spinal and the ganglionic nerve-centres. This diminished supply of blood is due partly to the sedative operation of the drug upon the heart, and partly to the contraction of the capillaries, which is demonstrable by the ophthalmoscope in the case of the human eye, and is also visible in the frog's foot and in the membranes of the brain and spinal membranes; it is inferred to exist in the spinal cord from the successive muscular spasm and paralysis which affect the voluntary and also the intestinal and uterine muscles, and the loss of vitality, with gangrene, which have been mentioned. It is, however, upon the non-striated muscular fibres, and especially upon those of the arteries and the uterus, that ergot displays its action first and most conspicuously.

Medical Uses.—*In Labor*: Rules have long been in use for the administration of ergot during labor. It may be employed—1, in lingering labors when the child's head is low, the parts relaxed, the pains absent or feeble, and there is danger in delay from hæmorrhage or other alarming symptoms; 2, when the pains are suspended and convulsions set in, venesection being premised; 3, in inevitable abortion; 4, when the placenta is retained by uterine inertia; 5, in post-partum hæmorrhage under like circumstances. The influence of ergot upon the uterus in labor is unlike that of the natural forces: they are intermittent and rhythmical; it is constant and steady, and, as it were, tetanic, and therefore tends to destroy the child by interrupting the placental blood-supply and impeding the foetal circulation. After labors with ergot the uterus is much larger and harder than natural, and remains so for several days. Ergot has been accused of causing rupture of the uterus, but the evidence is incomplete when the drug has been administered according to

settled rules. Disease of the uterus, deformity of the pelvis or spine, and similar conditions forbid its use. No doubt laceration of the perineum and of the os uteri and hour-glass contraction may sometimes be attributed to its imprudent exhibition, as well as prolapse of the uterus or of the rectum. Retention of the placenta is even more apt to occur. In some cases also, perhaps from an overdose of ergot, it has appeared to cause delirium or coma, lividity of the face, muscular rigidity, etc. There is no doubt that ergot is dangerous to the child in proportion to the duration of its action, and that therefore it should not be administered until labor is near its termination. Fatal effects of the drug may occur even when it has not occasioned contraction of the uterus. Children are then born dead, with cyanosed skin and distorted limbs, and the discoloration has followed the use of the oil of ergot, which does not stimulate the uterine contractions. It follows from these facts that the rules above are justified, and that another might be added to them—viz. never to give ergot to expedite labor in larger doses than are necessary to produce that effect. In premature labor the drug appears to be more hostile to the child's life than at term, but is decidedly profitable to the mother. When the uterus is not in action, ergot does not readily excite its contractions; hence it seldom occasions abortion as a direct effect. Indeed, in certain cases when this occurrence is imminent from accidental uterine hæmorrhage small and repeated doses of ergot have appeared to prevent it. It is stated that in the Dublin Lying-in Hospital it is a rule to administer the infusion of ergot immediately after delivery in all cases, and to multiparæ three times a day for 2 days. It is also given in all cases where there is any tendency to flowing, to a relaxed condition of the uterine walls, or to tenderness over the uterine region. The results, it is said, are the prevention of a tendency to subinvolution and the disappearance of threatening inflammatory symptoms.

Ergot has long been known as a remedy for *uterine hæmorrhage* after labor, as well as for *menorrhagia* and bleeding from *cancer* and other diseases of the uterus. In *menorrhagia* it seems to be most efficient when the uterus is in a flaccid condition, as shown, amongst other ways, by the persistence of uterine leucorrhœa between the menstrual periods. It doubtless in all these cases contracts the uterine tissue, but that it acts directly upon the blood-vessels is proved by its efficacy in other forms of hæmorrhage—*gastric, pulmonary, nasal, intestinal, hæmorrhoidal, urethral, vesical, and renal*—and also in *purpura hæmorrhagica*. In all of these cases it probably becomes efficient through its power of contracting the muscular coat of the small arteries of the bleeding part. It may be employed in substance or as a fluid extract by the mouth, or with more prompt effect by the hypodermic injection of ergotin. Full doses should be given. For hypodermic injection a solution may be prepared with 30 grains (Gm. 2) of ergotin, 13 drachms (Gm. 50) of water, and an equal proportion of glycerin. 1 fluidrachm (Gm. 4), containing about 1 grain (Gm. 0.06) of ergotin, may be used hypodermically. It does not cause local irritation, and its effect upon the hæmorrhage is very prompt. Yvon's preparation is said to be the best.

The power of ergot to contract the uterus may be used to expel retained *placentæ*, mural *fibroid tumors, polypi, hydatis*, etc. In regard to the advantages of ergot in the treatment of *uterine fibroids* the reports are very conflicting, but they are fairly represented in the conclusions arrived at by Herman (*Times and Gaz.*, Aug. 1879, p. 205): "1. Ergot will often produce the diminution in size, and sometimes even complete absorption, of fibroid tumors of the uterus, and will, in the majority of cases, relieve their symptoms. 2. These effects will often follow the administration of the drug by the mouth, but will more certainly be produced by its hypodermic injection in the neighborhood of the tumor." Even when the medicine has little or no appreciable effect upon the size of the uterus, it almost always checks the hæmorrhage which is a common and serious symptom of fibroid tumors of that organ. In *uterine hæmorrhage* due to other causes, such as chronic metritis, the menopause, cancer, subinvolution, parturition, abortion, etc., ergot, but more particularly ergotin hypodermically, has proved more completely and promptly successful than any other medicine. It is also useful in treating chronic *endo-metritis* itself. This action, which under certain circumstances may be called tonic, has been found efficient in the treatment of uterine *leucorrhœa*, and even of *amenorrhœa* due to an enfeebled and anæmic state. It is stated that ergot moderates the excessive *secretion of milk*, and it is employed to prevent *mammary abscesses* and the engorgement of the breasts in weaning. It is one of the most efficient remedies in *diabetes insipidus*, in the treatment of which it was first used by Dr. J. M. Da Costa (*Phila. Med. Times*, July, 1875, p. 636), and afterward by Murrell, Rendu, and others in Europe (Garens, *Thèse*, 1879; *Lancet*, April, 1882); in 1882–83, Da Costa reported seven addi-

tional cases, in all of which, save one, a cure was wrought (*Med. News*, xl. 5; xlii. 72), and three other similar cases occurred to Lacy (*Med. News*, xlii. ix.). The medicine sometimes fails entirely. (Compare *Practitioner*, xxix. 209; xxx. 136.) The more distinctly the affection is connected with nervous disorder, the greater is the benefit derived from ergot. In most cases the cure is complete and permanent. It is probably most efficient when associated with belladonna, and should be given in the form of the fluid extract in the dose of a fluidrachm (Gm. 4) three times a day, gradually increased to double that quantity. It is remarkable that in several cases the diminution of the urine was attended with severe pains in the head. In one case (Garens) the polyuria was associated with "interstitial nephritis," and while using the medicine the patient ceased to urinate, and died of apoplexy. Ergot has long been used with advantage in the treatment of *paralysis of the bladder* and in *paraplegia*. Theoretically, it is most appropriate to cases in which hyperæmia of the spinal cord exists, but it would be very difficult, if not impossible, to account for its efficacy in all successful cases upon this ground, particularly since it appears to have been curative in reflex as well as in congestive paraplegia. It should be given in full doses to ensure its beneficial effects. *Incontinence of urine*, depending either upon paralysis or irritability of the bladder or upon enlarged prostate, is palliated or cured by it, according to the nature of the primary cause. It has been found efficient particularly in those cases of retention or incontinence of urine which are so apt to occur in the typhoid state of febrile diseases. Luton (*Bull. de l'Acad. de Méd.*, xxvi. 803) states that in *dysentery* he found that powdered ergot, or ergotin, in the dose of 8 grains arrested the course of the disease; but Dewar (*Practitioner*, xxviii. 361) states that the medicine always increased the *diarrhœa* for which it was given. Its power of contracting the blood-vessels has been exemplified in cases of *enlarged spleen* of malarial origin, and even when it occurred as a symptom of leucocythemia. In simple *goitre*, or vascular enlargement of the *thyroid* gland, the hypodermic injection of ergotin has been followed in many cases by a complete cure. Suppositories containing ergotin are reported to have cured four out of five cases of *hemorrhoids*, although the first effect of the application was to cause pain for an hour or more (Lansing). Hypodermic injections of ergotin have been used by Vidal, Fernand, and others to prevent *prolapsus of the rectum*, both when attended with hemorrhoids and when free from that complication. The injections were sometimes made into the hemorrhoidal tumors, and sometimes into the skin around the anus. A solution of ergotin (1:5) was employed, of which from 15 to 20 drops were used for each injection (*Bull. et Mémoires de la Soc. de thérap.*, 1881, p. 116). A convenient solution may be made with 1 part of ergotin to 3 parts each of water and glycerin. Suppositories containing ergotin have been used in the cases just referred to—with advantage, according to some, but others declare that they are tolerated with difficulty. They may contain 1 part of ergotin to 10 of cocoa-butter and a sufficient proportion of wax. The hypodermic method has been used with advantage in cases of *ingravescent apoplexy* and *mania à potu*, and might probably be applied in the same way in *heat-apoplexy* or *sunstroke*, for which it has been administered by the mouth in India. Several years ago numerous cases of *cerebro-spinal meningitis* were published in which the treatment consisted mainly of a dose every 3 hours of 1 grain of ergotin and $\frac{1}{10}$ grain of extract of belladonna. The results were regarded by the reporter as exceptionally favorable (W. Read). We have not met with any reports which tend either to confirm or invalidate this conclusion. A case of supposed *tubercular meningitis* cured by ergot has been reported (Gibney). It is likewise credited with the cure of certain cases of *typhoid fever* in which active cerebral or cerebro-spinal symptoms existed. Chevallereau claims that the hypodermic injection of ergotin is capable of arresting the course of acute articular *rheumatism* (*Practitioner*, xxvi. 289). According to J. G. Rogers, it is remarkably potent in repressing the excitement of *insanity* depending upon "cerebral plethora, whether active or passive" (*Med. Record*, xx. 503). It is true that he associated with it bromide of potassium or chloral. In nervous *headache*, or *migraine*, there seems to be good reason for believing it to be useful when continued for some time in doses of 6 grains a day, gradually increased to 15 grains (Schumacher). It is claimed that *dilatation of the heart* from impaired nutrition and independent of valvular disease is greatly benefited by this medicine. Used hypodermically in the neighborhood of *aneurismal* tumors, ergotin is credited with having a share in their cure, along with digitalis, electro-puncture, etc. (*Bull. de thérap.*, cii. 505). It has also been used in *whooping cough* with apparent success. Dewar declares that in scores of cases he proved its power to cut short the disease (*Practitioner*, xxviii. 357), and Allan attributes to it a power of controlling other coughs, even that of phthisis

(*ibid.*, xxvi. 291). It is said to relieve impaired vision arising from congestion of the retina and due to excessive strain of the eye in examining minute objects. A solution of 1 part of ergotin in 15 or 20 of glycerin and water has been used as a collyrium in numerous cases of *conjunctivitis*, *keratitis*, and *iritis*, and it is advised that it be applied every 2 or 3 hours, and that in severe cases a rag wetted with the solution should be kept almost constantly upon the affected eye (Planat; Dabney). The action of ergot upon the capillary blood-vessels has been tested in several diseases of the skin, with alleged advantage, by Heitzmann and by D'Enslow (*Boston Med. and Surg. Jour.*, Sept. 1882, p. 253; *Phila. Med. Times*, xii. 873), and especially in *acne rosacea*, *erythema*, *urticaria*, and *prurigo*—affections which are notoriously rebellious to treatment. It seemed useless in *eczema* and *psoriasis*, perhaps because in those affections an exudation exists. Its utility in *purpura hæmorrhagica* has already been noticed. According to Bulkley (*Trans. Med. Soc. of State of N. Y.*, 1876, p. 176), it causes "an almost, if not quite, immediate cessation of cutaneous and other hæmorrhages." He advises 1 or 2 grains of ergotin or 20 or 15 minims of the fluid extract hypodermically once or twice a day, but says that these doses may be more than doubled without harm. It is alleged by Schilling that ergot prevents the tinnitus and deafness occasioned by quinine or by salicylic acid, and also the amblyopia which the former sometimes induces (*Med. News*, xliii. 123). It would be singular if ergot, which is believed to contract the capillaries, were to relieve a symptom supposed to be induced by that very mechanism.

Administration.—Ergot is conveniently administered by making an infusion of 120 grains (Gm. 8) of the drug, coarsely powdered, in about half a pint of hot water, which should be given in tablespoonful doses every 10 or 15 minutes if contraction of the distended uterus is desired or if hæmorrhage from any part is to be checked. The powder may be given in doses of from 5 to 20 grains (Gm. 0.30–1.30) at similar intervals. Bonjean's or Yvon's ergotin may be prescribed in doses of from 1 to 3 grains (Gm. 0.06–0.20) under like circumstances. 1 Mgm. of ergotin is said to be equal to about 1 Gm. of ergot. Hypodermically, it may be administered in warm water with the aid of glycerin. Ergotin is usually taken in capsules. According to Nitikin, *sclerotic acid* possesses all the physiological and therapeutical properties of ergot, and its sodium salt, although feebler, has the same kind of action (*Phila. Med. Times*, x. 167). Robert, on the other hand, maintains that the acid speedily undergoes decomposition and is practically useless. Strumpf found it highly irritating when used hypodermically. It has been used in this manner in the dose of from $\frac{1}{25}$ to $\frac{1}{10}$ gr. (Gm. 0.002–0.006) (*Bull. de théér.*, xciv. 90), and in the dose of from $\frac{2}{3}$ to $\frac{3}{4}$ gr. (Gm. 0.04–0.05) (Dragendorff).

ERIGERON.—ERIGERON.

Fleabane, E.; *Herbe d'érigeron*, *Herbe de vergerette*, Fr.; *Berufkraut*, G.

Bentley and Trimen, *Med. Plants*, 148, 149.

Nat. Ord.—Compositæ, Asteroideæ.

The U. S. P. 1870 recognized two drugs from this genus—one, as ERIGERON, being the leaves and tops of *Erigeron heterophyllum*, Muhlenberg (s. E. *annuum*, Persoon, s. E. *strigosum*, Bigelow), and of *Erigeron philadelphicum*, Linné (s. E. *purpureum*, Aiton); with these two a third species, *Erigeron strigosum*, Muhlenberg (E. *integrifolium*, Bigelow), is frequently collected. The three species inhabit fields and pastures, are common weeds in many parts of Canada and the United States, and are known as *scabious*, *sweet scabious*, and *daisy fleabane*. All attain a height of about 3 feet (90 Cm.), begin to flower in June, and are more or less hairy.

As ERIGERON CANADENSE (CANADA ERIGERON, E.) the leaves and tops of *Erigeron canadense*, Linné, were recognized. This is known throughout North America as *horse-weed*, *mare's tail*, *fireweed*, *butterweed*, *colt's tail*, etc., flourishes in fields and waste places, and has established itself as a more or less common weed in most countries. Three of these species are annuals or biennials, E. *philadelphicum* being perennial. A number of other species are indigenous to the country west of the Mississippi.

Description.—E. PHILADELPHICUM has the radical leaves spatulate and tapering to a margined petiole, the stem-leaves oblong or lanceolate, the upper ones clasping, all somewhat toothed or the upper entire; the few flower-heads on slender peduncles; the numerous rays almost filiform, pale-purple or flesh-colored, and twice longer than the involucre; the pappus consists of a single row of capillary bristles.

E. HETEROPHYLLUM has roundish-ovate, coarsely-dentate radical leaves upon petioles about twice their length; the stem-leaves are ovate-lanceolate or lanceolate, serrate in the

middle, the upper ones smaller, narrowed at base, and sessile; the rays are numerous, white, tinged with purple, narrow, and less than twice the length of the involucre; the pappus is double, the outer row consisting of minute scales.

E. strigosum has the radical leaves spatulate-lanceolate, petiolate; the stem-leaves lanceolate, all nearly entire; the numerous rays white, and twice the length of the involucre; the scanty pappus is double, like the preceding.

The plants are collected in the middle of summer, and have a slight aromatic odor and a bitterish taste.

E. canadense grows to the height of 5 or 6 feet (1.5 or 1.8 M.), but in sterile locations is usually dwarfed and only a few inches high. The stem is bristly-hairy, erect, and much branched; the leaves are lance-linear, hairy, and mostly entire; the flower-heads are small and numerous, have a cylindrical involucre, many capillary ray-florets, which are nearly included in the involucre, and a straw-colored, bristly pappus. It flowers from July to October, and should be collected when in full bloom. It has an aromatic odor and a bitterish somewhat acrid and astringent taste.

Constituents.—*Canada erigeron* contains a notable quantity of volatile oil (see *OLEUM ERIGERONTIS*); the other species contain very little, the yield, as ascertained by F. L. John (1855), being only $\frac{1}{2}$ drachm from 45 pounds of the dry herb; it is described by Procter as greenish-yellow, of a penetrating odor, a bitterish, pungent taste, of the spec. grav. 0.946, and more viscid than the oil of *E. canadense*. The plants contain also a little tannin, mucilage, and other common principles, but other active constituents have not been isolated. Analyses of the different species are desirable.

Pharmaceutical Preparation.—*EXTRACTUM ERIGERONTIS CANADENSIS FLUIDUM*, *U. S. P.* 1870, is prepared like other fluid extracts, the menstruum being alcohol sp. gr. .835; alcohol of .870 to .875 answers equally well.

Medical Action and Uses.—*Erigeron* is a diuretic, and has been used in the treatment of *dropsies* and of various disorders of the *urinary organs*. An infusion may be prepared with an ounce of the plant to a pint (Gm. 32 in Gm. 500) of boiling water, and given in doses of a wine-glassful or more.

Canada erigeron is a stimulant which owes its virtues to a volatile oil that is officinal. It was popularly supposed to have a special action upon the uterus (whence its name "squaw-weed"), and it has been used successfully to arrest *uterine hæmorrhage*. It has also been employed to palliate *vesical irritation* and *strangury* and cure *gonorrhœa*. An infusion may be prepared with an ounce (Gm. 32) of the plant to a pint of boiling water. *Dose*, a wine-glassful. The oil has been used in the dose of 5 drops (Gm. 0.30), repeated at intervals of half an hour, to arrest post-partum hæmorrhage.

ERIODICTYON.—MOUNTAIN-BALM.

Consumptive's weed, Bear's weed, E.

Eriodictyon californicum, *Benth*am (*E. glutinosum*, *Benth*am), s. *Wigandia californica*, *Hooker et Arnott*.

Nat. Ord.—Hydrophyllaceæ.

Origin.—An evergreen shrub 3 to 5 feet (1 to 1.5 M.) high, growing thriftily among the rocks on the mountain-ranges of Central California southward to Northern Mexico. It has axillary and terminal racemose clusters of showy purplish-blue flowers, with a

FIG. 112.

Eriodictyon-leaves, natural size: lower and upper surface.

funnel-shaped corolla and five stamens, and ovoid, semi-transparent capsules supported by the persistent five-lobed calyx and containing about twenty seeds. The leaves are employed.

Description.—The leaves are alternate, petiolate, 2 or 3 inches (50 to 75 Mm.) long, elliptic-lanceolate, sub-entire or finely dentate, with the upper surface smooth, green, and often varnished with a resinous exudation, and the lower surface white, hairy, and delicately reticulated by a network of veins. After bruising the leaves their balsamic odor becomes more apparent; their taste is aromatic, balsamic, and free from bitterness.

Constituents.—The leaves evidently contain *volatile oil* and *resin*. According to H. S. Wellcome (1876), the latter is transparent, amber-colored, balsamic in odor and taste, amounts to from 20 to 30 per cent. of the leaves, and consists of several distinct resins. The same resin covers also the branches. Thal (1883) showed the presence of *ericolin*. (See LEDUM.)

Pharmaceutical Uses.—Wellcome has suggested the preparation from it of a *fluid extract* and a *tincture*, the latter representing 4 troyounces to the pint, using 75 per cent. alcohol as the menstruum. By triturating the resin with powdered French chalk, and following the official process for syrup of tolu, a *syrup* is obtained having a delicious fruity aroma and taste, closely resembling those of the pineapple, due, probably, to the presence of butyric ether in the resin.

Medical Action and Uses.—Although supposed at first to possess medicinal value, it speedily ceased to attract attention. It is said that chewing the leaf masks the bitterness of quinine. It was stated to be very serviceable in atonic *bronchitis*, but worse than useless in the inflammatory form of the disease; but other accounts present the exact converse of this opinion, and a bold ignorance has pronounced it to be a "specific for chronic lung disease and a certain cure for consumption." Its real value as a medicine is not determined.

ERYNGIUM.—ERYNGO.

Button snakeroot, Corn snakeroot, Rattlesnake's-master, E.

The rhizome of *Eryngium yuccæfolium*, Michaux, s. *Er. aquaticum*, Linné.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—The plant grows in pine-barrens and prairies from New Jersey westward to Wisconsin and southward to South Carolina. It has grass-like, nerved and bristly-fringed leaves, the radical leaves being 12 to 18 inches (30 to 45 Cm.) long, those of the stem much shorter; the white flowers are in dense ovate heads, which are larger than the nearly-entire leaflets of the involucre. It blooms in July and August.

Description.—Button snakeroot consists of a short root-stock $\frac{1}{4}$ to $\frac{1}{2}$ inch (6 to 12 Mm.) long, with numerous short branches, terminating with a more or less deeply cup-shaped scar. A transverse section exhibits a large whitish central pith and several short wood-wedges, separated from the bark by a brown cambium-line. Below, the root-stalk is divided into a large number of thin nearly simple rootlets from 2 to 3 inches (5 to 8 Cm.) long, and containing a rather thick and soft whitish medullium. Button snakeroot has a dark-brown color externally, a slight but rather heavy aromatic odor, and a sweetish and somewhat acrid and aromatic taste, recalling that of parsnip, which is probably due to a volatile oil.

Allied Plants.—ERYNGIUM VIRGINIANUM, Lamarch, has linear-lanceolate leaves and a spiny-toothed involucre longer than the heads of bluish flowers. It is biennial, and grows in swampy localities in the vicinity of the coast from New Jersey southward.

ER. CAMPESTRE, Linné.—Eryngo, *E.*; Chardon-Roland, Panicaud, *Fr.*; Mannstreu, Brachdistel, *G.*—A European perennial. Its root is cylindrical, about 2 feet (60 Cm.) long and 1 inch (25 Mm.) thick, with several conical heads, brown externally, and with a thick internally white bark, covering the porous yellowish wood.

Medical Action and Uses.—Button snakeroot has an acrid and aromatic taste, and is reputed to be diaphoretic and expectorant, and emetic in large doses. In Europe *E. maritimum* was once celebrated for its diuretic virtues, as was also *E. campestre*. Both species continue to be used in the treatment of *dropsy*, *gravel*, and *jaundice*. Eryngium may be given in a decoction made with half an ounce (Gm. 16) of the root to a pint of water, and reduced by boiling to half a pint, and given in 1-ounce doses.

ERYTHROPHLÆUM.—SASSY-BARK.

Mancoma-bark, Saucy-bark, E.; *Écorce de mançône*, *Fr.*; *Mancoma-Rinde*, *G.*

The bark of *Erythrophlæum guineense*, Don (*E. judiciale*, Procter), s. *Fillæa suaveolens*, Guillemin et Perrotet.

Nat. Ord.—Leguminosæ, Mimosææ.

Origin.—Sassy-bark comes from a large tree with bipinnate coriaceous leaves, terminal compound spicate racemes of decandrous flowers, and flat legumes with three or four lenticular seeds. The tree grows in Central and Western Africa, and the bark is used by the natives as an ordeal- and arrow-poison.

Description.—The bark is seen in flat or curved pieces, of irregular size, about $\frac{1}{4}$ inch (6 Mm.) thick, covered externally with an uneven warty and fissured corky layer, or deprived of the same, of a dull red-brown color. It is hard, brittle, of a fibrous texture, internally with pale yellowish-brown spots, inodorous, of an astringent, somewhat bitter, and acrid taste, and when powdered excites violent sneezing.

Constituents.—Sassy-bark contains tannin and a red derivative of it, and yields its active principle to water and alcohol (Procter, 1852). Gallois and Hardy (1876) isolated the poisonous constituent by treating the aqueous extract of the alcoholic extract of the bark with an alkali, and exhausting the mixture with acetic ether. This alkaloid, *erythrophleïne*, is colorless, crystalline, soluble in water, alcohol, amylie alcohol, and acetic ether, but nearly or entirely insoluble in ether, chloroform, and benzol. With sulphuric acid and potassium permanganate a violet coloration is obtained, less intense than the one produced by strychnine, and soon changing to dirty brown. The solutions of its salts are precipitated by the usual reagents for alkaloids, including bichromate of potassium, which yields a yellowish precipitate. Harnack and Zabrocki (1882) ascertained that when boiled with acids or alkalies erythrophleïne yields *erythrophleic acid*, which is free from nitrogen and *manconine*, which is a volatile base resembling pyridine and nicotine.

Erythrophloeum coumanga (or *koumanga*) is also a large tree, all parts of which are poisonous, containing an alkaloid which is closely related to erythrophleïne, if not identical with it.

Physiological Action.—*On Animals:* The first systematic experiments with sassy-bark were made in Philadelphia in 1859 by Drs. S. Weir Mitchell and W. A. Hammond. Its most conspicuous effect was general muscular resolution, so that the animal would remain quiescent in whatever position it was placed, even until death in some instances, without exhibiting any evidence of suffering. Indeed, a degree of anæsthesia was observed. If disturbed, it speedily recovered its activity and sought to escape, although its efforts were marked by a certain languor and difficulty which brought it to rest again almost immediately. When a fatal dose was administered the head fell and was caught up again, and at last reposed upon the fore paws; vomiting usually took place, the pupils contracted, the heart became slow and irregular, the respiration quick and labored, and at length death occurred with general convulsions and sudden dilatation of the pupils. Upon examination, the membranes of the brain were found to be highly congested, but there were no other peculiar changes. In 1876 was published an account of experiments with "cassa-bark" performed by Drs. Branton and Pye, which agree with the statement above given, for these authors say: "In cats and dogs it causes restlessness and nausea, succeeded by violent and repeated vomiting. The respiration is very much quickened. The first symptom of any affection of the locomotor organs in cats is a peculiar jerk of the hind limbs, as if something were sticking to the feet and the animal was trying to shake it off while walking; then the gait becomes staggering and the animal ceases to be able to stand. Death generally occurs during a convulsion of an emprosthotonic character, apparently connected with an attempt to vomit. Consciousness seems to be preserved to the last."

In 1876, MM. Gallois and Hardy discovered in sassy-bark and leaves an alkaloid with which they experimented, and obtained the following results: It is a heart-poison. 2 Mgm. injected under the skin of a frog arrest the heart in systole in from 5 to 8 minutes, voluntary muscular movement and irritability remaining unimpaired for several hours. In warm-blooded animals the alkaloid excites convulsive shocks and extreme dyspnoea as consequences of the disorder in the circulation of the blood—*i. e.* of the heart's arrest. After the animal's death this organ is found distended with blood. During the progress of the poisoning the pulse is alternately accelerated and retarded; in the latter state it becomes fuller, in the former small and feeble. Although the heart-muscle is the first to die, the voluntary muscles are nevertheless, in their turn, paralyzed. In these experiments no mention is made of paralysis as a direct symptom of the poisoning, nor yet of vomiting or diarrhoea. More recent experiments of Sée and Rochefontaine led to a number of conclusions, of which the more important are these: Erythrophleïne, used hypodermically in animals, occasions agitation and restlessness, followed by vomiting and prostration. Primarily, the arterial pressure is increased, and the pulse, at first har-

ried and irregular, becomes slow, and then, at an advanced stage of the poisoning, grows increasingly weak and rapid until the final cessation of the heart's action. The respiration is slow and full at first, but, in proportion as the heart becomes accelerated, it also grows very energetic. Respiration and the heart's action generally cease simultaneously, but sometimes the former is renewed after suspension and when the heart has for 2 or 3 minutes ceased to beat. After death the heart is found in diastole, flaccid, and full of blood (*Bull. de thér.*, xeviii. 546; *Med. Record*, xxiii. 59). Harnack and Zabrocki (*Archiv. f. exper. Pathol. u. Pharm.*, xv. 417), on the other hand, liken the action of erythrophleine to that of picrotoxin, and state that both in frogs and mammals it primarily induces a paralytic condition, followed by agitation, and even convulsion of a tetanoid description. Not only does this conclusion differ from that of Sée, but another also which declares that the heart pulsates after the suspension of respiration, and even more vigorously.

On Man: The accounts which were long ago received of the effects produced by the sassy-ordeal agree in certain points, but not in others. In most of them the production of vomiting appears to be the capital phenomenon, for upon its occurrence or non-occurrence the accused was held to be innocent or guilty. "It is supposed that the fetish goes down with the water into the man's stomach, and looks about in his heart for the guilt—that if he discovers the prisoner to be innocent, he comes back with the draught, which is vomited up again, but if he finds the alleged guilt, he remains in the stomach with the water to inflict merited chastisement upon the culprit." According to another account, the accused, after the trial, "is obliged to move his arms and legs, to show that he has not lost the use of them;" and Santas, who first analyzed this bark, states that the sufferer "loses the power of contracting the muscles throughout the body; he is incapable of standing or walking, and the head rolls heavily about the breast and shoulders."

According to Drs. Brunton and Pye, the vomiting produced by sassy occurs whether it be given internally or hypodermically, but purging only in the former case. The paralysis it causes they explain as being due not to a direct action upon the muscles or the motor nerves, or the spinal cord itself, but to the contraction of the blood-vessels, which lessens the supply of blood to these parts. It acts directly upon the ends of the vagus nerve in the heart, and also upon the nerve itself, and much in the same manner as digitalis. But the final slowing of the heart produced by large doses of "casca" is due to the action of the drug upon the ganglionic apparatus contained in the heart itself. It has "a most extraordinary power of contracting the blood-vessels"—not as digitalis has, by stimulating the vaso-motor centre in the medulla oblongata, but by acting either on the blood-vessels themselves, the vaso-motor nerves, or the vaso-motor centre not contained in the medulla. It appears to act as a diuretic by contracting the arteries and so increasing the blood-pressure.

Medical Uses.—When, in 1859, the essay referred to was published, it had an appendix describing the medicinal applications of sassy. It was said to be astringent, narcotic, acrid, cholagogue, and diaphoretic, and to be used successfully in the treatment of *periodical fevers, colic, diarrhoea, and dysentery*. A summary of cases of the last-named disease treated by the medicine appears to demonstrate its possession of marked curative virtues. It was given in tincture and also in extract. While these clinical reports point in one direction, physiological reasons are now given for using the medicine in *cardiac dropsy*, especially when it depends on mitral obstruction, and in cases of *hæmorrhage* due to flaccidity of the capillaries. Sée states that he has used a tincture of erythrophleum in *cardiac asthma* with the effect of rendering "the movements slower and fuller." But "the arrhythmia does not disappear, the pulse is not slowed, the valvular murmurs are not modified, there is no diuresis. As a cardiac remedy it presents no advantage." Experience has not yet determined what medicinal value, if any, this agent possesses.

ERYTHROXYLON, U. S.—ERYTHROXYLON.

Folia coca.—Coca-leaves, E.; *Feuilles de coca*, Fr.; *Cocablätter*, G.

The leaves of *Erythroxylon Coca*, *Lamarek.* Bentley and Trimen, *Med. Plants*, 40.
Nat. Ord.—*Erythroxylaceæ*.

Origin.—Coca is a small shrub 4 to 6 feet (1.2–1.8 M.) high, with numerous spread- ing purplish-brown branches. It has small, yellowish, five-petalous flowers in axillary clusters of three or four, ten hypogynous stamens, and an oblong, scarlet-red, pointed, and smooth drupaceous fruit containing a single albuminous seed. It is indigenous to the mountains of Peru and Bolivia, and is cultivated in both these countries on the

eastern slope of the Andes in damp warm valleys at an altitude of 5000 or 6000 feet; also in some parts of Colombia, Brazil, and the Argentine Republic. The leaves, when collected, are carefully dried in the sun to preserve their green color. About 40,000,000 pounds are annually produced.

Description.—The leaves are alternate, 2 or 3 inches (50 or 75 Mm.) long, 1 to 1½ inches (25 to 37 Mm.) broad, obovate- or oval-oblong, rather obtuse, and frequently emarginate, somewhat narrowed into the short petiole, entire on the margin, rather thin, smooth, the lower surface pale bluish-green, reticulate on both sides, with a prominent midrib, on each side of which is a curved line running from the base to the apex and representing two longitudinal folds. The leaves have a slight but agreeable odor, similar to that of tea, and a somewhat astringent, bitter, and aromatic taste.

FIG. 113.

Coca-leaf: lower surface, natural size.

Constituents.—Wackenroder (1853) showed the presence in coca-leaves of a peculiar tannin, which reacts with a green color upon iron salts, and has since been called *coca-tannic acid*. Gaedeke (1855) isolated a crystalline alkaloid, which was provisionally named *erythroxyline*, and further examined by A. Niemann (1860) and W. Lossen (1865), the name being changed to *cocaine*. It is obtained from the infusion, which has been freed from tannin by acetate of lead and rendered alkaline by soda, by agitation with ether, and by evaporating the ethereal solution. When pure it is in colorless prisms of a strong alkaline reaction, has a bitterish taste, produces a transient numbness upon the tongue, and dissolves in 704 parts of water and in much less alcohol and ether. Its composition is $C_{17}H_{21}NO_4$, and on being heated with concentrated hydrochloric acid it is decomposed into methylic alcohol, CH_4O , benzoic acid, $C_7H_6O_2$, and *ecgonine*, $C_9H_{15}NO_3$, the latter having a sweetish-bitter taste and being soluble in water, but insoluble in alcohol. MacLagan first observed the presence in coca of a volatile alkaloid, which Lossen named *hygrine*; it was obtained by the latter as a

thick pale-yellow oil of a burning taste, a strong alkaline reaction, and an odor resembling that of trimethylamine. The other constituents of coca appear to be of neither pharmaceutical nor medicinal importance.

Off. Prep.—Extr. erythroxyli fluid., U. S.

History.—Coca was used by the aborigines of South America long before their conquest by the Spaniards. They regarded it as a divine gift, employed it in religious ceremonies, and spoke of it as "that heavenly plant which satisfies the hungry, strengthens the weak, and makes men forget their misfortunes." These reasons were sufficient to render it abominable in the sight of the fanatical invaders, who forbade its use and culture. But when they discovered that it enabled the conquered people to perform the work of their taskmasters, they winked at its diabolical origin and virtues.

Physiological Action.—*On Animals:* It seems to result from experiment that in very large doses coca produces tetanic convulsions; that in much smaller doses it causes hyperæsthesia, dilatation of the pupils, and impaired movement, apparently from the loss of co-ordination; that in intermediate doses it diminishes, and then extinguishes, sensibility without destroying motility. According to Bennett, cocaine and the alkaloids of tea, coffee, guarana, and cocoa produce identical effects, in small doses causing cerebral excitement and impaired sensibility, and in large doses an increase of these symptoms, followed by tonic or clonic convulsions. He found that they at first increase, and afterward diminish, the force and frequency of the heart's action; that they affect the capillaries by first contracting and then relaxing them; that they slightly lower and then raise the temperature, increase the salivary secretion, etc. When the alkaloid cocaine is given to rabbits by the stomach, it only slightly disturbs the heart's action or the respiration; but hypodermically administered, even in small doses, it occasions, according to Schroff, violent tonic spasms, extreme dilatation of the pupil, and an increased pulse- and respiration-rate. The experiments of Bennett, on the other hand, performed on frogs and rabbits, show that its direct tendency is to cause spinal paralysis and loss of reflex action. These observations and conclusions are confirmed by those of Van Anrep (*Practitioner*,

xxv. 204), who found that cocaine in moderate doses stimulates the nervous system, in large doses depresses it, and in excessive doses causes general spasm. It dilates the pupil.

On Man: Owing to the small quantity of coca, and that often impaired in activity, which is to be procured in countries where physiological research is practised, the conclusions in regard to its action are somewhat deficient in fulness and precision. Its principal effects are manifested in enabling those who use it to remain for a long time without food, to endure unusual fatigue, and to preserve a cheerful temper. Some of the first historians of its use, as Von Bibra, state that it suspends the appetite for food for some hours, and at the same time greatly increases the muscular strength and endurance. Schroff found that it quickened the pulse and occasioned an agreeable sense of lightness and activity of mind and body, followed by some lassitude and an inclination to sleep. When the proper quantity has been chewed the laborer goes cheerfully to his work and gives no heed to meal-times while the influence lasts. By repeated doses abstinence from food can be maintained for 3 or 4 days. In some persons it produces an exhilarating effect. The celebrated traveller Tschudi and more recent observers found that when taken in infusion it conferred a singular immunity from suffering, and prevented the hæmorrhages which are apt to occur in the elevated passes of the Andes, some of which are 17,000 feet high. Christison, who tested its action among the Highlands of Scotland, observed that it entirely prevented the fatigue which follows severe pedestrian exercise and suspended hunger and thirst during its action. It had no effect upon the mental faculties beyond liberating them from the dulness and drowsiness which fatigue occasions. The most recent testimony quite confirms these statements. Dr. T. E. Charles says (*Times and Gazette*, Aug. 1882, p. 165): "I lately took one guide and three porters with me to the top of Mont Blanc, and supplied each man with 5 Gm. of coca-leaf. They spent about 2 hours on the mountain without a drop of water and with only a limited quantity of wine. Besides the wine, they drank no tea or coffee or other liquid, neither did they use ice or snow. The evidence of these four men is unanimous and explicit as to the great relief they experienced in chewing this leaf, and how much easier it rendered the great exertion required of them by assuaging a tormenting thirst." The experiments of Mason upon himself are of similar import (*Boston Med. and Surg. Jour.*, Sept. 1882, p. 221): "Shortly after taking the fluid extract of the drug I felt slight weakness in the legs, passing away gradually. My spirits were buoyant and walking seemed easier. It seemed to produce a sort of dream-like condition, and I would walk almost automatically at times. I always noticed dilatation of the pupils. I felt fresher in the evening after a long walk when I had taken coca than when I had not, and often noticed a tendency to wakefulness in the former case on going to bed." A native of Colombia, however (Posada-Arango) declares that coca has none of the virtues attributed to it—that the use of it by chewing is a mere distraction, like reading, to make the time pass. Bouchardat also considers that its virtues are merely such as belong to Chinese tea. Scrivener reports: "I have seen hundreds of Indians during my residence in Bolivia who have chewed coca-leaf from youth upward, many of whom had attained their eightieth year, who showed no signs of being affected by the plant." But a very different account is given by competent witnesses of those who use it in excess. It is said to derange the digestion and to induce habitual constipation, with jaundice, loss of appetite, emaciation, and dropsy. It would seem that mental disorder is not frequent, although foreigners unaccustomed to the plant suffer from delirium and hallucinations (Von Bibra). Other reporters add that the mind is affected with imbecility and the muscular system with weakness and trembling, and that the circulation becomes slow, feeble, and intermittent. It may safely be assumed that coca, like alcohol and tobacco, may be useful or poisonous according to the quantity taken and the manner of using it, and that, like tea and coffee, it may in like manner be wholesome or noxious.

So far as experiments have been undertaken, they do not agree in their physiological results. Ott found that during the use of coca for 5 days the solid elements of the urine diminished, while the weight of the body slightly increased. During the experiment the urine contained oxalate of lime. Christison states that it increased the saliva and probably lessened the secretion of the urinary solids. Gazeau, on the other hand, observed that it augmented the excretion of urea and lessened the weight. According to him, its power consists in its sustained excitation of the vital functions, along with an anæsthetic power which lessens the sense of fatigue and hunger. The first and the last conclusions are reasonable, and seem to be confirmed by the experiments of Mason (*loc. sup. cit.*), who inferred from them that the effects of coca include stimulation of the nervous system and retardation of metamorphosis.

In its native country, Colombia, coca is used, precisely as Chinese tea is elsewhere, as a mild stimulant and diaphoretic and an aid to digestion. These are mainly the purposes of coffee, chocolate, and guarana; and experiment has proved that the active constituents of all these productions, "although unlike one another and procured from totally different sources, possess in common prominent principles which are not only almost identical in chemical composition, but also appear similar in physiological action" (Bennett).

Medical Uses.—Coca has been gravely suggested as a means of appeasing hunger and thirst in armies on forced marches and on voyages with insufficient food and water; but the fact is overlooked that hardly enough of it has hitherto been procurable for laboratory experiments, and that tobacco, coffee, and tea, which are abundant, have closely analogous virtues. It has also been proposed for allaying the canine hunger observed in some cases of *epilepsy* and *insanity*, and to appease the thirst in *diabetes*. Opium has generally been used to fulfil these indications. In *melancholia* it may be employed as opium and also cannabis have been, and probably with as little real advantage. Like tea and coffee, it has been found useful in nervous *headache* and in the *typhoid state* of fevers. It is one of the stimulants that may be substituted for opiates in treating the *opium habit*. It is said to have been used in South America to overcome *uterine inertia* and to allay pain and the discharges in *cholera morbus*. It is reported to have been useful in *spermatorrhœa* and *generative debility*, but no proof exists of so improbable a statement. According to one reporter, it is of use in granular *pharyngitis* and in relaxation of the *vocal cords*.

Administration.—The Indian coca-chewer always carries a bag of the leaves hanging from his neck and a small flask filled with ashes or lime. After having withdrawn the filaments from a handful of leaves, he chews them until they are reduced to a pulp; this he forms into a ball, which he pierces with a splinter wetted and covered with adhering ashes. The mass has then acquired a pungent taste which excites copious salivation; a part of the saliva is ejected and a part swallowed. The ball is retained in the mouth for about an hour, and then is renewed with a fresh handful of leaves. For medicinal purposes the most convenient form is an infusion made with about 2 drachms (Gm. 8) of the leaves in 4 fluidounces (Gm. 120) of water. Of cocaine the *dose* is stated to be from $\frac{1}{4}$ grain to 1 grain (Gm. 0.008–0.06), in substance or as an acetate or muriate.

ESSENTIÆ.—ESSENCES.

Alcoolés concentrés, Fr.; *Essenzen*, G.

Two preparations of this class have been admitted into the British Pharmacopœia. They are simply solutions of volatile oils in alcohol, and are therefore identical with, except that they contain a much larger amount of volatile oil than, the official spirits. The volatile oils are in France usually termed *essences*, while the spirits containing volatile oils, but prepared by distillation, are called *alcoolats*, and those made by simple solution of volatile and non-volatile substances are known as *alcoolés*. The *Essenzen*, popularly so called in Germany, are often strong tinctures or strong solutions of volatile oils, or mixtures of the two.

ESSENTIA ANISI, Br.—ESSENCE OF ANISE.

Alcoolé d'anis concentré, Fr.; *Anisessenz*, G.

Preparation.—Take of Oil of Anise 1 fluidounce; Rectified Spirit 4 fluidounces. Mix.—Br.

Medical Action.—(For medical uses see SPIRITUS ANISI.)

ESSENTIA MENTHÆ PIPERITÆ, Br.—ESSENCE OF PEPPERMINT.

Alcoolé de menthe poivrée concentré, Fr.; *Pfefferminz-Essenz*, G.

Preparation.—Take of Oil of Peppermint 1 fluidounce; Rectified Spirit 4 fluidounces. Mix.—Br.

Medical Action.—(For medical uses see SPIRITUS MENTHÆ PIPERITÆ.)

EUCALYPTUS, U. S.—EUCALYPTUS-LEAVES.

Feuilles d'eucalyptus, Fr.; *Eukalyptus-Blätter*, G.

The leaves of *Eucalyptus globulus*, *Labillardière*. Bentley and Trimen, *Med. Plants*, 109.

Nat. Ord.—Myrtaceæ, *Leptospermæ*.

Origin.—This is the *blue-gum tree* of Tasmania, which was discovered by *Labillardière* in 1792. It grows on moist slopes of wooded hills in the southern half of that island, and in Victoria on the mainland of Australia; it was introduced into Europe in 1856, and has since then been very extensively planted in the southern part of Europe, in Northern Africa, in the Southern United States, and in California. It is a rapid grower, and attains a height of 200, and occasionally even of over 300, feet (60 and 90 M.). The flowers are upon short and broad axillary peduncles, either solitary or in clusters of two or three. The buds are covered with a whitish bloom, and consist of a top-shaped, ribbed, and warty calyx-tube covered by a so-called operculum, which is composed of the united petals, is hemispherical in shape and prolonged into a cone, and separates entire like a lid from the calyx-tube. The flowers are hermaphrodite, with numerous stamens inserted on a disk, a short style, and a four- or five-celled ovary united with the calyx-tube.

Description.—The leaves of young plants are opposite, shortly petiolate, broadly oval or oblong, rather obtuse, heart-shaped at base, and of a pale bluish-green color. They are not employed medicinally. Older trees have the leaves alternate, petiolate, falcate, lanceolate, or oval-lanceolate, rounded and oblique at the base, very entire, and above gradually tapering to the acute apex. They have a length of 6 to 12 inches (15

FIG. 114.

Eucalyptus globulus, *Labillardière*: leaf, about half natural size.

to 30 Cm.), are thick, leathery, and of a pale yellowish-green or gray-green color, contain numerous pellucid oil-glands, are straight feather-veined, and have, besides the prominent midrib, two lateral veins near the margin. The leaves have a peculiar strong balsamic, camphoraceous odor, and an aromatic, bitterish, pungent taste, followed by a sensation of coolness.

Constituents.—Hartzer (1876) obtained from the leaves tannin, cerylic or an allied alcohol, a crystallizable fatty acid—the sodium salt of which is soluble in ether—and three resins, one of which has acid properties, and yields with sulphuric acid a carmine-colored copulated acid, becoming violet with ether. E. S. Wayne (1876) likewise isolated an acid resin, which he found to be crystallizable and to give a brown-red reaction with ferric chloride. The most important constituent, however, is the volatile oil, of which the leaves yield about 6 per cent. (See *OLEUM EUCALYPTI*.)

Off. Prep.—Extract eucalypti fluid., U. S.

Physiological Action.—*On Animals:* The real action of this medicine is yet to be determined, for the reported results of experiments with it are the reverse of harmonious. While one observer states that the oil and the extract do not appear to occasion any special phenomena, unless they perhaps increase the appetite, another declares that in pigeons and rabbits the former produces general excitation, and in excessive doses may prove fatal by paralyzing the excito-motor function, like bromide of potassium, rendering respiration irregular and intermittent, and at last suspending it before the heart ceases to beat. According to Siegen, it depresses the temperature even more than quinine, for 20 grains of the oil caused a rabbit's temperature to fall 3° F., and 120 drops reduced the evening temperature of a healthy man nearly 1° F. Dr. Bernard Berens, Jr. (*Inaugural Thesis*, Univ. of Penna., 1880), deduced from his experiments, upon frogs chiefly, the following among other conclusions: 1. The oil of eucalyptus increases the respirations at first, and then slows them until it destroys life. 2. It does not occasion convulsions. 3. It causes adynamia by acting both upon the muscles and the spinal cord. 4. It suspends reflex action through the latter operation. 5. It diminishes or abolishes

muscular contractility when applied locally or through the circulation. 6. It has no marked action on the nerves themselves. 7. In small doses it increases the blood-pressure and slows the pulse. 8. In large doses it lowers the blood-pressure, and at first quickens the pulse, but in excessive doses it directly slows the pulse. 9. As a rule, it lowers the temperature. 10. It has no action upon the pupil. 11. It is eliminated by the lungs, skin, and kidneys.

On Man: When the oil is taken internally it excites a sense of warmth in the fauces and stomach, with increased salivation and subsequent eructations of gas, but in doses of from 15 to 20 grains it is readily tolerated. It is apt to cause some fulness of the head and vascular excitement. It seems to be eliminated through the lungs. It does not impart to the urine a peculiar odor unless given in tincture and in large doses, and no resinous matter is detected in the urine by nitric acid, as is the case when copaiva is taken. According to Guibert, it eliminates an enormous proportion of urea. We are informed also by him that in doses of 20 drops the oil causes general stimulation, a feeling of lightness, and an irresistible desire to keep moving, together with a remarkable suppleness of the back and limbs. The spirits are raised and the mind is clear and active; the appetite is increased, and sometimes aphrodisiac effects are observed. To use this author's words, "there is a true medicinal intoxication," which is not followed by a corresponding depression. In doses relatively or absolutely excessive there is more or less general muscular paresis, without mental depression, and easily dissipated by coffee or alcohol. It is theoretically held to promote the capillary circulation by dilating the capillaries, and thereby rendering the pulse more frequent. Applied to the raw skin, it causes burning pain.

Medical Uses.—Eucalyptus has been very extensively used as a remedy for *intermittent fever*. As in all similar cases, the discovery of its virtues was accidental. It is alleged that more than 40 years ago the crew of a French man-of-war, having lost a number of men with "pernicious fever," put into Botany Bay, where the remaining sick were treated with eucalyptus and rapidly recovered. It is also said that the virtues of the tree were well known to the aboriginal inhabitants. In 1867 some peasants of the Spanish province of Valencia were found to be using the leaves of the plant to cure fever and ague. In the following year Dr. Brunel of Montevideo was led by reports of this experience to employ it in hospital practice, and especially by such statements as the following of Dr. Ramel of Valencia: "I assure you that 4 leaves of this precious plant infused in water form an excellent febrifuge. The sick as soon as they find themselves attacked hasten to procure these leaves, and in no instance do they fail, contrasting strongly with cinchona, which not only is often unavailing, but often also does not prevent a relapse." The report of Dr. Brunel is scarcely less glowing and positive. In 1871, Dr. Keeler, an official physician of certain Austrian railways in malarious districts, affirmed that it was quite as efficient as cinchona. Others have attributed to it marvellous results in cases in which cinchona failed. Others, still, conclude that it is peculiarly curative in the inveterate forms of the disease. There were not wanting, however, physicians who doubted the published reports, some of them upon the ground of their own experience; and among them one, at least, accounts for their discrepancies by supposing that different species of Eucalyptus had been employed, and that *E. latifolius* is generally inefficient, while *E. longifolius* seldom fails (Oeffinger). We regard the report of Burdel as probably the most accurate and satisfactory. His field of observation was in one of the most marshy departments of France, La Sologne, where periodical fevers are exceptionally ripe and grave. He put the alleged remedy to a prolonged and thorough test, and concluded that it possessed little or no curative power over intermittent fever. Out of one hundred and twenty-three cases only eleven were cured without relapse, and these were, moreover, treated in a hospital; and it is well known that intermittent-fever patients, on being removed from a malarial locality, are very apt to recover without any medicinal treatment at all. And, still further, it was observed that among those whose paroxysms ceased under the use of this medicine there was no diminution of the malarial cachexia, such as usually takes place after the treatment by quinia. In a report on its use in the British East Indian army it would seem to have failed in more than half the cases (Roberts). On the whole, there does not appear to be any substantial reason for believing that a substitute for cinchona has been found in eucalyptus.

It has been alleged that this tree has a special power of destroying malaria in the localities where it grows, but as the statement still lacks confirmation, it is unnecessary to refute the causes assigned for this effect—viz. "that its dead leaves, etc. raise the soil; that it energetically absorbs the soil-water in consequence of its very rapid growth and the multitude of stomata that stud its leaves; and, finally, that it protects the soil against

the extreme solar heat so favorable to the generation of animalculæ" (Gubler). These reasons would be equally valid as proofs of its power to generate malaria. The improvement that has taken place in the sanitary state of certain malarial localities where the eucalyptus has been planted is real, but it should be remembered that all arboriculture has a similar effect. The extremely rapid growth of the eucalyptus may render it peculiarly efficient.

As a summary of the virtues claimed for this medicine the following may be cited: "Not being an irritant, it may be liberally used in all cases of hospital *gangrene* and other gangrenous affections, of fetid suppuration, such as occurs in glanders, syphilis, abscesses connected with dead bone, etc. It may be used with advantage to prevent animal and vegetable putrefaction, and hence as a *deodorizer* of hospital wards. Internally, it may be given in all cases of *ulcer* of the *stomach* or *bowels*, in *septicæmia*, *typhoid fever*, *scarlatina*, *pulmonary gangrene*, *fetid bronchitis*, etc." To this enumeration may be added cases of *fetid lochia*, *ozæna*, and *cancer of the tongue*. It would seem to be useful in *utrine* and *vesical catarrh* and in *gonorrhœa* and *gleet*, and in some cases apparently of chronic *ulcer of the stomach* it has arrested the vomiting and enabled the patient to retain and digest food. According to Mosler, a solution of 1 part of eucalyptus oil in 5 of alcohol and 35 of water forms an efficient liquid, when atomized, for inhalation in *diphtheria* (*Times and Gazette*, Aug. 1879, p. 214; Gibbes, *Am. Jour. Med. Sci.*, July, 1883, p. 244). It seems quite possible that the 5 parts of alcohol would be more efficient than the 1 part of oil in this liquid. A similar criticism is suggested by the alleged virtues of eucalyptus oil as a vulnerary. Schultze used as a dressing for *wounds* a mixture of 1 part of this oil to 9 parts of olive oil (*Bull. de thérap.*, xcix, 430). As a rationale of its mode of action we are told that if a person is kept under its influence the blood drawn from his veins will not undergo putrefaction. "At all events, the hæmato-globulin is expelled from the globules and becomes oxidized externally to them, and the anatomical element is, as it were, embalmed." It is somewhat difficult to conceive that the sick of any disease should profit by the mummification of their blood-corpuscles.

Undoubtedly, eucalyptus, and especially its oil, tend to restrain putrefactive fermentation, as all aromatics have been known to do since the beginning of history; and very possibly these new agents may excel the old in this respect. Certain it is that the oil is a most efficient deodorizer, and, having a very agreeable perfume of its own, is capable of substituting a pleasant for an offensive smell, while its stimulant operation upon diseased tissues assists them in recovering a natural mode of action. As an *antiseptic* dressing many surgeons have employed it as a substitute for carbolic oil, and it is stated to have been approved by Mr. Lister (*Lancet*, May 21, 1881). It has been inhaled with great advantage in an atomized solution in cases of *gangrene of the lung* and of *fetid bronchitis*, and applied on tampons it corrects the *fœtor* of *lochia* and other uterine discharges (Sloan, *Lancet*, Sept. 2, 1882). Similar applications of fluid extract of eucalyptus and glycerin are said to be very efficient in relieving *pain* in displacements and other painful disorders of the uterus (*Amer. Jour. Med. Sci.*, Oct. 1882, p. 397).

It has been claimed that tincture of eucalyptus will cure *whooping cough*, but there is no adequate proof of its efficacy. Its astringent and balsamic qualities naturally suggested its use in the topical treatment of various affections in which other medicines of like qualities had been found useful, especially in alcoholic tincture. But it cannot be doubted that the alcohol had a potent influence in the treatment by tincture of eucalyptus of slight *hæmorrhages*, *mucous profluvia*, *leucorrhœa*, *gonorrhœa*, indolent and irritable *ulcers*, *spongy gums*, etc. In certain of these affections, especially in *ulcers*, the fresh bruised leaves deprived of their nerves have been found to cause sufficient stimulation to promote a cure.

It is alleged that smoking the dried leaves of eucalyptus in a pipe or cigar is, with the exception of hypodermic injections of morphia, the most efficient means of calming irritation and procuring sleep in *cardiac* and *aneurismal asthma*, and particularly in cases of pressure on the vagus or its branches by thoracic aneurisms (Maclean). When the patient is too ill to inhale actively he may be kept in an atmosphere filled with the smoke of the burning leaves. The tincture of eucalyptus is said to remove the fishy flavor and smell from *cod-liver oil* when added in the proportion of 1 part to 100. The leaves are strewn among woollen clothing to protect it from *moths*.

Administration.—The leaves may be applied fresh and bruised or mixed with poultices. They may be given internally in doses of 5 grains (Gm. 0.30) or more, but efficient doses of them are too bulky for convenient use in this manner. The extract is very apt to derange digestion and occasion diarrhœa. The *dose* of the oil may be stated

at from 2 to 5 drops. The tincture is the most agreeable form of the medicine; it may be prescribed in doses of 15 or more minims (Gr. 1). Topically, the oil may be diluted with alcohol or oil or incorporated with the ordinary constituents of suppositories.

EUONYMUS, U. S.—EUONYMUS.

Cortex euonymi.—Wahoo, *Spindle tree*, *Burning bush*, E.; *Écorce de fusain (de bonnet de prêtre)*, Fr.; *Spillbaumrinde*, *Spindelbaum*, *Pfaffenhütchen*, G.

The bark of *Euonymus atropurpureus*, *Jacquin*.

Nat. Ord.—Celastraceæ.

Origin.—The wahoo is a shrub 6 to 10, or even 14, feet (1.8 to 3 or 4.2 M.) high, and is found in shady woods of the northern and middle section of the United States east of the Mississippi. As an ornamental shrub it is of a strikingly handsome appearance in autumn from its copious crimson, smooth, four-lobed capsules, which are pendulous on long peduncles. Its branches are slightly quadrangular, the leaves opposite, petioled, elliptic-ovate, serrate, and pointed; the flowers are dark-purple, in loose cymes of three to six, and appear in June. The root-bark is preferred.

Description.—It comes in curved or quilled fragments varying in thickness between $\frac{1}{16}$ and $\frac{1}{8}$ inch (1.5 and 3 Mm.). It is externally of a light ash-gray color, mottled with larger or smaller patches, or fine longitudinal scaly ridges and meshes, brown or blackish cork, detaching in very thin and small scales. The inner surface, to which fragments of the white wood are often adhering, is pale brownish-white and smooth. When dry the bark breaks, both transversely and longitudinally, with a nearly smooth fracture, exhibiting a whitish and pale-brownish tissue, which in the inner layers has a distinct tangential arrangement. The bark attracts moisture in a damp atmosphere, thereby losing its brittleness, is nearly inodorous, and has a sweetish afterward bitterish and somewhat acrid taste.

Constituents.—W. P. Clothier (1861) isolated bitter, yellow, acicular crystals from the tincture prepared with diluted alcohol by agitating it with chloroform. The same principle is probably contained in the so-called *euonymin* of the eclectics, which is obtained by precipitating a concentrated tincture of the bark with water. W. T. Wenzell (1862), however, obtained by treatment of the tincture with chloroform a dark-yellow substance from which ether dissolved a golden-yellow resin; the insoluble portion was dissolved by alcohol, a resin precipitated by acetate of lead, and the lead removed from the filtrate; on evaporation, uncrystallizable *euonymin* was left, having an intensely bitter taste. It is a neutral principle soluble in ether (?), alcohol, and water, and precipitated by subacetate of lead and phosphomolybdic acid. Wenzell obtained also *asparagin*; *euonic acid*, which crystallizes in needles and is precipitated by subacetate of lead; tartaric, malic, and citric acids; several resins, starch, pectin, and other common vegetable principles. The dried bark left 14.75 per cent. of ash, about half of which consisted of silica.

Allied Drugs.—*EUONYMUS AMERICANUS*, *Linné*—Strawberry bush, E.—is a low, usually trailing shrub, with crimson warty capsules and orange-red roots.

EUON. EUROPEUS, *Linné*, is 8 to 20 feet (2.4 to 6 M.) high, occasionally cultivated in gardens, has greenish-yellow flowers and pale-red capsules, the arillus being orange-red. All parts of it are emetic and purgative; the fruit, made into an ointment, has been used for the destruction of pediculi. Riederer (1833) believed the bitter taste to be due to an alkaloid, *euonymine*, which he did not succeed in obtaining pure. Grundner (1847) regarded it as a mixture of resin with bitter extractive. The arillus yields by pressure an orange-colored oil which has a bitter taste. The orange-red coloring matter, which is quite prevalent in this natural order, seems to deserve careful investigation.

Medical Action and Uses.—*Euonymus* was formerly reported to be "tonic, a hydragogue cathartic, diuretic, and anti-periodic." This barbarous jumble of incongruous qualities is now replaced by one which belongs to euonymin, in common with many other purgatives which also increase the secretion of the bile, especially aloes, colocynth, and rhubarb, and many other medicines which are not purgatives, such as colchicum, ipecacuanha, nitro-muriatic acid, phosphate of ammonium, benzoate and salicylate of sodium, and phosphate of sodium, which last is only feebly laxative.

According to Rutherford (*Physiological Action of Drugs on the Secretion of Bile*, 1880, p. 45), "5 grains of euonymin, mixed with a small quantity of boiling water and placed in the duodenum of dogs, powerfully stimulated the liver." In these animals it only slightly increases the intestinal secretion, but is an active purgative in the human subject. Whether, therefore, it is a cholagogue in man is not yet demonstrated. We are indeed

assured that one practitioner has prescribed it "in over fifty cases of *biliary derangement* and *sick headache*, and finds it of much value" (*Practitioner*, xxiii. 336); and another declares it to be "one of the best remedies in the materia medica, when used in small doses, for torpidity of the mucous membrane and liver, for hæmorrhoids with torpidity of the peristaltic action of the bowels, and in the 'erysipelatous diathesis'" (*Edinb. Med. Jour.*, xxvii. 175); but what is meant by "biliary derangement," or "torpidity," etc., it is impossible to define; and the impression remains that it signifies mainly *constipation*, which any familiar and thorough purgative, such as the compound cathartic pill, would be adapted to remove, or podophyllin, whose action upon dogs seems to be almost identical with that of euonymin. On the whole, neither wahoo-bark nor its purgative principle can be said to possess any peculiar virtues. Either is an active and useful purgative, but nothing more.

A decoction or an infusion of euonymus may be prepared with an ounce of the bark to a pint (Gm. 32 to Gm. 500) of water, and given in the *dose* of a wine-glassful. The average dose of euonymin is 2 grains. It is usually taken at bed-time, and followed the next morning by a saline purge, which should be sulphate of sodium, according to Rutherford, a "hepatic stimulant," and not sulphate of magnesium, which the same authority assures us "has no cholagogue action."

Griffith states (*Med. Botany*) that *E. americanus*, *E. europæus*, and still other species, including *E. atropurpureus*, "have similar properties; the seeds are all nauseous, purgative, and emetic, and are used in some places to destroy vermin in the hair; the leaves are poisonous to sheep and other animals feeding on them."

EUPATORIUM, U. S.—EUPATORIUM.

Herba eupatorii perfoliati.—Thoroughwort, Boneset, Indian sage, E.; *Herbe d'eupatoire perfoliée*, *Herbe à fièvre*, *Herbe parfaite*, Fr.; *Durchwuchsdost*, *Durchwuchsenener Wasserdost*, G.

The leaves and flowering tops of *Eupatorium perfoliatum*, *Linné*, s. *E. connatum*, *Michaux*, gathered after flowering has commenced. Bentley and Trimen, *Med. Plants*, 147. *Nat. Ord.*—Compositæ, Eupatoriæ.

Description.—Thoroughwort inhabits damp soil and low swampy grounds in Canada and the United States. It is a hairy perennial, with an erect stout stem 2 to 4 feet (0.6 to 1.2 M.) high and much branched at the summit; the leaves are opposite, tapering, lanceolate, 4 to 6 inches (10 to 15 Cm.) long, united at the base, with the margin crenately serrate, rugosely veined, rough above and minutely resinous dotted beneath. The flowers are in dense level-topped corymbs; the heads have an oblong involucre consisting of lance-linear scales, and contain ten to fifteen tubular white florets with a bristly pappus in a single row. Its flowers appear in July, and it continues to bloom until September. The leaves and the flowering tops with the small branches are collected in July; on drying, they lose from 75 to 80 per cent. in weight. The drug has a rather weak aromatic odor and a somewhat astringent and persistently bitter taste.

Constituents.—Boneset contains a minute quantity of volatile oil, some tannin, and a bitter principle which has not been isolated. The analyses of W. Peterson (1851) and M. H. Bickley (1854) elicited, besides those mentioned, the usual common constituents of herbs. G. Latin (1880) isolated from the ethereal extract, by means of benzin, white needles of a tasteless wax, and ascertained the bitter principle *eupatorin* to be a glucoside soluble in alcohol, chloroform, ether, and boiling water; boiled with sulphuric acid and water, it gives off a raspberry-like odor. Parsons (1879) determined in the air-dry herb 13.5 albuminoids, 15.2 resin and chlorophyll, and 7.5 ash.

Off. Prep.—Extract eupatorii fluid., U. S.

INFUSUM EUPATORII.—Infusion of thoroughwort, E.; *Tisane d'herbe à fièvre*, Fr.; *Eupatorium-Aufguss*, G.—Take of thoroughwort a troyounce; boiling water a pint. Macerate for 2 hours in a covered vessel, and strain.—U. S. P. 1870.

Allied Species.—Most of the numerous species of *Eupatorium* and of some allied genera appear to possess similar properties, and are occasionally employed in regular or domestic practice. The following may be mentioned:

EUP. TENUFOLIUM, *Willdenow*, s. *E. verbenæfolium*, *Michaux*, s. *E. pubescens*, *Persoon*, grows from Massachusetts to Louisiana, and is characterized by lance- or oblong-ovate leaves, which are truncate below, coarsely toothed toward the base, and are alternate on the branches. It is popularly known as *wild horehound*, like the nearly-allied *Eup. rotundifolium*, *Linné*, which is

found in similar localities, and is mainly distinguished by its roundish-ovate and slightly heart-shaped leaves.

E. FENICULACEUM, *Willdenow*, called *dog-fennel*, is a common weed in fields and damp places from Virginia to Florida, with the leaves pinnately dissected into filiform segments. The juice is used for relieving pain from the bites of insects.

E. INCARNATUM, *Walter*, of the Southern United States from Texas to North Carolina, has triangular ovate, long-petioled leaves, and is used in Texas under the name of *mata* for flavoring tobacco.

E. PURPUREUM, *Linné*, is common in low grounds, with a tall, simple, purplish-colored or spotted stem, ovate or lanceolate-petiolate leaves in whorls of three to six, and dense corymbs of mostly purplish flowers. It is known as *trumpet-weed* and *gravel-root*, the rhizome and rootlets being popularly used in various ailments of the urinary organs. The rhizome contains a yellow crystallizable principle which gives a dark-green color with ferric chloride; it is probably *quercitrin*.

E. CANNABINUM, *Linné*.—Water-hemp, *E.*; Eupatoire d'Avicenne. Origan aquatique, *Fr.*; Wasserhanf, *G.*—It is indigenous to Europe; the leaves resemble hemp-leaves, but are mostly trifoliate; the root and leaves have diuretic, and in larger doses emetic, properties. *Righini* states that the leaves and flowers contain a white bitter alkaloid soluble in ether; the sulphate is said to crystallize in silky needles.

E. AYAPANA, *Ventenat*, of Brazil, has short-stalked, lanceolate, hairy, and almost entire leaves with purplish veins and a coumarin-like odor. It is an aromatic tonic.

MIKANIA GUACO, *Humboldt et Bonpland*, a native of Colombia and the West Indies, is an aromatic, bitter climbing herb 20 feet (6 M.) long, with the leaves ovate-elliptic and rusty tomentose beneath; it was at one time highly lauded as a remedy in cholera and in hydrophobia; in its native country it is reputed to be an antidote to the poison of serpents, like the Brazilian *Mik. opifera*, *Martius*, which is called *erva da cobra*. Their medicinal properties are probably not superior to those of *Mik. scandens*, *Linné*, of the United States, which has nearly triangular heart-shaped leaves. The genus *Mikania* is closely allied to *Eupatorium*, not only botanically, but also in its sensible properties.

Medical Action and Uses.—*Eupatorium* resembles chamomile in its effects. It is a stimulant tonic in small and a laxative in large doses, and an emetic or diaphoretic in warm infusion. Like all such plants, it is used to prevent or to break the chill in *intermittent fever* of a mild type. A hot infusion is a popular and efficient remedy in the forming stage of *muscular rheumatism*, *sore throat*, *bronchitis*, and even *influenza*. Its power of relieving pain in the limbs in the last-named disease entitled it to the popular name of "boneset." In atonic *dyspepsia* its effects resemble those of other bitter tonics. The *dose* of the powder is stated to be 20 or 30 grains (Gm. 1.30–2.00). The infusion, which is the most convenient form for administering the medicine, is made with 1 ounce of the herb to a pint of boiling water, macerated for 2 hours in a covered vessel and strained. *Dose* as a tonic, 1 or 2 fluidounces.

Mikania guaco was first known (1788) medicinally as an antidote to serpents' bites used in South America, and about 1831 it had a reputation in Europe for the cure of dyspepsia, debility, asthma, gout, rheumatism, and even cholera! It is therefore probably a stimulant tonic (*Strumpf, Handbuch*, ii. 14). More recently (1879) it was proposed as a cure for cancer.

Of the other allied species mentioned above, the greater number appear to possess essentially the same properties as the official plant, but *E. purpureum* and *E. cannabinum* are believed to be diuretic.

EUPHORBIA.—SPURGE.

Wild ipecac, *Wild hippo*, *E.*; *Euphorbe*, *Fr.*; *Wolfsmilch*, *G.*

The roots of two plants of this genus were recognized by the U. S. P. previous to 1880—namely, *Euphorbia corollata*, *Linné* (*Meehan, Native Flowers*, i. 109), and *Euph. Ipecacuanha*, *Linné*.

Nat. Ord.—Euphorbiaceæ.

Origin.—*EUPH. COROLLATA*, the *blooming* or *large-flowering spurge*, also called *snake-milk* and *milk purslain*, is a smooth perennial herb which is met with in low, sandy, and dry soil from Canada to Florida and west to Mississippi, and is abundant in many localities, chiefly of the Southern and Western States. It produces a slender, nearly simple stem 2 to 3 feet (60 to 90 Cm.) high, which has the leaves, excepting the floral ones, alternate, linear-oblong, and obtuse. The flowers are in umbels of five to seven rays, each one being again two- or three-forked, and are conspicuous for the showy white appendages to the involucre, which have the appearance of petals and bear a greenish gland at the base. The smooth capsule separates at maturity into three carpels,

each containing a single ash-colored seed. It flowers in the latter part of summer and in autumn, when the root should be collected. This, like the next, is rarely met with in the market; we have received instead of it the roots of *Gillenia stipulacea*, of *Triosteum perfoliatum*, and of other plants.

EUPH. IPECACUANHA, called *ipecac spurge* and *American, Carolina, or white ipecac*, is a smooth perennial herb of a dark-green or dark-purplish color, growing in barren, sandy soil at a limited distance from the seashore from Connecticut southward to Georgia. It produces several ascending or often diffusely-spreading stems, which fork from near the base and have opposite, obovate or oblong, obtuse, and entire, nearly sessile leaves. The flowers are inconspicuous, long-peduncled, and appear singly from the forks or the axils of the upper leaves. The nearly smooth capsule contains in each of its three cells one white somewhat dotted seed. It flowers during the spring months.

Description.—The root of the *blooming spurge* is $1\frac{1}{2}$ to 2 feet (45 to 60 Cm.) long, and, when full grown, about an inch (25 Mm.) thick, cylindrical, and little branched; is externally of a dark-brown or, when old, of a blackish, color; has underneath the thin corky layer a thickish white bark, which encloses a spongy, porous, whitish wood, radially striate by many medullary rays. In the dry state it is longitudinally wrinkled and breaks with a short nearly smooth fracture. It is inodorous and has a sweetish afterward warm taste.

The root of the *ipecac spurge* resembles the preceding in general characters, but is thinner, from 3 to 6 feet (0.9 to 1.8 M.) long, has externally a gray or brownish-yellow corky layer, which is never blackish or dark colored, and shows internally a yellowish porous wood. Odor and taste are similar to the preceding. Barton believed it to be equally efficacious throughout the year.

Constituents.—The latest analyses of the last-named root, by Petzelt (1873) and Dilg (1875), agree with the older one of Bigelow in proving the presence of resinous, gummy, and other common constituents of plants; they also showed abundant presence of starch. Petzelt regards the resinous portions as containing the emetic principle. The root may possibly contain a glucoside, since Dilg did not get a reaction for glucose until the decoction had been boiled with an acid. *Euphorbon* was found among the products extracted by petroleum benzin. The constituents of blooming spurge-root are probably similar.

Allied Plants.—The genus *Euphorbia* comprises a large number of shrubby and herbaceous species, all of which are laticiferous and possess more or less acrid properties. Of the thirty or more species growing in the United States, we give brief descriptions of a few which are low or prostrate:

EUPHORBIA PROSTRATA, *Aiton*. It is villous-pulverulent, with roundish, very obtuse, and above serrulate leaves, and produces a woolly fruit with quadrangular, rugose, and brown seeds. It grows in moist localities in the Southern States.

EUPH. MACULATA, *Linné*. It is a common weed, growing on roadsides, with oblong or nearly linear leaves, having usually a brownish spot upon the upper surface, and being very oblique at the base and serrulate above. Like the following species, it is known in some places as *spotted eyebright*:

EUPH. HUMISTRATA, *Engelmann*. It inhabits rich soil in the Mississippi Valley, and resembles the two preceding, but has elliptical or obovate leaves and obtusely-angled seeds.

EUPH. HYPERICIFOLIA, *Linné*. It is found in the West Indies, and is common in the United States and Canada, grows to the height of 15 or 20 inches (38 to 50 Cm.), resembles in foliage the preceding, and has smooth capsules and obtusely-angled seeds.

These and allied species probably contain the same principles found by Zollikofer (1842) in *E. maculata*—namely, caoutchouc, resin, tannin, gallic acid (?), etc. Similar constituents have been found by John, Stickel, and others in *E. Cyparissias*, *Linné*, *E. Esula*, *Linné*, *E. Peplus*, *Linné*, *E. helioscopia*, *Linné*, and others which are natives of Europe, but occasionally met with in cultivation or spontaneous in North America. Their acrid principle has not been fully isolated. Numerous other species of *Euphorbia* are medicinally employed in those countries where they are indigenous. Recently, *Euph. pilulifera*, *Linné*, an herbaceous plant of India and Australia, has been recommended in bronchial and asthmatic affections.

Medical Action and Uses.—Large-flowering spurge is reputed to possess emetocathartic properties, and its bruised root will vesicate the skin. Hence it cannot be a safe agent in cases of gastro-intestinal irritation. *Dose* as an emetic, 20 grains (Gm. 1.30); as a cathartic, 10 grains (Gm. 60); as a diaphoretic, 5 grains (Gm. 0.30).

Ipecacuanha spurge does not differ essentially from the other officinal species of *Euphorbium*. It may be used under the same conditions and in similar doses.

A case of poisoning by the seeds of *Euphorbia latas*, found in the neighborhood of Philadelphia, is related by Harlan (*Med. and Physical Researches*, p. 603). The symp-

toms included violent retching and vomiting, with excessive purging, followed by stupor and dilated pupils. The patient recovered after cold affusions. A similar case of poisoning by the seeds of *E. lathyris* is reported in a French journal for 1881 (*Bull. de thérap.*, ci. 541). The reporter recommends opiates as the most appropriate antidote.

EUPHORBIA PROSTRATA was in 1861 reported by Dr. Irwin, Asst. Surgeon U. S. A., to be esteemed by the Indians and settlers in Arizona as an infallible remedy for the bite of the rattlesnake and for the bites and stings of almost all venomous animals and insects. In several experiments performed by him on dogs allowed to be bitten by rattlesnakes, and after the characteristic effects of the venom had been fully developed, the fresh juice of this plant was applied to the wounds, and at the same time administered internally in doses of from 4 to 6 ounces, with the effect of immediately abating the symptoms and afterward curing the animals.

EUPHORBIIUM, *P. G.*—EUPHORBIIUM.

Euphorbe, Gomme-résine d'euphorbe, Fr.; Euphorbium, G.

The gum-resin obtained from *Euphorbia resinifera, Berg.* Bentley and Trimen, *Med. Plants*, 240.

Nat. Ord.—Euphorbiaceæ.

Origin.—The plant is indigenous to the lower slopes of the Atlas Mountains of Morocco. It has an ascending, cactus-like, fleshy, quadrangular stem with spreading branches, and, instead of leaves, is furnished with divergent, spinescent stipules, situated in pairs on the angles; the flowers are in pedunculate cymes of three or rarely more. On wounding the branches a milk-juice exudes, which hardens upon the plant, usually encrusting the spines. While it is being collected the mouth and nostrils are protected by a cloth from the irritating effects of the dust.

Description.—Euphorbium is seen in roundish or somewhat three-cornered, conical-cylindrical, or irregular pieces varying considerably in size, the largest measuring nearly an inch (25 Mm.). The shape is influenced by the portion of the plant around which the exudation is hardened, and most pieces are observed with one or more holes and enclosing fragments of the spines, flowers, or fruit. Euphorbium is light brownish-yellow, scarcely glossy, somewhat translucent, brittle, nearly inodorous, but the dust excites violent sneezing, and, if inhaled, acts as an acrid poison. The taste is at first slight, afterward burning and acrid. When heated it gives off a faint odor, suggesting that of benzoin, and afterward fuses and burns with a bright, sooty flame. Euphorbium is not entirely soluble in any of the simple solvents, and when triturated with water yields a turbid mixture, but not an emulsion.

Constituents.—The older analyses by Braconnot, Brandes, and others seem to indicate that the composition of euphorbium varies to some extent; the *resin*, readily soluble in cold alcohol and possessing an extremely burning taste, varied between 37 and 44 per cent.; Flückiger (1868) obtained 38 per cent. of it, and Hlasiwetz (1867) ascertained its composition to be $C_{10}H_{16}O_2$. This resin is amorphous, imparts to boiling water its acrid and bitter taste, and, according to Sommer (1859), does not yield umbelliferon. The sparingly soluble, crystallizable resin of Bonastre and others was named *euphorbon* by Flückiger, who obtained 22 per cent. and gave it the formula $C_{13}H_{22}O$. It is soluble in ether, benzol, benzin, amylic alcohol, chloroform, acetone, glacial acetic acid, and hot alcohol, but requires about 60 parts of alcohol for solution at the ordinary temperature. When the last traces of the acrid resin have been destroyed by boiling in a weak solution of potassium permanganate it is entirely tasteless. If its alcoholic solution is allowed to evaporate until it forms a thin film, and this is moistened with sulphuric acid, the slow addition of a little strong nitric acid produces a fine violet color—a reaction which is also observed with lactucerin. Braconnot (1808) observed the presence of malic acid in euphorbium. Flückiger obtained 12 per cent. of *malates*, chiefly of calcium and sodium, 10 per cent. of *mineral compounds*, and 18 per cent. of *gum*, which is precipitated by acetate of lead, also by silicate of sodium and borax.

Pharmaceutical Uses.—Euphorbium is an ingredient in a few plasters. *TINCTURA EUPHORBII* is made with 1 part of euphorbium and 10 parts of alcohol.

Physiological Action.—The extremely acrid qualities of euphorbium were known to the ancients, for both Pliny and Dioscorides describe the mode of collecting the juice so as to prevent its irritating emanations from affecting the face or hands. They also speak of its taste as persistently hot and acrid, drying the throat. Its dry powder does not affect the sound skin usually, but it irritates the mucous membranes, and causes the

eyes to weep and grow red, the nose to run with watery and even bloody mucus, and saliva to flow abundantly from the mouth. To prevent these effects, says Pereira, some drug-grinders employ masks with glass eyes, others apply a wet sponge to the nose and face, while others cover the face with crape. Individuals who have been exposed for some time to the influence of this dust suffer with headache, giddiness, and ultimately become delirious. I was informed, he adds, of an Irish laborer who was made temporarily insane by it, and who during the fit insisted on saying his prayers at the tail of the mill-horse. In a case which fell under his notice a man grew suddenly delirious, and presently became insensible and fell in a fit. His face was red and swollen, his pulse frequent and full, and his skin very hot. On being bled his consciousness returned and he complained of great headache. Internally, it causes great thirst, dryness of the throat, colic, vomiting, and purging, and in excessive doses, besides these symptoms, cold sweats, syncope, thready pulse, and even inflammation and gangrene of the bowels.

Medical Uses.—Although euphorbium was anciently and even in comparatively modern times used as a drastic purgative in *dropsy*, yet the extreme harshness of its operation led to its being associated with milder drugs for the same purpose, and at the present day it is never given internally. It was also at one time applied as a local stimulant in certain cases of *paralysis*, and more recently as a *sternutatory* when mitigated with inert or mild powders. As a local irritant it has been used in the same cases for which mezerion is appropriate, and particularly in plasters intended to prolong *suppuration*, as in cases of obstinate *sciatica*. In ointments it was applied to *ulcers* maintained by necrosed bone. Plasters containing it have also been employed in the treatment of chronic swellings of the *joints* induced by scrofula, gout, or rheumatism.

EUPHRASIA.—EYEBRIGHT.

Euphrasia, Fr.; *Augentrost*, G.

Euphrasia officinalis, Linné.

Nat. Ord.—Scrophulariaceæ.

Description.—An annual plant about 6 inches (15 Cm.) high, indigenous to the greater part of Europe, and in North America to the White Mountains and from the Great Lakes northward. It has opposite, shortly petiolate or sessile, ovate or lanceolate leaves, which are about $\frac{1}{4}$ inch (8 Mm.) long, and have four or five teeth on each side; the upper (floral) leaves are alternate, nearly rhomboid, and bristly-toothed. The axillary flowers have a four-cleft calyx and a white or lilac two-lipped corolla with a yellow throat, four ascending stamens, and an oblong, many-ovuled ovary. When fresh, the plant has a faint balsamic odor which is almost completely lost on drying; the taste is somewhat saline, bitter, and scarcely astringent.

Constituents.—Examined by J. B. Enz (1859), the fresh plant was found to contain 62 per cent. of moisture and 10.8 per cent. of cellulose, the remainder being tannin, a little volatile oil, an acrid and bitter principle, several organic acids, mannit, glucose, and other common principles. The tannin precipitates ferric salts dark-green, and lead salts of a bright-green, color.

Medical Action and Uses.—The name “euphrasia,” signifying cheerfulness, was anciently as well as in more recent times given to this plant, which was supposed to render the vision clearer and to cure various inflammatory affections of the eyes. Its English name, *eyebright*, may be due to this circumstance, but some maintain that its use in such disorders was prompted by the doctrine of signatures, for a yellow spot upon its flower suggests the pupil of the eye. Its utility, when applied as a fomentation or decoction in *ophthalmia*, was probably due to its astringency. A vinous decoction of it was esteemed in *toothache*; a closely-allied species, also used for this affection, was for that reason called *odontitis*. Internally, eyebright was also given, as a distilled water or a tincture, for *chronic catarrhs*.

EXTRACTA ET EXTRACTA FLUIDA.—EXTRACTS AND FLUID OR LIQUID EXTRACTS.

Extraits et Extraits liquides, Fr.; *Extrakte und Flüssige Extrakte*, G.

Extracts are preparations which are obtained by removing from crude drugs a solution of their medicinal principles and evaporating it to the consistence of a soft solid or to dryness. The medicinal principles may be removed either by expressing the crude drugs

while fresh and juicy or by exhausting the dried and powdered drugs with water, alcohol and water, alcohol, or ether, whereby the *inspissated juices* or the *aqueous, hydro-alcoholic, alcoholic, or ethereal extracts* are obtained; the latter contain all the fixed and volatile oils, together with resin, which may have been contained in the drug, and usually remain liquid after the solvent has been completely evaporated; for which reasons the Pharmacopœia has separated them as *OLEORESINÆ* (which see).

INSPISSATED JUICES.—The United States Pharmacopœia has admitted only one inspissated juice (*Ext. taraxaci*), while those of the narcotic herbs which are not indigenous or grow spontaneously only in a few localities have very properly been dismissed. The expressed juices of herbs contain, besides the medicinal principles, chlorophyll in suspension and albuminous and mucilaginous matters in solution. Of these the chlorophyll separates on heating the liquid to about 55° C. (130° F.); the albuminoids are coagulated on this temperature and about 94° C. (200° F.), and the solubility of the gum and mucilage is not affected by heat; but these principles may be removed by alcohol, in which they are insoluble. The different pharmacopœias have adopted different processes for the purification of the expressed juices: that of Germany endeavors to obtain the extracts as free as possible from inert principles, and purifies by heat and by alcohol, as recommended by C. F. Mohr (*Pharmacopœia universalis*, 1845); the French Codex, like the former U. S. P., directs the juice to be coagulated by heat, but the gum is not precipitated; and that of Great Britain aims only at the separation of the albumen, and reincorporates with the extract the previously-removed chlorophyll. The inspissated juices of the latter are of a green color and of a firm pilular consistence; those of the other pharmacopœias are brown in color, and cannot be made into pills without the addition of some vegetable powder. Provided the material has been of the same quality, an inspissated juice made according to the German Pharmacopœia ought to be stronger, and if made by the British Pharmacopœia weaker, than is obtainable by the French (and former United States) process.

To obtain the juice, the vegetable should have been recently collected, well washed with water to free it from extraneous matter, and the superfluous water drained off. It is then cut into pieces of convenient size and bruised in a stone mortar, by means of a pestle made of hard wood, until reduced to a smooth pulpy mass. If not succulent enough, a little water may be sprinkled over it during this operation. The mass is then enclosed in canvas bags, strongly expressed, again mixed with water, and expressed a second time, whereby that portion of the juice remaining in the pulp is obtained. The mixed liquids are then heated to 80° C. (176° F.) to coagulate the albumen, which encloses also the chlorophyll, and is removed by straining, after which the clear liquid is evaporated to the proper consistence (*F. Cod.*). The German Pharmacopœia directs the strained liquor to be evaporated until reduced in weight to 10 per cent. of the weight of the plant, when an equal weight of alcohol is added to precipitate gummy matter; the mixture is set aside until the insoluble matter has subsided; it is then decanted and filtered, and the retained liquid obtained by the addition of a little diluted alcohol; the alcohol is partly distilled off and the remaining liquor evaporated as before. The British Pharmacopœia directs the heating of the expressed juice to 130° F., whereby the chlorophyll separates from the liquid and is collected upon a calico strainer. The strained liquor is now heated to 200° F. to coagulate the albumen, again strained, and evaporated to the consistence of a thin syrup, to which the chlorophyll, previously separated, is added and well mixed by assiduous stirring. Evaporation to the proper consistence will complete the extract. If the part of the plant employed does not contain chlorophyll, its removal and subsequent readmixture are obviously omitted from the process, and if starch is present some of it will pass through the press-cloth, and the expressed juice must be allowed to subside and then be decanted from the deposited fecula. The U. S. process for extract of *taraxacum* is faulty in not removing the albumen.

AQUEOUS EXTRACTS were formerly usually made by boiling the drug with water, expressing the watery solution, and evaporating. The pharmacopœias have very properly discontinued this process almost altogether, and have in nearly all cases substituted infusion or percolation with water. Prolonged boiling with water will often render inert constituents (starch, etc.) soluble in water, and thus increase the amount of extract, to the injury of its quality. In other cases, however, it may not only injure the quality, but also decrease the yield of the extract, as in the case of *krameria*, the tannin of which is either partly destroyed or becomes insoluble through combination with other constituents. Some pharmacopœias exhaust the comminuted drugs by hot infusion or digestion, but cold infusion or percolation appears to produce not only unobjectionable aqueous extracts,

but they are in some cases at least superior in appearance to those made by hot infusion or digestion. When infusion is directed, the properly-comminuted drug is mixed with sufficient water to cover it, and in case the material be light, it is submerged by putting a perforated cover with sufficient weights upon it to keep it covered by the water. After due maceration or digestion a concentrated solution of the principles is at once obtained by expression, and a second maceration with a small amount of water and expression will practically exhaust the drug. If a large quantity of water be used in the beginning, a second maceration may be avoided or becomes unprofitable, but a longer-continued evaporation is necessary.

Only two extracts are prepared with water containing acetic acid or ammonia, which chemicals are ordered in a fixed proportion to the drug, the extraction being finished with water, used merely for the purpose of recovering a percolate equal to the amount of menstruum first employed. (For the proper treatment of the material by displacing with an aqueous menstruum we refer to the remarks on PERCOLATION.) The menstruum used is—

Water for Aloe, Gentiana, Hæmatoxylon, Krameria, Maltum, Opium, Quassia ;

Water and acetic acid for Colchici radix ; and

Water and ammonia for Glycyrrhiza.

ALCOHOLIC EXTRACTS.—Whether made with strong or diluted alcohol, the powdered material is most conveniently exhausted by percolation. In all cases where alcohol or diluted alcohol is directed in the beginning, the same menstruum is now ordered until exhaustion is accomplished. But for some extracts a stronger and a diluted alcohol are directed : in such cases the former is always used first, and by the addition of the latter an amount of percolate obtained equal in weight to that of the stronger alcohol employed, and usually more than sufficient to practically exhaust the drug. It is obvious that the tinctures obtained in this manner must be of uniform alcoholic strength from beginning to end ; which is a decided improvement as compared with a number of processes of the old Pharmacopœia. This uniformity of the menstruum of the percolate renders a separate treatment of different fractions unnecessary ; the alcohol is distilled off from the whole of the tincture, and the residue left is then evaporated to the proper consistence. Yet for several extracts it has been deemed proper to distil or evaporate only the weak tincture, and after mixing the residue with the percolate first obtained—rather less than one-third of the whole amount—to evaporate to the proper consistence. Such a precaution is particularly commendable for physostigma, but scarcely necessary for mezereum. Spontaneous evaporation of the most concentrated portion of the percolate has been retained only for rhubarb. Only one extract, ergot, is directed to be made from the fluid extract, yet when the processes for several other extracts and the corresponding fluid extracts are examined, there would appear to be as little objection to prepare the former from the latter as with the important preparation mentioned.

The menstruum used for this class of extracts, as a rule, has been judiciously selected, and leaves but little occasion for criticism :

Alcohol for Aconitum (with tartaric acid), Cannabis indica, Juglans, Mezereum, Physostigma ;

Alcohol 8 parts, water 1 part, for Nux vomica ;

Alcohol 3 parts, water 1 part, for Cinchona, Iris, Podophyllum, Rheum ;

Alcohol 2 parts, water 1 part, for Belladonnæ folia, Digitalis, Hyoscyamus, Leptandra ;

Diluted alcohol for Arnice radix, Colocynthis, Conium (with hydrochloric acid), Euonymus, Stramonii semen ;

Alcohol 3 parts, water 4 parts, for Ergota (with hydrochloric acid).

ETHEREAL EXTRACTS.—All the ethereal extracts of the United States Pharmacopœia will be found under **OLEORESINE**, where also the necessary apparatuses and operations are described. *Ext. mezerei æthereum*, *Br. P.*, is the ethereal extract of an alcoholic extract, the latter being prepared from the drug and afterward exhausted by ether.

Fluid or Liquid Extracts, in the meaning of the United States and British Pharmacopœias, are permanent concentrated solutions of vegetable drugs, made of such a strength that, in the United States, 1 Ccm. contains the medicinal principles and represents the virtues of 1 Gm. of the drug. Formerly the pharmacopœial strength was 1 troyounce of drug to 1 fluidounce of the fluid extract. The present Pharmacopœia has decreased the strength about 5 per cent., and based it upon the relation of the metric measures of weight and capacity, so that any weight of a given drug is to be converted into a fluid extract having the bulk of the same weight of water at its maximum density ; or, in other words, a Gm. of the drug is to be represented by 1 Ccm. of the fluid extract. The Pharmacopœia omits to state the temperature at which the finished preparation is to be

measured; it is obvious, however, that the fluid extract should in all cases be cooled and measured at or near 15° C. (59° F.), which is the standard temperature adopted for taking specific gravity. The relation of the former and present fluid extracts is shown at a glance by the following table:

100 troyounces of drug yield 2952.4 Cem. or 100 f̄ U. S. 1870: 3110.3 Cem. = 105.25 f̄ U. S. 1880.									
100 ounces av. “ “ 2691.1 “ 91.15 “ “ 2834.9 “ = 95.94 “ “									
100 Gm. “ “ 95.15 “ 3.22 “ “ 100.0 “ = 3.38 “ “									

It will be observed that 100 ounces avoirdupois of a drug will practically make 6 pints or 96 fluidounces of fluid extract, the actual difference as compared with the pharmacopœial requirements being about half a fluidrachm; or for 20 fluidounces of the present fluid extracts only 19 troyounces, not 20 (as heretofore), of drug will be required.

The liquid extracts of former pharmacopœias of Continental Europe, which are still occasionally described under their older official title, *Mellago*, were solutions of extracts in water, made in proportions of 3, or sometimes 2, parts of the former to 1 of the latter; they can be kept unaltered for a short time only, and are best prepared extemporaneously. The liquid extracts of the British Pharmacopœia vary in relative strength: 1 fluidounce (Imperial measure) of some represents 1 avoirdupois ounce of the drug, of another 2 ounces, and different proportions in the remainder.

All the pharmacopœial fluid extracts are directed to be prepared by percolation, and, as with the extracts, a menstruum uniform in alcoholic strength is employed during the process of exhaustion. This statement requires to be qualified in this, that when glycerin is used with the first portion of the menstruum percolation is continued and finished with the same alcoholic liquid, but not mixed with glycerin. The only exception to this rule is cinchona, the percolation of which is commenced with a mixture of glycerin 1 and alcohol 3 parts, and is finished with a mixture of water 1 and alcohol 3 parts. As has been customary for these preparations, a portion of the strongest percolate is reserved; but while the weaker percolate was heretofore concentrated to a given volume, which, added to the reserved portion, would produce the required measure of fluid extract, it is now directed to be evaporated to a soft extract, which is dissolved in the reserved portion, the requisite measure being made up with the initial menstruum containing no glycerin. On the concentration of an alcoholic tincture the residue left will always have a more aqueous menstruum, and on adding such to the reserved portion the alcoholic strength of the whole menstruum is necessarily weakened, causing disturbance in the solvent power and more or less precipitation of some of the principles originally held in solution. By evaporating the weak tincture to a soft extract most of the water is also expelled, and the comparatively small portion remaining with the extract will occasion but a slight change in the menstruum of the reserved portion, this menstruum being at the same time the most suitable for dissolving the extractive matter, and its alcoholic strength being not changed by the subsequent addition of some of the original menstruum. Special authority is given by the Pharmacopœia to employ, where it may be applicable, the process of re-percolation, described below, without change of the initial menstruum.

An unusually large number of critical experiments were performed for use in the last Pharmacopœia revision, many being embodied in the three reports on fluid extracts made by Prof. Diehl to the American Pharmaceutical Association. (See *Proceedings A. P. A.*, 1878-80). The selection of the most suitable menstruum was thereby greatly facilitated, and the changes which may become necessary after practical experience during several years will probably be few and unimportant. The practicability of the menstruum used for each pharmacopœial fluid extract has been discussed by Mr. Alonzo Robbins in a series of papers (see *Amer. Jour. Phar.*, 1883), giving his observations with fluid extracts especially prepared for this purpose and kept on hand for over three years. When it is considered that the material from which fluid extracts are prepared is not anhydrous, but merely air-dry: that in the manipulation a partial though slight evaporation of alcohol takes place: that in percolating each subsequent portion of the tincture has a more or less different composition from the preceding one; and that the alcoholic strength of the menstruum is finally somewhat, though slightly, changed,—there must be abundant cause for deposition occurring in these preparations, which, together with the influence of changes in temperature and other causes, has been fully discussed in elaborate papers by Prof. J. U. Lloyd in *Proc. Amer. Phar. Assoc.*, 1881-82.

For the pharmacopœial extract and fluid extract of the same drug the menstruum is usually alike. For cinchona, glycerin has in part replaced the water to ensure the greater

permanence of the liquid preparation; for gentian and quassia an alcoholic menstruum instead of water was necessary to prevent fermentation; and for digitalis, hyoseyamus, and stramonium an increased strength of alcohol has been selected, perhaps for insufficient reasons, at least as far as the two last-named drugs are concerned. The menstruum for exhausting the drugs is as follows:

Alcohol for Aconitum, Pulvis aromaticus, Belladonnæ radix, Brayera, Calamus, Cannabis indica, Capsicum, Cimicifuga, Cubeba, Cypripedium, Eucalyptus, Gelsemium, Ipecacuanha (special process), Lupulinum, Mezereum, Sabina, Sanguinaria, Scilla, Veratrum viride, Xanthoxylum, Zingiber;

Alcohol 8 parts, water 1 part, for Nux vomica;

Alcohol 3 parts, water 1 part, for Digitalis, Grindelia, Guarana, Hydrastis, Hyoseyamus, Iris, Podophyllum, Rheum, Serpentaria, Stramonii semen;

Alcohol 2 parts, water 1 part, for Buchu, Colchici radix, Colchici semen, Senega (special process), Valeriana, Viburnum;

Diluted alcohol for Arnicæ radix, Calumba, Conium (special process), Dulcamara, Erythroxylon, Eupatorium, Gentiana, Glycyrrhiza (special process), Lobelia, Pilocarpus, Quassia, Rumex, Spigelia, Stillingia;

Alcohol 3 parts, water 4 parts, for Ergota (special process), Senna;

Alcohol 2 parts, water 3 parts, for Taraxacum;

Alcohol 1 part, water 2 parts, for Aurantii amari cortex, Frangula, Hamamelis, Scutellaria;

Alcohol 1 part, water 3 parts, for Lactucarium (special process);

Alcohol 13 parts, glycerin 7 parts, followed by alcohol, for Gossypii radix;

Alcohol 3 parts, glycerin 1 part, then alcohol 3 parts, water 1 part, for Cinchona flava;

Alcohol 15 parts, water 5 parts, glycerin 2 parts, for Matico;

Alcohol 9 parts, water 7 parts, glycerin 4 parts, for Rubus;

Diluted alcohol 9 parts, glycerin 1 part, for Chimaphila, Chirata, Geranium, Rhus glabra, Rosa gallica, Uva ursi;

Diluted alcohol 17 parts, glycerin 3 parts, for Leptandra;

Diluted alcohol 4 parts, glycerin 1 part, for Cornus, Krameria, Pareira;

Alcohol 3 parts, water 6 parts, glycerin 1 part, for Sarsaparilla (two fluid extracts);

Water 2 parts, glycerin 1 part, afterward diluted alcohol, for Prunus virginiana;

Boiling water for Castanea, Triticum (both fluid extracts contain about 20 per cent. by measure of alcohol).

Infusion is better adapted than percolation for exhausting the two drugs last mentioned.

Preparation.—FINENESS OF POWDER. (For remarks on powdering consult the article PULVERES.) The fineness of powder is expressed in the Pharmacopœia either by descriptive words (generally so in the case of brittle or easily pulverizable substances) or in terms expressing the number of meshes to a linear inch in the sieve. These different forms of expression correspond to each other as follows:

A <i>very fine</i> powder	{ should pass through a sieve having 80 or more meshes to the linear inch. }	= No. 80 powder.
A <i>fine</i> powder	{ should pass through a sieve having 60 meshes to the linear inch. }	= No. 60 powder.
A <i>moderately fine</i> powder	{ should pass through a sieve having 50 meshes to the linear inch. }	= No. 50 powder.
A <i>moderately coarse</i> powder	{ should pass through a sieve having 40 meshes to the linear inch. }	= No. 40 powder.
A <i>coarse</i> powder	{ should pass through a sieve having 20 meshes to the linear inch. }	= No. 20 powder.

"In certain cases powders of a different degree of fineness (*e. g.* No. 30, No. 12) are directed to be taken. When a substance is directed to be in a limited degree of fineness, as specified by the number of meshes to the linear inch in the sieve, not more than a small (indefinite?) proportion of the powder should be able to pass through a sieve having ten meshes more to the linear inch."—*U. S.*

PERCOLATION.—"The process of percolation or displacement directed in the Pharmacopœia consists in subjecting a substance or substances, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of menstruum in such a manner that the liquid, as it traverses the powder in its descent to the recipient, shall be

charged with the soluble portion of it, and pass from the percolator free from insoluble matter. When the process is successfully conducted, the first portion of the liquid or percolate passing through the percolator will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion will be destitute of color, odor, and taste other than those possessed by the menstruum itself.

“The percolator most suitable for the quantities contemplated by the Pharmacopœia should be nearly cylindrical or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become narrower toward the orifice, so that a perforated cork bearing a short glass tube may be tightly wedged into it from within until the end of the cork is flush with its outer edge. The glass tube, which must not protrude above the inner surface of the cork, should extend from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches (3 to 4 Cm.) beyond the outer surface of the cork, and should be provided with a closely-fitting rubber tube at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding it in position. The dimensions of such a percolator, conveniently holding 500 Gm. of powdered material, are preferably the following: Length of body, 14 inches (36 Cm.); length of neck, 2 inches (5 Cm.); internal diameter at top, 4 inches (10 Cm.); internal diameter at beginning of funnel-shaped end, $2\frac{1}{2}$ inches ($6\frac{1}{2}$ Cm.); internal diameter of the neck, $\frac{1}{2}$ inch (12 Mm.), gradually reduced at the end to $\frac{2}{3}$ of an inch (1 Cm.). It is best constructed of glass, but, unless otherwise directed, may be constructed of a different material. The percolator is prepared for percolation by gently pressing a small tuft of cotton into the space of the neck above the cork, and a small layer of clean and dry sand is then poured upon the surface of the cotton to hold it in place.

“The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and it is thoroughly stirred with a spatula or other suitable instrument until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders and those that are finer requiring a No. 20 sieve, whilst No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from it into the percolator. It is then shaken down lightly, and allowed to remain in that condition for a period varying from 15 minutes to several hours, unless otherwise directed, after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately-fitting disk of filtering-paper or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions are accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached in this the height corresponding to its level in the percolator, which is now closely covered to prevent evaporation, and the apparatus allowed to stand at rest for the time specified in the formula.

“To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated if the percolate is to be measured, or of a tared bottle if the percolate is to be weighed; and by raising or lowering this recipient the rapidity of percolation may be increased or lessened as may be desirable, observing, however that the rate of percolation, unless the quantity of material taken in operation is largely in excess of the pharmacopœial quantities, shall not exceed the limit of 10 to 30 drops in a minute. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

“When the dregs of a tincture or similar preparation are to be subjected to percolation

after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid until the prescribed quantity has been obtained."—U. S.

Although, with proper management, good results may be obtained in the preparation of extracts and fluid extracts by using a funnel-shaped (usually termed a *conical*) percolator for exhausting the powder, experience has demonstrated that the so-called *cylindrical* percolator is to be preferred, having the shape described above, which represents the section of a long cone, and this is terminated below either by a funnel or by a shorter cone. The relative proportion of *diameter to height* of powder is of importance, since it is evident that with an increase of the latter the same fraction of menstruum must come into contact with a larger number of particles of the powder. Its height should be four or five times greater than its mean diameter. The *cover* of the percolator should not fit air-tight, or, if from the volatility of the menstruum, this should be desirable, a communication should be established by means of a glass tube between the receiving vessel and the top of the percolator for the equalization of pressure. Gum-cloth furnishes a convenient material for an ordinary cover.

In conducting a series of experiments on percolation Dr. Squibb (1866) proved, first, that there is a sufficient degree of uniformity of results to admit of the adoption of a model plan of proceeding applicable to drugs in general; second, that the extract or soluble matter yielded to the menstruum is not uniform in its chemical and therapeutical value as obtained during the different stages of the percolation, but diminishes in effective value far more rapidly than the extract does in weight; and third, that this decrease in value depends upon the difference in solubility between the active and inactive portions of the extract, and that the ratio of this decrease is about the same for drugs in general, provided the proper menstruum be used. Critical experiments made with seven different drugs proved that the first 12 fluidounces of the percolate contained from 61 to 78 per cent. of the total extract obtainable from 16 troy ounces of a drug with 3 or 4 pints of percolate, as directed by the Pharmacopœia of 1860, and that the first 16 fluidounces contained from 71 to 84 per cent. of the total amount of extract. Subsequently (1869), Samuel Campbell showed that some drugs may be practically exhausted by careful management on obtaining 1 fluidounce for every troyounce of the drug used. This principle, however, is applicable to those drugs only which are rather heavy, and at the same time are readily permeated by a menstruum in which the active principles are easily and freely soluble, so that complete exhaustion is attained without difficulty. The U. S. P. 1870 directed in most cases 24 fluidounces of percolate for 16 troyounces of drug, and regarded the latter then as practically exhausted. The present Pharmacopœia directs displacement to be continued until the drug is exhausted—a point which may be reached by careful manipulation without requiring finally long-continued evaporation. But while for fluid extracts the *exhaustion* of the material is mostly left to the good judgment of the pharmacist, definite quantities of percolate are usually directed for the extracts—sufficient to exhaust the material completely. In the light of the experience cited above it would seem that this might likewise have been left to the judgment of the experienced operator.

When the active principles possess a decided taste their gradual diminution in the percolate is easily ascertained; in other cases recourse may be had to chemical tests, especially in the presence of alkaloids. The color of the percolate alone is no reliable criterion for its medicinal strength, some drugs continuing to yield colored percolates after the active principles have been exhausted, while others still yield appreciable quantities of the latter after most of the coloring matter has been taken up. The strength of extracts and fluid extracts depends solely on the amount of the active principles, and not on the total amount of extractive matter, obtained.

For *moistening* the powder a definite quantity of menstruum is now directed which experience has shown to be most suitable: generally, this quantity is greater than was formerly thought desirable. The manner of *packing* described is the most convenient, the pressing of the whole amount of the powder in one operation giving better and more uniform results in the hands of most operators than if done in fractions. Ligneous

FIG. 115.

Tin Percolator, arranged for volatile liquids.

material requires to be very firmly packed, and when of more loose cellular structure the packing should be less firm, but in all cases it should be uniform. Again, when an alcoholic menstruum is used the packing must be correspondingly firmer as the menstruum is stronger in alcohol. When well packed, a disk of paper or muslin is spread upon the surface and the requisite menstruum poured upon it. Thus arranged, the material is permitted to macerate for 2 days, both orifices of the percolator being securely closed to prevent evaporation. The time directed for maceration is ample, but may be prolonged to 3 or 4 days without disadvantage, or for easily-exhausted drugs even shortened. It is to be observed that the powder is to remain constantly covered by a stratum of the menstruum; this precaution is of imperative necessity until the powder has been deprived of the greater proportion of its active principles, and the liquid in the percolator may be more than sufficient to displace the solution of the remainder.

After the exhaustion of the powder has been accomplished the absorbed alcohol may be recovered by distillation with steam, or, when this is impracticable, it may be obtained by percolation with a weaker alcohol, the alcoholic strength being gradually reduced until finally water is used for pushing the last portions of the percolate through. The more mucilaginous the material is, the greater the caution which should be exercised in this decrease of the alcoholic strength. The alcohol thus obtained requires to be rectified, and may usually be deprived of its foreign odor by distillation with a small quantity of potassium permanganate.

RE-PERCOLATION—or, as it has been called by Prof. Diehl, *fractional percolation*—is a process recommended by Dr. Squibb in 1866, and was more recently somewhat modified

FIG. 116.

Réal's
Filter-press.

with the view of obtaining more uniform results, the object being preparation of fluid extracts without the use of heat. The process may be briefly described as follows: 32 parts of powder are divided into four equal portions, one of which is moistened, packed, macerated, and then slowly displaced until exhausted. The percolate is collected in fractions, the first 6 parts being reserved, and the next fraction used for moistening the second portion of 8 parts of the powder, which is afterward macerated and displaced with the remaining fractions, the weakest being used last. Of this portion 8 parts of percolate are reserved. The third and fourth portions of 8 parts each of the powder are percolated in the same manner as the second portion, and, finally, the 4 reserved percolates are mixed to obtain 30 parts of fluid extract. The weaker percolates from the fourth portion are preserved for a subsequent operation, when from each portion of 8 parts of powder 8 parts of percolate are reserved. (See paper on "Fluid Extracts by Re-percolation" by Dr. Squibb, and "Report on Fluid Extracts" by Prof. Diehl, in *Proc. Am. Phar. Assoc.*, 1878.)

A series of percolators may be conveniently arranged on a retort-stand, and the rapidity of percolation regulated, as suggested by Dr. Squibb, by connecting the lower aperture of the percolator with a thin rubber tube, the end of which is raised high enough to prevent the liquid from escaping during maceration, and afterward lowered, so that the percolation may proceed in drops, the position of the rubber tube being changed to ensure uniformity and regularity; the last portions of the

FIG. 117.

Glass Percolators, with supply- and receiving-bottles.

liquid are withdrawn from the percolator, either by removing the rubber tube or by straightening it by sufficiently elevating the percolator. A uniform supply of menstruum may be provided for in various ways, the most simple of which is to invert a bottle containing the requisite quantity of liquid over the orifice of the percolator. The mouth of the bottle should be immediately above the disk covering the powder, and, if necessary, may be lengthened by a piece of rubber tubing.

Sectional percolation is a modification of this process proposed by William M. Thomson (1883). The percolator is an elongated cone, which may be taken apart in sections, each section forming a percolator, ending below with a perforated diaphragm of the same diameter as that of the top portion of the next section; the powder to be exhausted is packed in the different sections, and the liquid, percolating through from above, as it leaves one section is again uniformly distributed over the powder contained in the next.

A process for the preparation of fluid extracts without the use of heat deserves a passing notice, since from the employment of a very powerful press it is perhaps better adapted for the manufacturer than for the pharmacist. It was devised by N. S. Thomas (1865), and consists in moistening the ground drug with a portion of the menstruum, and after sufficient maceration expressing the liquid. The operation of maceration and expressing is repeated several times until the proper quantity of fluid extract is obtained. A very efficient press, serviceable for this purpose and for other pharmaceutical preparations, has been constructed by Mr. Charles T. George (*Proc. Penna. Phar. Assoc.*, 1878).

PERCOLATION UNDER PRESSURE.—The first notice of percolation under pressure was given by Count Réal (*Jour. de pharm.*, 1816, April), who constructed an apparatus known as *Réal's solution-press or filter-press*, and which consisted in a tin percolator surmounted by a tube which could be made 50 feet (15 M.) or more in length; after the fine, previously-moistened powder had absorbed all the menstruum provided for its exhaustion, the tube was filled with water, and the menstruum absorbed by the powder was thus forced out by hydrostatic pressure. The inconvenience of the long water-tube suggested its replacement by a column of mercury, which, communicating with a reservoir, forced the water through the powder. Semmelbauer (*Buchner's Repertorium*, 1817, iii.) already conceived the idea of using compressed air for the same purpose, and a suitable apparatus for this purpose was constructed by Dr. Romershausen, and is described in *Buchn. Repert.*, 1819, vi. p. 316. The process was subsequently applied by Boullay (*Jour. de pharm.*, 1833, June) to displacement under the pressure of a low column of liquid, as in the percolators at present in use. The necessity of saturating the powder with the menstruum without rendering it adhesive, and of firmly compressing the moistened powder, was early recognized as essential conditions for success. The same principle of percolating under pressure applies to the apparatuses more recently constructed by Duffield, Stearns, and others, in which the air in the receiver may be rarefied and that contained in the percolator above the powder may be compressed. Rosenwasser's percolator (1881) is simply Réal's press, with this addition, that the powder, by a screw arrangement, may be confined in any desired space, without the possibility of expansion on coming in contact with the bulk of the liquid percolating through it.

Evaporation.—Spontaneous evaporation at ordinary temperatures of the atmosphere is easily accomplished with ethereal and similar volatile liquids, but alcoholic tinctures, in order to avoid a too-prolonged contact with air, require a somewhat elevated temperature, that directed by the Pharmacopœia being usually about 50° C. (122° F.). Where a higher temperature exerts no injurious influence upon the important constituents, a *water-bath* is most convenient for the purpose; and since the evaporating liquid will always remain several degrees below the boiling-point of water, even though the water in the bath may be actively boiling, empyreuma is effectually prevented. *Steam-baths* will likewise be useful, provided the arrangements are such that the pressure of steam cannot, or only slightly, exceed that of the atmosphere. *Sand-baths* and other contrivances by which the temperature is likely to rise above 100° C. (212° F.) should be used only with due precautions. Evaporation is most successful if conducted from a shallow dish, with a current of dry air passing over the surface of the liquid, which may at the same time be agitated; but the use of metallic spatulas for stirring during evaporation is generally inadmissible: the

FIG. 118.

Water-baths.

FIG. 119.

proper material is porcelain or wood. Various mechanical contrivances have been constructed with the view of saving the manual labor and constant attendance in stirring, and they serve a good purpose.

In evaporating a tincture the alcohol is lost, but in many cases it is desirable to recover it, when *distillation* is resorted to. For pharmaceutical purposes a glass retort heated by a water-bath may be used. The apparatus, often called a "pharmaceutical still," serves a useful purpose; it is a rather shallow tin basin, which may be placed in a water-bath, and the head of which is provided on the inside with a gutter; the tincture to be concentrated is put into a porcelain evaporating-dish; this is placed in the still, and the moderate heat of a water-bath applied, when the alcohol will slowly evaporate, condense upon the inside of the cooled head, collect in the gutter below, and be discharged through the neck. Besides recovering the alcohol, this arrangement has also the advantage of keeping the liquid free from dust and other accidental impurities. For use on a small scale, Prof. Parrish has somewhat modified the steam evaporating-pan and still, and constructed an apparatus which is shown in Fig. 120. *A* is a boiler made of thick copper, which may

FIG. 120.

Steam-boiler, with Still.

be heated either by a furnace or by several Bunsen burners. Water is supplied through the valve *H*; *G* is a safety-valve; *E* is the valve for regulating the supply of steam, which is carried off through the exhaust-valve *F*.

FIG. 121.

Remington's Pharmaceutical Still.

The evaporating-pan, made of well-tinned copper, is coupled together with the steam-jacket *B*, upon the flanges of which is fitted the head *C*, and secured by means of clamps, the joint being made steam-tight by placing a coil of lampwick or loose cord between the flanges. If used for distillation, *C* is connected with a condenser; if for evaporation only, *C* is removed. By proper regulation at *E* and *F* either a very moderate heat may be applied to the pan or the temperature may be raised above the boiling-point of water.

A very serviceable pharmaceutical still has been constructed by Prof. Remington (1879). It is made of copper; the head, which is fastened in the same manner as the preceding, connects with a condenser formed of a combination of several Liebig's tubes, whereby the condensing surface is very materially increased. The still may be used in a water-bath or over direct fire, and if desired may be converted into a steam-bath by fastening a suitable dish as

an evaporating-pan upon the body of the still containing some water.

In many processes carried on in the arts *vacuum-stills* are used for the evaporation

of liquids, the boiling-point of which is lowered in proportion as the pressure within the apparatus is reduced to below that of the surrounding atmosphere. For operations on a small scale, and quite suitable for the requirements of the pharmacist, the *water-air-pump* described by Dr. Sprengel in 1865, and known also as Bunsen's water-air-pump, may be used with advantage. It is simply water descending in a perpendicular tube which laterally communicates with the interior of the otherwise hermetically-closed vessel containing the liquid to be evaporated; the descending column of water creates suction, the air in the apparatus being carried down with the water, and thus causes a partial vacuum, in which the liquid evaporates at a low temperature. The apparatus is well adapted for rapid filtration, washing of precipitates, evaporation, etc., but provision may also be made for condensing the vapors and recovering the menstruum.

Changes by Evaporation.—All plants contain one or more principles, which, though originally colorless, are very easily altered under the influence of air and heat, acquiring a yellow or brown color. It is not known whether the so-called *colorless extractive* is alike in all plants, nor is its composition known or the nature of changes produced under the conditions mentioned, except that the heat of boiling water and the prolonged action of oxygen will convert it ultimately into a blackish insoluble substance, to which the name *apotheme* has been given, and which appears to be allied to *humic*. Extractive is almost insoluble in absolute alcohol and ether, but dissolves freely in weaker alcohol and water, and is removed from its solutions by animal charcoal and hydrate of aluminium, the more readily after it has become colored by oxidation. It is with difficulty freed from all admixtures, and the terms sweet, bitter, acrid, etc. extractives refer to the same body in a more or less altered condition, combined or intimately mixed with other principles to which the peculiar taste is due. The injurious influence of air and heat upon the vegetable juices is mainly confined to the alterations of this extractive, and extends in a limited degree only to the majority of the well-defined principles. Its effects have often been much overrated, except as regards the appearance of the extracts. The color of the different extracts and fluid extracts varies with the nature of the drug from which they have been made, but should never be black. Fluid extracts should preserve the taste and also the odor of the drug, except in so far as both may be modified by the menstruum. The characteristic taste, and to some extent also the odor, of the drug should be perceived in the extracts, and these should yield a nearly clear or moderately turbid solution of the menstruum used in their preparation. Not to come up to these requirements is indicative of carelessness, and the presence of empyreumatic products proves the operation to have been slovenly.

Consistence of Extracts.—The Pharmacopœia recognizes three degrees of consistence—namely, 1. like thick honey (*Extr. mali*); 2. pilular consistence; and 3. dry. These degrees are practically the same as those adopted by the German Pharmacopœia, but designated as—1. thin extracts, of the thickness of fresh honey (mostly oleoresins); 2. thick extracts, which when cold cannot be poured from a vessel; and 3. dry extracts, which may be rubbed to powder. A pilular consistence is practically unattainable for most extracts unless some dry substance is added, like the chlorophyll to the inspissated juices of the British Pharmacopœia. The nearest degree of consistence attainable with some extracts is such that they may be formed into pills, which, however, do not retain their globular shape. Others, like *Extr. gentianæ*, *taraxaci*, etc., are even too soft for that purpose, while some, like *Extr. rhei*, etc., gradually become quite tough or hard. The addition of 5 per cent. of glycerin to some extracts is intended to preserve the proper consistence. Extracts which do not contain any fixed oil or hygroscopic constituents may usually be reduced to powder when sufficiently evaporated and cooled. On being warmed all extracts become softer, and, if pulverulent at the ordinary temperature, acquire sufficient pliability to be rolled into pills.

The *abstracts* admitted in the present Pharmacopœia are powdered extracts, which, however, have no simple relation to the extracts proper. The *powdered or dry narcotic extracts*, P. G., are identical with those of the Prussian Pharmacopœia of 1862, and are prepared by mixing 4 parts of the extract with 3 parts of finely-powdered liquorice-root, drying the mixture between 40° and 50° C. (104° and 122° F.), rubbing the residue to powder while warm, and adding sufficient powdered liquorice-root to make 8 parts. These are made for convenience in dispensing only, but, while they are well adapted for being added to powders, they cannot be used in mixtures, owing to their partial insolubility. The use of dextrin in place of liquorice-root, prescribed by the P. G. 1872, has been abandoned, most of the powders thus prepared being too hygroscopic.

Preservation.—The consistence of *extracts* nearly neutralizes any injurious effect

which contact with the atmosphere might otherwise exert, and the most ordinary care will therefore suffice to keep them unaltered for a considerable time. The sprinkling upon the softer extracts of a small quantity of alcohol has been recommended, but this is entirely unnecessary for those which are to some degree hygroscopic, and of little permanent utility for those which have a tendency to become tough. The difficulty may

generally be avoided by spreading a few drops of glycerin over the surface, or, as has been proposed, by working into the warm extract half its weight of glycerin and dispensing 50 per cent. more than prescribed. This plan has been adopted in principle by the U. S. P., but the glycerin has been reduced to 5 per cent.

The ordinary extracts are kept in jars of queensware, or, preferably, of porcelain or glass, with a cover of the same material. Small quantities may be kept in wide-mouthed vials with a very narrow shoulder, or in an ordinary tie-over jar enclosed in a tin-box just large enough to receive it and provided with a well-fitting cover to prevent absorption of moisture from the atmosphere or evaporation of the water contained in the extract. Extracts are rarely liable to mould unless they contain a considerable proportion of mucilaginous principles, and such are nearly always adapted to be brought to a dry condition. Dry extracts are in most cases preferably reduced to a granular or rather coarse powder. Extracts which have become too soft should be evaporated to the proper consistence by means of a water-bath, and those having become hard and unmanageable should be softened by the heat of a water-bath, when the requisite quantity of distilled water may be incorporated to bring them to the proper consistence.

For the preservation of *fluid extracts* the same precautions are required as for the preservation of most other liquid medicines. The bottles in which they are kept should be provided with a well-ground glass stopper or with a sound cork to prevent the slow evaporation of alcohol, which would occasion a change in the solvent power of the menstruum; and they should be placed in a position where they are exposed neither to the direct sunlight nor to any great or sudden changes in temperature. It should be remembered that perhaps all fluid extracts are saturated solutions of some of the principles naturally contained in the drug, and that their re-solution in the fluid extract from which they may have deposited in the cold can be effected only very gradually at the same temperature at which they previously existed in perfect solution.

Variation.—By Mohr's process (see above) for inspissated narcotic juices a number of inert principles are excluded from the extracts; the use of one menstruum in the preparation of extracts from dry drugs excludes many inert constituents. While it is known that drugs may vary in their medicinal activity within rather considerable limits, few or no analytical researches have been made as to the variation of the extracts prepared from such varying material by a uniform process. In the near future the progress of science will most likely require a standardizing of these preparations, as it has been already deemed necessary for the more important crude drugs.

Fluid extracts, if properly made, will fairly represent the drugs, and necessarily must vary to some extent in their efficacy; but the variation should be only within the limits of the variation which is unavoidable in the crude material.

EXTRACTUM ACONITI, U. S., P. G.—EXTRACT OF ACONITE.

Extractum aconiti radicit.—*Extract of aconite-root.* E.; *Extrait de racine d'aconit.* Fr.; *Akonitknollen-Extrakt.* G.

Preparation.—Aconite, in No. 60 powder, 100 parts (20 oz. av.); Tartaric Acid 1 part (146 grains); Glycerin, Alcohol, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or $9\frac{3}{4}$ fluidounces) of alcohol in which the tartaric acid has previously been dissolved, and pack it firmly in a cylindrical glass percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 300 parts (60 oz. av. or about $3\frac{1}{2}$ pints) of tincture are obtained or the aconite is exhausted. Reserve the first 90 parts (18 oz. av. or about 18 fluidounces) of the percolate, evaporate the remainder in a porcelain capsule at a temperature not exceeding 50° C. (122° F.) to 10 parts (2 oz. av.), add the reserved portion, and evaporate at or below the above-mentioned temperature until an extract of a pilular consistence remains.

Lastly, weigh the extract and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

Exhaust by maceration aconite-root with a mixture of alcohol sp. gr. .832 4 parts with water 3 parts, and evaporate to a thick extract.—*P. G.*

Alcohol appears to be the most appropriate menstruum, but the necessity for the use of tartaric acid is not apparent in the light of what is known about the alkaloids of aconite-root. The yield is about 16 per cent.; the color yellowish-brown. It should be remembered that this extract is from six to nine times stronger than that of aconite-leaves recognized by the *U. S. P.* 1870 under the same name; it is therefore advisable to designate in prescriptions the new pharmacopœial extract as *Extract. aconiti radiceis*.

Extractum aconiti, Br., is the inspissated juice of the fresh herb, and is appropriately prescribed as *Extract. aconiti herbae*. The process, which will serve as an example of the one adopted by that authority for inspissated narcotic juices, is as follows:

Take of the fresh leaves and flowering tops of aconite 112 pounds. Bruise in a stone mortar and press out the juice; heat it gradually to 130° F., and separate the green coloring matter by a calico filter. Heat the strained liquor to 200° F. to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green coloring matter previously separated, and, stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140° F. until the extract is of a suitable consistence for forming pills.—*Br.* The color is brown-green, and the extract contains the chlorophyll and mucilaginous constituents.

Medical Uses.—This extract of aconite-root is represented to be about nine times as strong as the preparation of the leaves, which was official in the Pharmacopœia of 1870. Its *dose* may be stated as $\frac{1}{4}$ to $\frac{1}{2}$ grain (Gm. 0.01–0.02). The dose of the British extract is 1 to 2 grains (Gm. 0.06–0.12).

EXTRACTUM ACONITI FLUIDUM, *U. S.*—FLUID EXTRACT OF ACONITE.

Extractum aconiti radiceis fluidum.—Fluid extract of aconite-root, *E.*; *Extrait liquide de racine d'aconit*, *Fr.*; *Flüssiges Aconitknollen-Extrakt*, *G.*

Preparation.—Aconite, in No. 60 powder, 100 Gm. (25 oz. av.); Tartaric Acid 1 Gm. ($\frac{1}{4}$ oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 11 $\frac{1}{2}$ fluidounces) of alcohol in which the tartaric acid has previously been dissolved, and pack it firmly in a cylindrical glass percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the aconite is exhausted. Reserve the first 90 Ccm. (21 $\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

In this preparation, as in the extract, the addition of tartaric acid is of no apparent utility. The fluid extract is practically of the same strength as the Linimentum aconiti, *U. S. P.* 1870 and *Br. P.*

Medical Uses.—Each minim of this preparation represents about 1 grain of aconite-root. Its commencing *dose* should not exceed 1 minim (Gm. 0.06), and it is more prudent to use only half that quantity. This extract is a convenient addition to liniments intended to relieve neuralgic and rheumatic pains.

EXTRACTUM ALOES AQUOSUM, *U. S.*—AQUEOUS EXTRACT OF ALOES.

Extractum aloes socotrinæ, Br.; *Extract of Socotrine aloes, E.*; *Extrait d'aloès socotrin*, *Fr.*; *Socotora Aloe-Extrakt*, *G.*

Preparation.—Aloes 100 parts (8 oz. av.); Boiling Distilled Water 1000 parts (80 oz. av. or 5 pints). Mix the aloes with the water in a suitable vessel, stirring constantly, until the particles of aloes are thoroughly disintegrated, and let the mixture stand for 12 hours; then pour off the clear liquor, strain the residue, mix the liquids, and evaporate to dryness by means of a water- or steam-bath.—*U. S.*

The *Br. P.* process is identical with the foregoing, as is also that for *Extractum aloes barbadensis*, *Br.*, prepared from Barbadoes aloes. The *Extractum aloes, P. G.*, is made

in the same manner from Cape aloes, using 5 parts of boiling water and decanting after two days. *Extractum aloes acido-sulphurico correctum* was obtained by diffusing 8 parts of the extract in 32 parts of distilled water, adding gradually 1 part of sulphuric acid and evaporating to dryness.

Socotrine aloes yields from 18 to 25 per cent. of aqueous extract. Cape aloes about twice that amount. The extracts are yellowish-brown powders and yield turbid solutions with water. According to Tilden (1870), an efficient extract of aloes is obtained by evaporating the mother-liquor from which aloin has been deposited, but this should never be substituted for the official product.

Off. Prep.—Decoct. aloes comp., Extract colocynth. comp., *Br.*

Medical Uses.—It may be given for the same purposes as the extract of Barbadoes or Socotrine aloes or as aloes itself, and in the same *dose*—from 1 to 6 grains (Gm. 0.06–0.40).

EXTRACTUM ANTHEMIDIS, *Br.*—EXTRACT OF CHAMOMILE.

Extractum chamomillæ Romanæ.—*Extrait de camomille romaine*, Fr.; *Römisch-Kamillen-Extrakt*, G.

Preparation.—Take of Chamomile-Flowers 1 pound; Oil of Chamomile 15 minims; Distilled Water 1 gallon. Boil the chamomile with the water until the volume is reduced to one-half, then strain, press, and filter. Evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills, adding the oil of chamomile at the end of the process.—*Br.*

It is a dark-brown extract having the odor and bitter taste of chamomile. It would seem not to be very difficult to work out a better process, in which the long boiling should be avoided.

EXTRACTUM ANTHEMIDIS FLUIDUM.—Fluid extract of chamomile, *E.*—This is sometimes called for. Prof. Procter (1857) suggested exhaustion with alcohol and diluted alcohol, and after evaporation preservation by sugar. Mr. Samuel Campbell (1870) suggested a menstruum composed of 2 measures of alcohol and 1 measure each of glycerin and water.

Medical Uses.—Like extract of gentian, it is a convenient excipient for tonic medicines given in the pilular form, especially quinia and the salts of iron. It is by itself a mild stomachic tonic. *Dose*, from 2 to 10 grains (Gm. 0.10–0.60).

EXTRACTUM ARNICÆ RADICIS, *U. S.*—EXTRACT OF ARNICA-ROOT.

Extrait de racine d'arnica, Fr.; *Arnika-Extrakt*, *Wohlfurth-Extrakt*, G.

Preparation.—Arnica-Root, in No. 60 powder, 100 parts (20 oz. av.); Glycerin, Diluted Alcohol, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 8½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until 300 parts (60 oz. av. or about 3½ pints) of tincture are obtained or the arnica-root is exhausted. Reserve the first 90 parts (18 oz. av. or about 17½ fluidounces) of the percolate; evaporate the remainder to 10 parts (2 oz. av.) at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The yield is about 30 per cent. The extract is brown, of a slight odor, and has the bitter and acrid taste of the root. Formerly extract of arnica was prepared from the flowers. A mixture of 2 parts of alcohol and 1 of water yields a better extract, although arnica-root is completely exhausted by diluted alcohol.

Off. Prep.—Emplastrum arnicæ, *U. S.*

Medical Uses.—*Dose*, from 3 to 5 grains (Gm. 0.20–0.30).

EXTRACTUM ARNICÆ RADICIS FLUIDUM, *U. S.*—FLUID EXTRACT OF ARNICA-ROOT.

Preparation.—Arnica-Root, in No. 60 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Gm. (24 fluidounces). Moisten the powder

with 40 Gm. (8 oz. av. or 8½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the arnica-root is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The fluid extract is of a reddish-brown color, and has the bitter and acrid taste of arnica-root.

Medical Uses.—*Dose*, 10 to 30 minims (Gm. 0.60–2).

EXTRACTUM AROMATICUM FLUIDUM, *U. S.*—AROMATIC FLUID EXTRACT.

Extrait liquide des aromates, Fr.; *Flüssiges Gewürzextrakt*, G.

Preparation.—Aromatic Powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8¼ oz. av. or 10½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the aromatic powder is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This newly-introduced preparation is of a rich red-brown color, and has the warm aromatic taste of the powder.

Medical Uses.—This tincture of several aromatics is convenient as a flavoring ingredient of mixtures, and may be used alone to relieve flatulent colic in the *dose* of half a teaspoonful or more (Gm. 2).

EXTRACTUM AURANTII AMARI FLUIDUM.—FLUID EXTRACT OF BITTER ORANGE-PEEL.

Extrait liquide d'écorce d'orange amère, Fr.; *Flüssiges Pomeranzenschalen-Extrakt*, G.

Preparation.—Bitter Orange-Peel, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts of alcohol with 1 part of water (or, by measure, 25 fluidounces of alcohol and 10½ fluidounces of water), and, having moistened the powder with 35 Gm. (8¼ oz. av. or 9½ fluidounces) of the mixture, pack it moderately in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the orange-peel is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

In preparing this new official fluid extract it should be remembered that the orange-peel should consist almost exclusively of the glandular epidermal layer, known in commerce as Curaçoa orange-peel. Prepared of good material, the preparation will be of a yellowish-brown color and have the agreeable odor and pleasantly bitter taste of the peel.

Medical Uses.—A flavoring agent especially suitable for bitter mixtures, and also as a mild stimulant tonic in the *dose* of a fluidrachm (Gm. 4).

EXTRACTUM BELÆ LIQUIDUM, *Br.*—LIQUID EXTRACT OF BAEL.

Extrait liquide de bael, Fr.; *Flüssiges Baelaextrakt*, G.

Preparation.—Take of Bael-Fruit 1 pound; Distilled Water 12 pints; Rectified Spirit 2 fluidounces. Macerate the bael for 12 hours in one-third of the water; pour off the clear liquor; repeat the maceration a second and third time for 1 hour in the remain-

ing two-thirds of the water; press the marc and filter the mixed liquors through flannel. Evaporate to 14 fluidounces, and when cold add the rectified spirit.—*Br.*

This fluid extract represents 1 airoirdupois ounce of bael in each fluidounce. Imperial measure. The amount of spirit seems very small for such a concentrated liquid.

Medical Uses.—In the *dose* of 1 or 2 fluidrachms (Gm. 4–8) it may be given in chronic diarrhœa and dysentery.

EXTRACTUM BELLADONNÆ ALCOHOLICUM, *U. S.*—ALCOHOLIC EXTRACT OF BELLADONNA.

Extrait de belladone alcoolique, Fr.; Spirituöses Tollkirschen-Extrakt, G.

Preparation.—Belladonna-Leaves, in No. 60 powder, 100 parts (20 oz. av.); Alcohol 200 parts (40 oz. av. or 47 fluidounces); Water 100 parts (20 oz. av. or 19 fluidounces); Glycerin, Diluted Alcohol, each a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 40 parts (8 oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding first the remainder of the menstruum, and then diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the belladonna-leaves are exhausted. Reserve the first 90 parts (18 oz. av. or about 18 fluidounces) of the percolate, evaporate the remainder to 10 parts (2 oz. av.) at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The corresponding preparation of the *U. S. P.* 1870, and that of the French Codex, are made with alcohol of 61 and 60 per cent. by volume; the present Pharmacopœia directs the menstruum to be 60.5 per cent. by weight—an increase of strength for which there is no necessity; nor is the addition of glycerin necessary, the extract retaining its consistence if properly prepared and kept with ordinary care. The yield is about 22 per cent. The color is greenish-brown or brown-green, and the extract has the bitter taste of belladonna.

Off. Prep.—Unguentum belladonnæ, *U. S.*

EXTRACTUM BELLADONNÆ *Br., P. G.*, is the inspissated juice of fresh belladonna-herb, prepared in accordance with the formulas outlined on page 602. The extract of *Br. P.* is brown-green, of *P. G.* brown; the yield by the latter is 3 to 3½ per cent. On keeping, crystals are formed in the extract, which were found by Attfield (1862) to be potassium chloride and nitrate; according to Biltz, crystals of asparagin are sometimes observed.

Medical Uses.—The local applications of this, as of all other narcotic extracts, are numerous. Softened with water or mixed with oil, it enters into many magistral formulas for the relief of local pains, especially those of a *neuralgic* sort. A more elegant form for this purpose is belladonna plaster. The relaxing and anodyne operation of the extract is used to allay spasm of the muscles surrounding canals, as the *ureter, bladder, urethra, os uteri, vagina*, and *rectum*, when irritation excites their contraction. In these several cases the softened extract may be rubbed in as near as possible to the seat of pain, or it may be introduced in a suppository into the vagina or rectum. When applied to the prepuce in *phimosis* and in *paraphimosis* it sometimes reduces the engorgement and stricture. Rubbed on the forehead or eyelids, it was formerly much used to *dilate the pupil*, but the more cleanly solution of atropia is to be preferred. It may be given internally for all the purposes to which belladonna is appropriate. Extract of belladonna is of uncertain strength, and its *dose* is therefore variable. A quarter of a grain (Gm. 0.01) may be given three times a day, and the quantity gradually increased until the state of the pupil denotes the degree of its action.

The *dose* of the British preparation is stated to be ¼ to ½ gr. (Gm. 0.016–0.03), and of the German extract gr. i (Gm. 0.06).

EXTRACTUM BELLADONNÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF BELLADONNA.

Extractum belladonnæ radicis fluidum, U. S. 1870.—Fluid extract of belladonna-root, E.; Extrait liquide de racine de belladone, Fr.; Flüssiges Tollkirschenwurzel-Extrakt, G.

Preparation.—Belladonna-Root, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8½ oz. av. or 10½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the belladonna-root is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Since a fluid extract of belladonna-leaves is occasionally employed, the above preparation should always be designated by the title of the *U. S. P.* 1870, given above. Care should be taken in the selection of belladonna-root, which should not be woody. This fluid extract has a reddish-brown color, and may be used for the preparation of belladonna plaster.

Off. Prep.—Linimentum belladonnæ, *U. S.*

Medical Uses.—The *dose* of this preparation is from 1 to 2 minims (Gm. 0.06–0.12). It is one of the most efficient representatives of belladonna.

EXTRACTUM BRAYERÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF BRAYERA.

Extractum koso fluidum.—*Fluid extract of koso*, *E.*; *Extrait liquide des kouso*, *Fr.*; *Flüssiges Kosoextrakt*, *G.*

Preparation.—Brayera, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 11½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the brayera is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Alcohol is a good solvent for the active principles of koso. The fluid extract has a brownish-green color, possesses the unpleasantly bitter and acrid taste of the drug, and if properly made produces only a slight deposit.

Medical Uses.—This preparation is intended to supplant the infusion and decoction of brayera, but its efficacy has not yet been demonstrated. The *dose* may be stated at 2 or 3 teaspoonfuls (Gm. 8–12); but doses twice as large have been given.

EXTRACTUM BUCHU FLUIDUM, *U. S.*—FLUID EXTRACT OF BUCHU.

Extrait liquide de bucco, *Fr.*; *Flüssiges Buccoextrakt*, *G.*

Preparation.—Buchu, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts of alcohol with 1 part of water (or, by measure, 25 fluidounces of alcohol and 10½ fluidounces of water), and, having moistened the powder with 30 Gm. (7½ oz. av. or 8 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the buchu is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The volatile oil and other medicinal principles are dissolved and kept in perfect solution by the menstruum directed, if proper care be taken to prevent the evaporation of alcohol. Alcohol of this strength was first suggested for the purpose by Prof. I. J. Grahame in 1859, and experience has shown that this fluid extract is much superior to that made with alcohol. The color is a deep olive-brown, and the odor and taste of buchu-leaves are well marked.

Medical Uses.—This fluid extract is inferior to the infusion of buchu for diseases of the urinary organs, but in default of that preparation may be prescribed in *doses* of 20 to 30 minims (Gm. 1.20–2.00), very largely diluted with water.

EXTRACTUM CALAMI FLUIDUM, U. S.—FLUID EXTRACT OF CALAMUS.

Extrait liquide d'acore vrai, Fr.; Flüssiges Kalmusextrakt, G.

Preparation.—Calamus, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8½ oz. av. or 10¼ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the calamus is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

Made from peeled calamus, this fluid extract is of a brownish-yellow color, but if prepared from the unpeeled rhizome, which is now to be used, it is of a considerably darker tint, the characteristic odor and taste being likewise more prominent. For preparing the powder the air-dry calamus should be dried over unslaked lime, but not by heat, which would expel much of the volatile oil. In view of the large intercellular passages contained in the tissue of calamus a powder passing through a No. 40 or No. 30 sieve would seem to be sufficiently fine for ready extraction.

(For *Extractum calami, P. G.*, see page 349.)

Medical Uses.—It may be used in all the cases for which calamus is appropriate. It is a convenient form of that drug. *Dose*, 10 to 20 minims (Gm. 0.60–1.30).

EXTRACTUM CALUMBÆ, Br.—EXTRACT OF CALUMBA.

Extractum columbo.—Extrait de colombo, Fr.; Kolombo-Extrakt, G.

Preparation.—Take of Calumba-Root, cut small, 1 pound; Distilled Water 4 pints. Macerate the calumba with 2 pints of the water for 12 hours, strain, and press. Macerate again with the same quantity of water; strain, and press as before. Mix and filter the liquors, and evaporate them by the heat of a water-bath until the extract is of a suitable consistence for forming pills.—Br.

The yellowish-brown extract contains the mucilaginous and bitter principles of columbo. The process of the French Codex, with alcohol of 60 per cent. by volume, yields a better extract, which is less liable to mould; the yield is 14 to 16 per cent.

Medical Uses.—This preparation, which in its action differs but little from the extracts of quassia and gentian, may be prescribed in the *dose* of from 2 to 10 grains (Gm. 0.10–0.60).

EXTRACTUM CALUMBÆ FLUIDUM, U. S.—FLUID EXTRACT OF CALUMBA.

Extrait liquide de colombo, Fr.; Flüssiges Kolomboextrakt, G.

Preparation.—Calumba, in No. 20 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 30 Gm. (7½ oz. av. or 7¾ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the calumba is exhausted. Reserve the first 70 Ccm. (16¾ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

The present Pharmacopœia directs a stronger alcoholic menstruum for the tincture than for the fluid extract: the employment of a menstruum composed of 2, or even 3,

parts of alcohol and 1 part of water would ensure a more permanent fluid extract. It is of a rich orange-brown color and possesses a strongly bitter taste.

Medical Uses.—It is a convenient substitute for the infusion, and may be prescribed in doses of a fluidrachm in 2 fluidounces (Gm. 4 in Gm. 64) of water.

EXTRACTUM CANNABIS INDICÆ, U. S., Br., P. G.—EXTRACT OF INDIAN CANNABIS.

Extrait de chanvre indien, Fr.; Indisch Hanfextrakt, G.

Preparation.—Indian Cannabis, in No. 20 powder, 100 parts (20 oz. av.); Alcohol a sufficient quantity. Moisten the powder with 30 parts (6 oz. av. or 7 fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding alcohol until 300 parts (60 oz. av. or about 4 pints) of tincture are obtained or the cannabis is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence.—U. S.

The processes of the Br. P. and P. G. are practically identical with the foregoing, except that the drug is exhausted by maceration. The yield is from 12 to 14 per cent. The extract is of a blackish-green color, and has a slight but heavy narcotic odor and a bitter taste. It should be completely insoluble in water, and dissolve in alcohol, ether, chloroform, and oil of turpentine; its alcoholic solution should be precipitated by aqueous solution of potassa or soda, the resin being insoluble in alkalis. Nitric acid converts the extract into an orange-red resin, which after washing with water has the color of gamboge (Procter, 1864).

Medical Action and Uses.—This extract varies so greatly in activity that its dose cannot be definitely fixed. Half a grain (Gm. 0.03) of a specimen not before tested should be given at first, and the dose gradually increased until its sensible effects are produced.

EXTRACTUM CANNABIS INDICÆ FLUIDUM, U. S.—FLUID EXTRACT OF INDIAN CANNABIS.

Extrait liquide de chanvre indien, Fr.; Flüssiges Indisch Hanfextrakt, G.

Preparation.—Indian Cannabis, in No. 20 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 30 Gm. (7½ oz. av. or 8½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the Indian cannabis is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

There is scarcely any necessity for this preparation, since the extract of Indian cannabis is readily soluble in alcohol. The fluid extract is of a dark-green color. If properly prepared it may be used for the extemporaneous preparation of the extract, and this extract should have the characteristics mentioned under the preceding article.

Medical Uses.—As each minim represents a grain of Indian cannabis, the fluid extract may be given in commencing doses of from ½ to 1 minim (Gm. 0.12–0.30).

EXTRACTUM CAPSICI FLUIDUM, U. S.—FLUID EXTRACT OF CAPSICUM.

Fluid extract of red pepper, E.; Extrait liquide de capsique, de piment des jardins, Fr.; Flüssiges Spanisch-Pfefferextrakt, G.

Preparation.—Capsicum, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 50 Gm. (12½ oz. av. or 14½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator;

then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the capsicum is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

There is likewise little need for this preparation, the drug being already represented by the oleoresin and the tincture. The fluid extract is of a rich brown-red color, yields a turbid mixture with water, and has the hot taste of the drug.

Medical Uses.—*Dose*, 1 to 2 minims (Gm. 0.6–0.12).

EXTRACTUM CARNIS.—EXTRACT OF MEAT.

Extractum carnis Liebig.—*Extract of beef*, E.; *Extrait de viande de Liebig*, Fr.; *Liebig's Fleischextrakt*, G.

Preparation.—Extracts of meat have been prepared for many years. Thouvenel exhausted fresh meat with alcohol, and Van Mons used the same menstruum for dry meat. Cadet de Gassicourt recommended the meat to be minced, mixed with cold water, the liquid expressed, boiled, skimmed, and evaporated. In 1854, Liebig published a formula for preparing a *broth for invalids* as follows: ½ pound of fresh meat is finely chopped and macerated for 1 hour with 1 pound of cold distilled water, to which 4 drops of hydrochloric acid and from 30 to 60 grains of table-salt are added. The mass is then displaced on a colander, a little water being added, until 1 pound of percolate has been obtained. The clear liquid has a red color and contains the albuminoids of the meat in solution. In 1859 the Bavarian Pharmacopœia adopted a process for extract of meat in which chopped meat was exhausted with hot water, and the expressed liquid, carefully freed from fat and albumen, was evaporated.

Since then factories have been established in different parts of South America, Australia, and the United States, where cattle are abundant and cheap. In the majority of these establishments Liebig's process appears to be followed, perhaps with some slight modification. At Fray-Bentos, on the river Uruguay, where a factory was conducted under the direction of Liebig, the extract, according to F. Müller (1868), is prepared as follows: The freshly-slaughtered meat is allowed to cool for 24 hours, and then ground into a pulpy mass by passing it between iron rollers furnished with small projections. The pulp is stirred with water for about an hour, strained through sieves, the fat carefully removed, and the liquid evaporated in steam-pans, a current of air being continuously passed over the surface. At a certain state of concentration the liquid is filtered, and the evaporation continued until the extract is transferred to well-glazed stoneware jars, which are carefully covered.

Properties.—Thus prepared, extract of meat is of a brown color, usually somewhat granular, and has a pleasant odor suggestive of roasted meat, and a characteristic, distinctly saline, and faintly acidulous taste. It is completely soluble in water, yielding a clear solution, which on the addition of a little table-salt has the flavor of beef-broth. When dried at the temperature of 110° C. (230° F.) 100 parts of the extract should lose not over 22 parts of moisture, and after incineration not less than 18 parts of ashes should be left, containing only a small quantity of sodium chloride. If 100 parts of the extract are digested with alcohol, and the liquid filtered and evaporated, not less than 56 parts of extract should be obtained (*P. G.* 1872). The figures given by Liebig himself as indicating the limits of variation in extract of meat prepared by his process are for *moisture* 16 to 22 per cent.; *ash* 18 to 22 per cent.; *extractive*, soluble in 80 per cent. alcohol, 56 to 66 per cent. Niederstadt (1881) gives the actual variation of the commercial Fray-Bentos extract as follows: *moisture* 13.2–29.2; *nitrogen* 2.6–9.04; *organic matter* 49.5–68.7; *ash* 10.5–21.4 per cent.; the ash contains potassa 30.1–32.5 and phosphoric acid 36.5–38.0 per cent. The absence of chloride of sodium in meat-juice is proven by precipitating first the salts of inosic acid by an equal bulk of alcohol, and then adding 5 volumes of alcohol, when the mixture will separate into two layers, the lower of which, about one-twentieth of the whole, on evaporation at a low temperature will yield prisms of the chloride of potassium containing not a trace of sodium salt.

The amount of nitrogen in extract of meat is sometimes as low as 2.6 per cent., but if made of good beef usually between 9 and 10 per cent., and depends chiefly on the presence of *creatin*, *creatinin*, *globulin*, and *urea*. The solution in water of the extract

usually yields a slight precipitate with tannin, which, according to Eichhorn (1867), is due to the presence of a nitrogenated body which somewhat resembles gelatin, but is not identical with it. Werner (1868), however, states that, if in preparing the extract the temperature of 60° C. (140° F.) be not exceeded, the aqueous solution will give no reaction for gelatin. It would seem, therefore, best to evaporate the liquid under reduced pressure. It is well known, however, that some extracts of meat which have appeared in our market have contained large quantities of gelatin. (See paper by A. E. Ebert in *Proc. Amer. Phar. Assoc.*, 1871, p. 512.)

Other extracts of meat, liquid as well as solid, have from time to time claimed attention, some of the former containing the soluble albuminous compounds or the ground flesh-fibres. In 1873, Prof Leube recommended an extract in which the meat-fibrin was emulsified by heating meat, free from fat and bones and chopped fine, in very diluted hydrochloric acid until almost completely disintegrated. At the present time peptones are used in preference to this preparation. (See PEPSINUM.)

Physiological Action and Medical Uses.—It appears to be too often overlooked that Liebig, to whom is due the vogue of beef-tea during the last quarter of a century, expressly declared it to be incapable of promoting nutrition, and that it is to be classed as nervous food, along with tea, coffee, and alcohol, and even as inferior to the last—a judgment which has been expressed in almost identical words by Virchow and emphasized by Sibson, Brunton, and many others. The small proportion of creatin it may contain does not materially alter this estimate. Its 2½ per cent. of albumen, according to some modes of preparation, is altogether eliminated in Liebig's extract, and the gelatin almost completely, leaving the organic alkaloids and acids and the salts. That these act as temporary nervous stimulants there can be no doubt; but the popular impression is that beef-tea is a substitute for food, and hence it often happens that the patient is plied with it inordinately, with the result of provoking vomiting or diarrhœa. That it often occasions the latter when habitually used as a substitute for food, to repair fatigue, or to fortify the body or mind for an unusual exertion, is probably within the experience of many physicians. Sibson, alluding to its use in diarrhœa, and especially in that of typhoid fever, declares that he looks "upon this fluid in the light of a poison in such cases," and strongly condemns its use in Bright's disease as burdening the already overtaxed kidneys with the duty of eliminating this non-assimilable matter. It is, however, rather indirectly than directly injurious by being used as a nutrient—a function which it has no claim to perform. (On the other hand, it has not that poisonous operation which science, "falsely so called," attributed to it through Kemmerich in 1868. He arrived at the singular conclusion that concentrated cold extract of horse-flesh injected into the stomach of dogs in small doses increases the number and strength of the heart's pulsations, but that in large doses it kills, with all the appearances of cardiac paralysis. This remarkable result he attributes to the potash salts of the meat! In 1880, Mr. Masterman (*Lancet*, Oct. 1880, p. 562) showed that beef-tea is analogous to urine, except that it contains less urea and uric acid, and that it is merely a stimulant; and Dr. Neale (*Practitioner*, xxvii. 343) calls attention to the fact that in several countries, including South America and Eastern Asia, the urine of young persons is used as a medicinal stimulant.

The stimulant and non-nutritious qualities of beef-tea render it peculiarly fitted for the treatment of the greater number of acute *febrile diseases*. Nature protests against the use of food in them by the repugnance of the patients to taking it and by the aggravation of the fever which it induces. During the augment and acme of these affections food in a literal sense heaps fuel on the fire, but in many of them the animal mechanism must be kept in such active movement as to enable it to resist the disintegrating tendencies of the disease, and afterward to throw off the effete accumulations. This beef-tea aids in accomplishing, and in the same manner as alcohol. When that end is attained, and when the fever has declined, the preparation holds only a secondary place in the treatment, the first being occupied by true nutrients, which are better prepared by culinary skill than by chemical science. No more serious mistake can be made in the treatment of acute diseases, when the febrile stage has passed by, than to continue to administer beef-tea, soups, and jellies. By such agents the patient may literally die of inanition while being gorged with what erroneously passes for food. Feeding by the rectum with beef-tea is, if possible, of even more temporary utility than when this preparation is given by the stomach. *Pancreatic emulsion* is more efficient. It is highly recommended in various affections of the stomach when the mucous coating requires to be protected from irritation, in convalescence from typhus, etc., and may be combined

with broth or with Liebig's extract of meat, or milk and powdered cracker (hard biscuit) may be used alternately with it. It has been employed with marked advantage in cases of fatty *diarrhoea* due to obstruction of the pancreatic secretion and in the *wasting diseases* of children induced by artificial feeding. It also promotes the digestion and assimilation of *cod-liver oil*.

EXTRACTUM CASTANÆ FLUIDUM, U. S.—FLUID EXTRACT OF CASTANEA.

Fluid extract of chestnut-leaves, E.; *Extrait liquide de feuilles de châtaignier*, Fr.; *Flüssiges Kastanienblätter-Extrakt*, G.

Preparation.—Castanea, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Pour 500 Ccm. (125 oz. av. or 7½ pints) of boiling water upon the powder, allow it to macerate for 2 hours, then express the liquid, transfer the residue to a percolator, and pour water upon it until the powder is exhausted. Evaporate the united liquids on a water-bath to 200 Ccm. (3 pints), let cool, and add 60 Ccm. (14½ fluidounces) of alcohol. When the insoluble matter has subsided separate the clear liquid, filter the remainder, evaporate the united liquids to 80 Ccm. (19¼ fluidounces), and add to it when cold enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

It is well known that hot water extracts the virtues of chestnut-leaves. The toughness of the fibro-vascular tissue (veins) of the latter render their reduction to a powder of the required fineness a matter of difficulty. This is practically recognized by the Pharmacopœia in ordering the partial extraction of the leaves by hot maceration and expression; a repetition of this manipulation with one-half the amount of hot water would have virtually exhausted the drug, provided a sufficiently powerful press be used. By clarification with $\frac{3}{10}$ volume of alcohol albuminous and some mucilaginous matters are removed. The finished fluid extract is preserved by alcohol equal to nearly one-fourth its measure; formerly, it was customary to use sugar for this purpose. The fluid extract is reddish-brown, and of a slight odor and of a strongly but pleasantly astringent taste. Mr. A. Robbins states that there is no special difficulty in exhausting chestnut-leaves by percolation if a weak alcoholic menstruum be used, the most suitable being composed of alcohol 1 part and water 2 parts, and the first 80 parts of this mixture being used with 20 parts of glycerin.

Medical Uses.—*Dose*, 1 to 2 fluidrachms (Gm. 4–8).

EXTRACTUM CHIMAPHILÆ FLUIDUM, U. S.—FLUID EXTRACT OF CHIMAPHILA.

Extrait liquide de pyrole ombellée, Fr.; *Flüssiges Doldenmangold-Extrakt*, G.

Preparation.—Chimaphila, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. (2½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (25 fluidounces). Mix the glycerin with 90 Gm. (22½ oz. av. or 23½ fluidounces) of diluted alcohol. Moisten the powder with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, and pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the chimaphila is exhausted. Reserve the first 70 Ccm. (16¾ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

The fluid extract has the sensible properties of the leaves in a high degree, but on keeping a considerable precipitate is formed, which is to some extent obviated by a slight increase of the alcoholic strength. In this and most other processes in which glycerin is used, this is directed to be mixed with diluted alcohol (or alcohol) sufficient to make more than 100 Ccm. (24 fluidounces); a considerable proportion of the glycerin enters the weak percolate, and renders its evaporation to a soft extract difficult.

Medical Uses.—This preparation is less eligible than the decoction. *Dose*, a fluidrachm (Gm. 4), largely diluted, three or four times a day.

EXTRACTUM CHIRATÆ FLUIDUM, U. S.—FLUID EXTRACT OF CHIRATA.*Extrait liquide de chirette, Fr.; Flüssiges Chirettaextrakt, G.*

Preparation.—Chirata, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. (2½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 90 Gm. (22½ oz. av. or 23¼ fluidounces) of diluted alcohol. Moisten the powder with 35 Gm. (8¼ oz. av. or 8¾ fluidounces) of the mixture, and pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the chirata is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

The fluid extract is reddish-brown, and has the intensely bitter taste of the drug. The bitter principles of chirata being soluble in water, a largely aqueous menstruum is indicated for this drug. Although precipitation takes place after some time, the active principles are probably not affected thereby.

Medical Uses.—*Dose*, about 20 minims (Gm. 1.30).

EXTRACTUM CIMICIFUGÆ FLUIDUM, U. S.—FLUID EXTRACT OF CIMICIFUGA.*Extrait liquide d'actée à grappes, Fr.; Flüssiges Cimicifuga-Extrakt, G.*

Preparation.—Cimicifuga, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 25 Gm. (6¼ oz. av. or 7¼ fluidounces) of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cimicifuga is exhausted. Reserve the first 90 Cem. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This has all the sensible properties of the drug from which it was made, and is a permanent preparation. Owing to difference in manipulation, the corresponding fluid extract *U. S. P. 1870* was slightly weaker in alcohol, but remained unaltered on keeping.

Medical Uses.—This preparation is greatly preferable to the decoction, which was formerly used. *Dose*, from 30 minims to a fluidrachm (Gm. 2–4).

EXTRACTUM CINCHONÆ, U. S.—EXTRACT OF CINCHONA.*Extractum chinæ spirituosum, P. G.—Extract of calisaya-bark, E.; Extrait de quinquina jaune, Fr.; Weingeistiges China-Extrakt, G.*

Preparation.—Yellow Cinchona, in No. 60 powder, 100 parts (20 oz. av.); Alcohol 300 parts (60 oz. av. or 70¼ fluidounces); Water 100 parts (20 oz. av. or 19¼ fluidounces); Glycerin, Diluted Alcohol, each a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 35 parts (7 oz. av. or 7¾ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until 400 parts (5 pounds av. or about 5 pints) of tincture are obtained or the cinchona is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The present process is a great improvement over that of 1870, when alcohol, followed by water, was the menstruum. The yield varies between about 12 and 16 per cent. The

extract is of a reddish-brown color, is only partly soluble in water, and has the persistently bitter taste of cinchona. Its tendency to become dry on keeping is sought to be prevented by glycerin. The German Pharmacopœia directs its spirituous extract of cinchona to be made with alcohol spec. grav. .894, and to be evaporated to dryness; it recognizes also an *Extractum chinæ aquosum*, s. *Extractum chinæ frigide paratum*, which is obtained by evaporating the cold aqueous infusion of cinchona-bark. The cinchona extracts of the French Codex are prepared with boiling water.

Medical Uses.—Extract of cinchona, since it possesses all the virtues of Peruvian bark, would for many purposes be preferable to quinine were it less bulky. The dose is from 10 to 30 grains (Gm. 0.60–2.00).

EXTRACTUM CINCHONÆ FLUIDUM, U. S.—FLUID EXTRACT OF CINCHONA.

Extractum cinchonæ flavæ liquidum, Br.; *Extractum chinæ calisayæ fluidum*.—*Liquid extract of yellow cinchona- or calisaya-bark*, E.; *Extrait liquide de quinquina jaune*, Fr.; *Flüssiges Chinaextract, Kalisayarinden-Extrakt*, G.

Preparations.—Yellow Cinchona, in No. 60 powder, 100 Gm. (25 oz. av.); Glycerin 25 Gm. (6½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 75 Gm. (18¾ oz. av. or 22 fluidounces) of alcohol. Moisten the powder with 35 Gm. (8¾ oz. av. or 9½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, and when the liquid in the percolator has disappeared from the surface gradually pour on a mixture of alcohol and water, made in the proportion of 3 parts of alcohol to 1 part of water (or, by measure, of 15 fluidounces of alcohol and 4 fluidounces of water), and continue the percolation until the cinchona is exhausted. Reserve the first 75 Ccm. (18 fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the same proportions as before, to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

Take of yellow cinchona-bark, in coarse powder, 1 pound; distilled water a sufficiency; rectified spirit 1 fluidounce. Macerate the cinchona-bark in 2 pints of the water for 24 hours, stirring frequently; then pack in a percolator and add more water, until 12 pints have been collected or until the water ceases to dissolve anything more. Evaporate the liquor at a temperature not exceeding 160° F. to a pint; then filter through paper, and continue the evaporation to 3 fluidounces or until the specific gravity of the liquid is at 1.200. When cold add the spirit gradually, constantly stirring. The specific gravity should be about 1.100.—Br.

The first formula is decidedly the better, and, though the addition of a small quantity of water to the mixture of alcohol and glycerin would yield an equally good preparation, the fluid extract remains practically unaltered. It is of a rich red-brown color, and if made of good bark contains all the alkaloids in their natural combination. Water alone will but partially exhaust cinchona-bark, and during the long-continued evaporation a portion of the alkaloids will become insoluble through the alteration of the tannin. On the other hand, a stronger alcohol will dissolve more cinchonic red, but secure the more thorough exhaustion of the alkaloids. The product of the second formula cannot represent in each fluidounce the virtues of the 4 ounces of bark used, and there must necessarily be a considerable waste of valuable material.

Medical Uses.—An advantage of this preparation is, that it contains in solution all the active principles of cinchona, and not merely one or the other of the alkaloids. As a tonic it may be given in the dose of ½ fluidrachm (Gm. 2). For securing the anti-periodic effects of cinchona it is eligible only in mild cases of periodical fever; in severer cases efficient doses of it would be too bulky.

EXTRACTUM COLCHICI RADICIS, U. S.—EXTRACT OF COLCHICUM-ROOT.

Extractum colchici aceticum, U. S. 1870, Br.—*Acetic extract of colchicum*, E.; *Extrait de colchique acétique*, Fr.; *Zeilosen-Essigextrakt*, G.

Preparation.—Colchicum-Root, in No. 60 powder, 100 parts (20 oz. av.); Acetic

Acid 35 parts (7 oz. av.); Water a sufficient quantity. Mix the acetic acid with 150 parts (30 oz. av. or 28 fluidounces) of water, and, having moistened the powder with 50 parts (10 oz. av. or 9½ fluidounces) of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then water, until the colchicum-root is exhausted. Evaporate the percolate in a porcelain vessel by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence. —*U. S.*

The corresponding preparation of the Br. P. is made like the extract, the formula of which is given below, the only difference consisting in the addition of 6 fluidounces of acetic acid to the bruised colchicum-tubers before the juice is expressed. The extract is of a brown color and bitter taste, and yields with water a rather turbid solution. The U. S. P. errs in directing it to be of pilular consistence, while the Br. P. is correct in stating it to be a soft extract; it is certainly softer than the next:

EXTRACTUM COLCHICI. *Br.*—Extract of colchicum, *E.*; Extrait de bulbe de colchique, *Fr.*; Zeitlosen-Extrakt, *G.*—Take of fresh colchicum-corms, deprived of their coats, 7 pounds. Crush the corms, press out the juice, allow the feculence to subside, and heat the clear liquor to 212° F.; then strain through flannel, and evaporate by a water-bath, at a temperature not exceeding 160° F., until the extract is of a suitable consistence for forming pills.—*Br.*

The extract of colchicum of the French Codex is prepared from the seeds with alcohol of 60 per cent.

Medical Uses.—These two extracts are convenient forms of colchicum for prescription in pills, and especially in those purgative pills which gouty patients commonly require. The *dose* of either is from ½ grain to 2 grains (Gm. 0.03–0.12), according to the British Pharmacopœia, but some German authorities state the dose at from ⅙ to ⅓ grain (Gm. 0.01–0.03).

EXTRACTUM COLCHICI RADICIS FLUIDUM, *U. S.*—FLUID EXTRACT OF COLCHICUM-ROOT.

Extrait liquide de bulbe de colchique, Fr.; *Flüssiges Zeitlosenknollen-Extrakt, G.*

Preparation.—Colchicum-Root, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts of alcohol with 1 part of water (or 50 fluidounces of alcohol with 20½ fluidounces of water), and, having moistened the powder with 35 Gm. (8½ oz. av. or 9½ fluidounces) of the mixture, pack it moderately in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the colchicum-root is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This fluid extract is of a deep brown-red color, keeps well, and fully represents the drug from which it is prepared. Made with diluted or a somewhat stronger alcohol, it likewise preserves its properties for a long time.

Medical Uses.—This preparation contains all the virtues of colchicum. *Dose*, from 2 to 8 minims (Gm. 0.10–0.50).

EXTRACTUM COLCHICI SEMINIS FLUIDUM, *U. S.*—FLUID EXTRACT OF COLCHICUM-SEED.

Extrait liquide de semence de colchique, Fr.; *Flüssiges Zeitlosensamen-Extrakt, G.*

Preparation.—Colchicum-Seed, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts of alcohol with 1 part of water (or 50 fluidounces of alcohol with 20½ fluidounces of water), and, having moistened the powder with 30 Gm. (7½ oz. av. or 8 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the per-

colator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the colchicum-seed is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The present menstruum is weaker in alcohol than heretofore; hence a much smaller amount of fixed oil is taken up by it and separates from the fluid extract on standing; the use of diluted alcohol would entirely obviate this, and such a change would be of no disadvantage, since the active principle is readily soluble in water and its preservation ensured by the glycerin and alcohol. As stated on page 483, the unbroken seeds may be completely deprived of their colchicine by a warm menstruum; and such a change seems desirable in view of the difficulty experienced in reducing the seeds to powder.

Medical Uses.—Like the preceding, this extract is a full representative of colchicum. *Dose*, from 2 to 8 minims (Gm. 0.10–0.50).

EXTRACTUM COLOCYNTHIDIS, *U. S.*, *P. G.*—EXTRACT OF COLOCYNTH.

Extractum colocynthidis alcoholicum.—*Extrait de coloquinte*, Fr.; *Koloquinten-Extrakt*, G.

Preparation.—Colocynth, dried and freed from the seeds, 100 parts (20 oz. av.); Diluted Alcohol a sufficient quantity. Reduce the colocynth to a coarse powder by grinding or bruising, and macerate it in 250 parts (50 oz. av. or 52 fluidounces) of diluted alcohol for 4 days, with occasional stirring; then express strongly and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour diluted alcohol upon it until the tincture and expressed liquid, mixed together, weigh 500 parts (100 oz. av. or 6¼ pints). Having recovered from the mixture 300 parts (60 oz. av. or about 4 pints) of alcohol by distillation, evaporate the residue to dryness by means of a water-bath. Lastly, reduce the dry mass to powder. Extract of colocynth should be kept in well-stopped bottles.—*U. S.*

This is the process of 1870, with slight modifications of manipulation, which are questionable improvements. For 48 troyounces of colocynth, equal to about 16 troyounces of pulp, 8 pints of diluted alcohol were considered to be not too large a quantity for the first maceration; and Klie (1878) found 4 pints to be requisite for the complete immersion of 15 troyounces of pulp, the powder being pressed down. The present formula orders only 3¼ pints of diluted alcohol for more than 18 troyounces of the pulp, which is entirely insufficient. Maceration and expression being considered necessary in the beginning, it would seem that the extract remaining in the press-cake could be more expeditiously obtained, and with a smaller amount of menstruum, by repeating the operation once or twice. This is the process of the German Pharmacopœia, which directs for 2 parts of colocynth, with the seeds, for the first maceration, 15 parts of alcohol spec. grav. .894, and for the second maceration 5 parts each of the same alcohol and of water. With some care colocynth may be treated at once by percolation, but owing to the spongy character of its tissues it is advisable to express the absorbed liquid with a good press as soon as the greater portion of the active matter is exhausted. When the extract is made on a large scale the removal of the seeds is a tedious operation, if not impossible. For this reason the colocynth is ground, care being taken not to crush the seeds, which would load the extract with much oily matter. Dr. Squibb (1867) obtained from very dry colocynth 20.6 per cent. of extract; the general yield from the commercial article is about 14 to 14.5 per cent. After completely removing the seeds, Procter (1867) had left, from 49 troyounces of colocynth, only 12 troyounces of pulp, which yielded 3¼ troyounces of extract, equal to 6.8 per cent., while G. H. C. Klie (1878) obtained 16 troyounces of pulp, and not over 6 troyounces, or 12.5 per cent., of extract. The pulp alone yields usually from 30 to 40 per cent., the seeds about 5 per cent., of extract, the latter being far less bitter than the former.

Off. Prep.—Extr. colocynthidis comp., *U. S.*

Medical Uses.—It is seldom used alone, but is an ingredient of the compound extract of colocynth. In Germany this extract is prescribed as a mild laxative in the *dose* of from ½ grain to 1 grain (Gm. 0.03 to 0.06), and as a drastic purgative in the *dose* of from 1½ to 2 grains (Gm. 0.1 to 0.3).

EXTRACTUM COLOCYNTHIDIS COMPOSITUM, U. S., Br.— COMPOUND EXTRACT OF COLOCYNTH.

Extrait de coloquinte composé, Fr.; Zusammengesetztes Koloquinten-Extrakt, G.

Preparation.—Extract of Colocynth 16 parts (8 oz. av.); Aloes 50 parts (25 oz. av.); Cardamom, in No. 60 powder, 6 parts (3 oz. av.); Resin of Scammony, in fine powder, 14 parts (7 oz. av.); Soap, dried and in coarse powder, 14 parts (7 oz. av.); Alcohol 10 parts (5 oz. av. or $5\frac{1}{8}$ fluidounces). Heat the aloes on a water-bath until it is completely melted; then add the alcohol, and, having stirred the mixture thoroughly, strain it through a fine sieve which has just been dipped into boiling water. To the strained mixture, contained in a suitable vessel, add the soap, extract of colocynth, and resin of scammony, and heat the mixture, at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous and a thread taken from the mass appears brittle when cool. Then withdraw the heat, thoroughly incorporate the cardamom with the mixture, and cover the vessel until the contents are cold. Finally, reduce the product to a fine powder. Compound extract of colocynth should be kept in well-stopped bottles.—*U. S.*

Take of colocynth-pulp 6 ounces; extract of Socotrine aloes 12 ounces; resin of scammony 4 ounces; hard soap, in powder, 3 ounces; cardamom-seeds, in fine powder, 1 ounce; proof spirit 1 gallon. Macerate the colocynth in the spirit for 4 days; press out the tincture and distil off the spirit; then add the aloes, scammony, and soap, and evaporate by a water-bath until the extract is of a suitable consistence for forming pills, adding the cardamoms toward the end of the process.—*Br.*

The first formula is preferable for directing a definite amount of the extract of colocynth, instead of the extract obtained from a definite weight of colocynth-pulp, which may vary considerably (see above). By mixing the ingredients in the state of fine powder a preparation uniform in appearance cannot be obtained. But by melting them together with the assistance of a little alcohol, and by subsequently drying and powdering, an unobjectionable compound extract is produced. It is, however, difficult to understand why the Pharmacopœia has introduced a new element of uncertainty in directing the use of commercial aloes, and straining it, instead of using *purified* aloes. The change in composition is thus shown:

1870: Extr. coloc. 13.33;	Aloe purif. 53.33;	Pulv. cardam. 6.67;	Res. scammon. 13.33;
1880: " " 14.0;	" commer. 50.0;	" " 6.0;	" " 14.0;
			Sapo 13.33 per cent.

Medical Uses.—As an efficient and safe purgative this compound, when well prepared, is not excelled by any other in cases of habitual *constipation* produced by torpor of the bowels. Calomel or rhubarb can be added to it to meet special indications, or, if it is disposed to gripe, extract of hyoseyamus will help to correct this tendency. The *dose* is from 5 to 20 grains (Gm. 0.30–1.30). This extract, as found in the shops, is often inert.

EXTRACTUM CONII ALCOHOLICUM, U. S.—ALCOHOLIC EXTRACT OF CONIUM.

Alcoholic extract of hemlock-fruit, E.; Extrait alcoolique de semence (fruit) de ciguë, Fr.; Spirituöses Schierlingsfrucht-Extrakt, G.

Preparation.—Conium, in No. 40 powder, 100 parts (20 oz. av.); Diluted Hydrochloric Acid 3 parts ($\frac{3}{8}$ oz. av. = $262\frac{1}{2}$ gr.); Glycerin, Diluted Alcohol, each a sufficient quantity. Moisten the powder with 30 parts (6 oz. av. or 6 $\frac{1}{2}$ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or until the conium is exhausted. Reserve the first 90 parts (18 oz. av. or 18 fluidounces) of the percolate, add the diluted hydrochloric acid to the remainder, and evaporate it, at a temperature not exceeding 50° C. (122° F.), to a soft extract; mix this with the reserved portion in a porcelain capsule, and evaporate at or below the before-mentioned temperature to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The extract formerly recognized under the above title was made from the leaves, and was of slight efficacy and variable strength. By using the green fruit a more reliable preparation is obtained, of which, however, the limits of variation of strength have not

been ascertained. The addition of hydrochloric acid is intended to prevent the volatilization of the conine. The yield is between 10 and 12 per cent.

EXTRACTUM CONII, Br. is the inspissated juice of the fresh herb, prepared in precisely the same manner as the corresponding inspissated juices of aconite and belladonna. The yield is 3 or 4 per cent.

Medical Uses.—The primary *dose*, of about 2 grains (Gm. 0.10), may be gradually increased until its operation becomes manifest.

EXTRACTUM CONII FLUIDUM, U. S.—FLUID EXTRACT OF CONIUM.

Extractum conii fructus fluidum, U. S. 1870.—*Fluid extract of hemlock-fruit, of conium-seed*, E.; *Extrait liquide de semence (fruit) de ciguë*, Fr.; *Flüssiges Schierlingsfrucht-Extrakt*, G.

Preparation.—Conium, in No. 40 powder, 100 Gm. (25 oz. av.); Diluted Hydrochloric Acid 3 Gm. ($\frac{3}{4}$ oz. av. = 328 grains); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 30 Gm. ($7\frac{1}{2}$ oz. av. or $7\frac{1}{2}$ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the conium is exhausted. Reserve the first 90 Cem. ($21\frac{1}{2}$ fluidounces) of the percolate, and, having added the diluted hydrochloric acid to the remainder, evaporate it, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

A fluid extract, prepared from the fully-developed green fruit of conium, is preferable to that from the leaves, which was formerly official. The hydrochloric acid is added to the portion to be evaporated for the purpose of preventing the evaporation of the readily volatile conine. The present formula differs from the former one mainly in omitting glycerin from the menstruum, which is not required. The fluid extract keeps well, is of a brown-green color, and has the peculiar odor of conium, and this is considerably increased on the addition of potassa.

Medical Uses.—It is a convenient form, and, next to the juice, the most reliable, for the administration of conium. *Dose*, from 2 to 6 minims (Gm. 0.10–0.40).

EXTRACTUM CORNUS FLUIDUM, U. S.—FLUID EXTRACT OF CORNUS.

Extractum cornus floridæ fluidum, U. S. 1870.—*Fluid extract of dogwood*, E.; *Extrait liquide de cornouiller à grandes fleurs*, Fr.; *Flüssiges Kornelrinden-Extrakt*, G.

Preparation.—Cornus, in No. 60 powder, 100 Gm. (25 oz. av.); Glycerin 20 Gm. (5 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 80 Gm. (20 oz. av. or $20\frac{3}{4}$ fluidounces) of diluted alcohol. Moisten the powder with 30 Gm. ($7\frac{1}{2}$ oz. av. or $7\frac{1}{2}$ fluidounces) of the mixture, and pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the cornus is exhausted. Reserve the first 85 Cem. ($20\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

This fluid extract is of a reddish-brown color, represents fully the virtues of the bark, and keeps well. The present menstruum is identical with that of 1870, but the process is an improvement over the former one.

Medical Uses.—This official preparation appears to be entirely superfluous. It may be given in the *dose* of a fluidrachm (Gm. 4) or more.

EXTRACTUM CUBEBÆ FLUIDUM, U. S.—FLUID EXTRACT OF CUBEB.

Extrait liquide de cubèbe, Fr.; *Flüssiges Kubeben-Extrakt*, G.

Preparation.—Cubeb, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 25 Gm. (64

oz. av. or 7½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cubeb is exhausted. Reserve the first 90 Cem. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This fluid extract should not be confounded with the oleoresin of the same drug, which was formerly recognized as fluid extract; it contains the medicinally active resin, together with most of the volatile oil, is of a dark-green color, and has the odor and taste of cubeb.

Medical Uses.—As a substitute for cubeb this preparation is of doubtful utility, except, perhaps, in chronic affections of the genito-urinary passages. *Dose*, from 10 to 30 minims (Gm. 0.60–2.00).

EXTRACTUM CYPRIPEDII FLUIDUM, *U. S.*—FLUID EXTRACT OF CYPRIPEDIUM.

Extrait liquide de cyripède de jaune, Fr.; *Flüssiges Gellifrauschuh-Extrakt*, G.

Preparation.—Cypripedium, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 35 Gm. (8¼ oz. av. or 10½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cypripedium is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

From what is known of the constituents of cypripedium, it is likely that a weaker alcohol would yield an equally efficient and permanent preparation. It is of a reddish-brown color, with the taste of the drug well marked.

Medical Uses.—*Dose*, from 10 to 20 minims (Gm. 0.60–1.30).

EXTRACTUM DIGITALIS, *U. S.*—EXTRACT OF DIGITALIS.

Extractum digitalis alcoholicum.—*Extrait alcoolique de digitale*, Fr.; *Fingerhut-Extrakt*, G.

Preparation.—Digitalis, recently dried and in No. 60 powder, 100 parts (20 oz. av.); Alcohol 200 parts (40 oz. av. or 47 fluidounces); Water 100 parts (20 oz. av. or 19 fluidounces); Glycerin, Diluted Alcohol, each a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 40 parts (8 oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the digitalis is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

In the selection of the menstruum this formula is an improvement on that of 1870, when alcohol followed by diluted alcohol was directed: the French Codex directs a weaker alcoholic solvent of 60 per cent. by volume. The yield is usually from 22 to 25 per cent. The extract is of a green-brown color, and with ordinary care retains a good consistence without having glycerin incorporated with it. *Extractum digitalis, P. G.*, is the inspissated juice, prepared like *Extractum belladonnæ*. It is brown, and its weight is equal to that of 3 or 4, or sometimes 5, per cent. of the fresh leaves and branches employed.

Medical Uses.—This extract is rarely used, and probably is less reliable than any other preparation of digitalis. *Dose*, ¼ grain (Gm. 0.01), and gradually increased.

EXTRACTUM DIGITALIS FLUIDUM, U. S.—FLUID EXTRACT OF DIGITALIS.

Extrait liquide de digitale, Fr.; Flüssiges Fingerhut-Extrakt, G.

Digitalis, recently dried and in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 35 Gm. (8½ oz. av. or 9½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the digitalis is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

Digitalis not being indigenous to North America, and the leaves varying in activity according to the locality of their growth, the directions of this and the preceding formula to employ recently-dried leaves cannot well be carried out. The present formula differs from that of 1870 mainly in omitting the glycerin and in using a menstruum stronger in alcohol. This is an improvement, and the precipitate which is formed on standing probably retains little or none of the active principles of the leaves. The fluid extract is of a green-brown color, and a fair representative of digitalis.

Medical Uses.—Its advantages over the tincture, and especially over the infusion, are not very apparent. The *dose* is 1 or 2 drops (Gm. 0.06–0.12).

EXTRACTUM DULCAMARÆ FLUIDUM, U. S.—FLUID EXTRACT OF DULCAMARA.

Fluid extract of bitter-sweet, E.; Extrait liquide de douce-amère, Fr.; Flüssiges Bittersüss-Extrakt, G.

Preparation.—Dulcamara, in No. 60 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 10½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the dulcamara is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

Glycerin, which was directed in 1870 as part of the menstruum, has been omitted, and the alcoholic strength of the finished preparation has been increased, which was scarcely necessary for the permanence of the fluid extract. It is of a deep-brown color, and on standing deposits a precipitate which probably contains none of the active principle.

EXTRACTUM DULCAMARÆ, U. S. 1870, which has been dismissed from the Pharmacopœia, was made with diluted alcohol, and may be prepared extemporaneously by evaporating the fluid extract; the twigs yield from 20 to 25 per cent. of extract.

Medical Uses.—This fluid extract probably contains all the active elements of dulcamara, and may be prescribed in the *dose* of a fluidrachm (Gm. 4), largely diluted and gradually increased.

EXTRACTUM ERGOTÆ, U. S.—EXTRACT OF ERGOT.

Extractum secalis cornuti, P. G.; Extractum hæmostaticum.—Extrait d'ergot de seigle, Fr.; Mutterkornextrakt, G.

Preparation.—Fluid Extract of Ergot 500 parts (5 oz. av.); to make 100 parts (1 oz. av.). Evaporate the fluid extract of ergot, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to 100 parts (1 oz. av.).—U. S.

Exhaust ergot 10 parts by maceration with cold water; evaporate the mixed infusions to 5 parts, add alcohol spec. grav. .894, 5 parts, shake well; after 3 days filter, and

evaporate to the consistence of an extract; treat this extract twice with its weight of alcohol, decant the liquid, and evaporate the residue to a thick extract.—*P. G.*

The first formula is based upon observations made by Dr. Squibb (*Proc. Amer. Phar. Assoc.*, 1873, p. 644) with fluid extract of ergot, *U. S. P.* 1860; this was prepared with diluted alcohol containing some acetic acid, and represented 5 per cent. more of ergot than the present fluid extract. 6 parts of the former yielded 1 part of extract, which was insoluble in cold alcohol, perfectly soluble in diluted alcohol, and easily soluble in water, with the exception of an insignificant residue which could easily be filtered out, the filtrate being of a garnet-red color. The above formula directs 5 parts of the present weaker fluid extract to yield 1 part of extract, or 20 per cent. more than was obtained by Dr. Squibb. Considering the variation of soluble matter in ergot (see below), the extract strictly prepared in accordance with the above directions may vary greatly in consistence. It is of a light-brown or reddish-brown color, having the behavior to solvents stated above; on being treated with an alkali the peculiar odor of ergot is strongly increased.

The extract resulting from the second formula is evidently intended to contain the active sclerotic acid in a more concentrated state. The concentrated infusion on being mixed with the quantity of alcohol stated yields a precipitate consisting mainly of inert salts and scleromucin; on treating the extract subsequently with alcohol coloring matters and alkaloidal salts are removed and the sclerotates left in the extract. The yield is about 14 per cent. By treating the concentrated infusion with alcohol, Hirsch (*Vergleichende Uebersicht*, 1883, p. 119) obtained from 8.66 to 20. and on an average 15, per cent. of extract.

ERGOTINUM.—Ergotin, *E., G.*; Ergotine, *Fr.*—According to Bonjean's process, the aqueous infusion of ergot is concentrated to a thin syrup; this is mixed with a large excess of alcohol—according to Charles (1878), as long as a precipitate is produced—and the filtrate evaporated; the yield is between 8 and 11 per cent. (See paper on ergotin by Prof. Diehl, read before the Kentucky Phar. Assoc., 1881.) The liquid should evidently contain less than 75 per cent. by volume of alcohol, in order to avoid the precipitation of the salts of sclerotic acid.

Medical Uses.—*Dose*, 3 to 15 grains (Gm. 0.20–1).

EXTRACTUM ERGOTÆ FLUIDUM, *U. S., Br.*—FLUID EXTRACT OF ERGOT.

Extrait liquide d'ergot de seigle, Fr.; Flüssiges Mutterkornextrakt, G.

Preparation.—Ergot, recently ground and in No. 60 powder, 100 Gm. (25 oz. av.): Diluted Hydrochloric Acid 6 Gm. (1½ oz. av.); Alcohol, Water, each a sufficient quantity: to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 4 parts of water (or, by measure, 10 fluidounces of alcohol and 11 fluidounces of water), and, having moistened the powder with 30 Gm. (7½ oz. av. or 7½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the ergot is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and, having added the diluted hydrochloric acid to the remainder, evaporate to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The menstruum used contains 46 per cent. by volume of absolute alcohol, and the resulting tincture must therefore be free from scleromucin and other less active principles, but contain all the sclerotates. The addition of hydrochloric acid to the portion to be evaporated, if not positively injurious, is of no advantage whatever. None of the alkaloids which are acknowledged to naturally exist in ergot are volatile, and the volatile so-called secaline—more properly trimethylamine—the presence of which in the fluid extract it was formerly intended to secure by the addition of acetic acid, is a product of decomposition, and probably does not contribute to the medicinal activity of this preparation. The presence of glycerin, which was ordered in 1870, is not necessary for preservation; its absence renders the fluid extract suitable for the preparation of a thick extract and of solutions adapted for hypodermic use.

The corresponding preparation of the *Br. P.* is equally efficient, and has the advantage of not containing any uncombined mineral acid. The following is the formula: Take of

ergot, in coarse powder, 1 pound; ether 1 pint or a sufficiency; distilled water $3\frac{1}{2}$ pints; rectified spirit 8 fluidounces. Shake the ether in a bottle with half a pint of the water, and after separation decant the ether. Place the ergot in a percolator, and free it from its oil by passing the washed ether slowly through it. Remove the marc, and digest it in 3 pints of the water at 160° F. for 12 hours. Press out, strain, and evaporate the liquor by the heat of a water-bath to 9 fluidounces; when cold add the spirit. Allow it to stand for an hour to coagulate, then filter. The product should measure 16 fluidounces.—*Br.*

The large quantity of fixed oil contained in ergot and liable to be displaced by an alcoholic menstruum is in this process first exhausted by ether, for which a light petroleum benzin may be advantageously substituted.

Medical Uses.—This preparation represents the totality of the active elements of ergot. In cases of *uterine inertia* it may be prescribed in the *dose* of half a fluidrachm to a fluidrachm (Gm. 2–4), repeated every 15 or 20 minutes. To counteract the effects of *spinal hyperæmia* the commencing dose should not be less than 2 drachms (Gm. 8), three times a day, and it may be increased to three, or even four, times that quantity.

EXTRACTUM ERYTHROXYLI FLUIDUM, *U. S.*—FLUID EXTRACT OF ERYTHROXYLON.

Extractum cocæ fluidum.—*Etrait liquide de coca.* Fr.; *Flüssiges Cocaeextrakt.* G.

Preparation.—Erythroxyton, in No. 30 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 45 Gm. (11 $\frac{1}{4}$ oz. av. or 11 $\frac{3}{4}$ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the erythroxyton is exhausted. Reserve the first 80 Ccm. (19 $\frac{1}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This fluid extract was recommended by Kennedy (1878) to be made with a mixture of 3 measures of alcohol to 1 of water, but experience has shown that with diluted alcohol an unobjectionable preparation is obtained. It is of a deep-brown or olive-brown color, and has the astringent bitter and slightly aromatic taste of the leaves.

Medical Uses.—This should be an active preparation of coca, but it may be suspected that its effects are modified by its alcoholic menstruum. The dose is stated to be from 1 to 4 fluidrachms (Gm. 4–16).

EXTRACTUM EUCALYPTI FLUIDUM, *U. S.*—FLUID EXTRACT OF EUCALYPTUS.

Etrait liquide d'eucalyptus, Fr.; *Flüssiges Eukalyptusextrakt,* G.

Preparation.—Eucalyptus, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8 $\frac{3}{4}$ oz. av. or 10 $\frac{1}{4}$ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the eucalyptus is exhausted. Reserve the first 85 Ccm. (20 $\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Alcohol is a good solvent for the valuable constituents of eucalyptus-leaves, but Mr. Alonzo Robbins found the fluid extract prepared with this menstruum to gradually deposit a moderate quantity of precipitate and a bulky greenish somewhat gelatinous matter, probably consisting of chlorophyll and waxy and fatty matter. A fluid extract made with a mixture of 3 parts of alcohol and 1 part of water remains free from the latter objection; this menstruum, being also sufficiently strong in alcohol for dissolving the medicinal principles, is therefore preferable. The fluid extract is greenish-brown, and has the characteristic odor and taste of the leaves.

Medical Uses.—This is probably the best form in which eucalyptus can be administered. *Dose*, 10 to 20 minims (Gm. 0.60–1.20).

EXTRACTUM EUONYMI, U. S.—EXTRACT OF EUONYMUS.

Extract of wahoo, E.; *Extrait d'écorce de fusain*, Fr.; *Spillbaumninden-Extrakt*, G.

Preparation.—Euonymus, in No. 30 powder, 100 parts (20 oz. av.); Glycerin, Diluted Alcohol, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 8½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the euonymus is exhausted. By means of a water-bath distill off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it, on a water-bath, to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The menstruum appears to be well chosen for extracting wahoo-bark. The extract is of a brown or yellowish-brown color.

Medical Uses.—Probably this preparation contains whatever virtues belong to euonymus. *Dose*, about 5 grains (Gm. 0.30).

EXTRACTUM EUPATORII FLUIDUM, U. S.—FLUID EXTRACT OF EUPATORIUM.

Fluid extract of boneset, E.; *Extrait liquide d'eupatoire perfoliée*, Fr.; *Flüssiges Durchwachsdesten-Extrakt*, G.

Preparation.—Eupatorium, in No. 30 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 10½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the eupatorium is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Although it has been prescribed to some extent, this fluid extract is now for the first time recognized by the Pharmacopœia. It is of a dark-greenish or brown-red color, and represents the virtues of the drug.

Medical Uses.—This preparation may be used to obtain the tonic effects of eupatorium, in the dose of a fluidrachm (Gm. 4).

EXTRACTUM FRANGULÆ FLUIDUM, U. S.—FLUID EXTRACT OF FRANGULA.

Extrait liquide d'écorce de bourdaine, Fr.; *Flüssiges Faulbaumninden-Extrakt*, G.

Preparation.—Frangula, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 1 part of alcohol with 2 parts of water (or, by measure, 25 fluidounces of alcohol and 41 fluidounces of water), and, having moistened the powder with 35 Gm. (8½ oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the frangula is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This is likewise newly introduced. The fluid extract has a dark brown-red color and the sweetish-bitter taste of the bark. Made from bark of a sufficient age, it appears to

fairly represent the drug, but experience must determine whether a somewhat stronger alcohol may not be a more suitable menstruum.

Medical Uses.—The action of this laxative appears to be very uncertain. The *dose* of it is variously stated at $\frac{1}{2}$ fluidrachm, and at half that quantity (Gm. 1–2).

EXTRACTUM GELSEMI FLUIDUM, U. S.—FLUID EXTRACT OF GELSEMIUM.

Extrait liquide de gelsemium, Fr.; Flüssiges Gelsemienextrakt, G.

Preparation.—Gelsemium, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 30 Gm. ($7\frac{1}{2}$ oz. av. or $8\frac{3}{4}$ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the gelsemium is exhausted. Reserve the first 90 Cem. ($21\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

Alcohol is well adapted for exhausting gelsemium. The fluid extract has a deep red-brown color and the strong odor and bitter taste of the drug. In 1870 the menstruum was alcohol sp. grav. .835, which furnished an unobjectionable preparation.

Medical Uses.—If used at all, for which there seems to be no necessity, great caution should be observed, on account of the profound and even fatal depression it has occasioned. The *dose* is from 5 to 10 minims (Gm. 0.30–0.60).

EXTRACTUM GENTIANÆ, U. S., Br., P. G.—EXTRACT OF GENTIAN.

Extrait de gentiane, Fr.; Enzianextrakt, G.

Preparation.—Gentian, in No. 20 powder, 100 parts (20 oz. av.); Water a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or $7\frac{3}{4}$ fluidounces) of water, and let it macerate for 48 hours; then pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the gentian. Reduce the liquid to three-fourths of its weight by boiling, and strain; then by means of a water-bath evaporate to a pilular consistence.—U. S.

The British Pharmacopœia alone directs boiling with water for exhausting gentian-root, while the United States, French, and German Pharmacopœias exhaust with cold water, the albumen being removed from the infusion by boiling. The long-continued boiling directed by the U. S. P. until one-fourth of the solution has evaporated is not necessary. Cold water is preferable for exhausting gentian, since it dissolves all of the bitter principle without taking up the whole of the pectin compounds, which enter into solution in hot water. An extract prepared with the latter has a gelatinous appearance, though not in the same degree as if made by prolonged boiling with water. The yield by cold water approaches, or sometimes exceeds, 30 per cent. of the weight of the dry root, and the yellowish-brown extract yields with water a nearly clear solution.

Medical Uses.—This extract contains all the virtues of gentian in a form convenient for administration. It is, however, most generally used as an excipient for other tonics, and especially for iron and quinia. The *dose* is from 3 to 10 grains (Gm. 0.16–0.60).

EXTRACTUM GENTIANÆ FLUIDUM, U. S.—FLUID EXTRACT OF GENTIAN.

Extrait liquide de gentiane, Fr.; Flüssiges Enzianextrakt, G.

Preparation.—Gentian, in No. 30 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 35 Gm. ($8\frac{3}{4}$ oz. av. or 9 fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the gentian is exhausted. Reserve the first 80 Cem. ($19\frac{1}{4}$ fluidounces) of the percolate. By means of a water-bath

distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The use of glycerin, directed in 1870, has very properly been abandoned without detriment to the preparation, which is of a dark yellowish-brown color and bitter taste. The bitter principle of gentian is perfectly soluble in water, but a certain amount of alcohol is necessary for preventing fermentation.

Medical Uses.—It may be employed for all the purposes of the bitter tonics, but it is seldom prescribed alone. It may be used to reinforce the tonic properties of the compound tincture of gentian and other liquid tonic preparations. *Dose*, $\frac{1}{2}$ fluidrachm (Gm. 2).

EXTRACTUM GERANII FLUIDUM, *U. S.*—FLUID EXTRACT OF GERANIUM.

Extrait liquide de géranium maculé, Fr.; *Flüssiges Fleckstorchschnabel-Extrakt*, G.

Preparation.—Geranium, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. ($2\frac{1}{2}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 90 Gm. ($22\frac{1}{2}$ oz. av. or $23\frac{1}{4}$ fluidounces) of diluted alcohol, and, having moistened the powder with 35 Gm. ($8\frac{3}{4}$ oz. av. or $8\frac{3}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the geranium is exhausted. Reserve the first 70 Ccm. ($16\frac{3}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

It is a dark reddish-brown fluid extract of a strongly astringent taste. Compared with the formula of 1870, the glycerin has been reduced to one-third, without, however, obviating partial gelatinization. For this reason Mr. A. Robbins suggests, in place of diluted alcohol, a menstruum composed of 3 parts of alcohol and 1 part of water.

Medical Uses.—Fluid extract of geranium is an excellent substitute for the liquid preparations of catechu and other simple astringents. *Dose*, from $\frac{1}{2}$ fluidrachm to 1 or 2 fluidrachms (Gm. 2–8).

EXTRACTUM GLYCYRRHIZÆ, *U. S.*—EXTRACT OF GLYCYRRHIZA.

Succus liquiritiæ, P. G.; *Extractum liquiritiæ*.—*Liquorice*, *Extract of liquorice*, E.; *Suc (jus) de réglisse*, *Sucre noir*, Fr.; *Lakriz*, *Lakrizensaft*, G.

The commercial extract of the root of *Glycyrrhiza glabra*, *Linné*.

Preparation.—Liquorice is prepared for commercial purposes in the southern portion of Europe and in this country. The fresh root is mostly employed, but the dried root will likewise answer the purpose. The root is crushed to a pulpy mass or broken into a coarse powder, and then boiled with water over a naked fire or by steam. The liquor is expressed, allowed to settle, and decanted, or, for the common qualities, together with the fine pulpy matter evaporated by boiling and continued stirring until the mass has attained the proper consistence to be rolled out into sticks of a certain weight, a portion of olive oil being used to prevent it from adhering to the hands and the table. The sticks are made of an adopted length and thickness, stamped with the initials or name of the manufacturer or of the town where the factory is located, and finally dried. Russian liquorice-root is likewise used in the manufacture of liquorice.

On exhausting the root with hot or cold water hygroscopic extracts are obtained, but on treating the root now with steam Delondre (1856) observed that a considerable amount of matter was dissolved, which, on evaporating the solution, was friable, without attracting moisture, and had a sweet taste without acidity. It is this substance, consisting of altered glycyrrhizin, together with the starch contained in the root, which gives firmness to the commercial extract. Previous to 1878 over 1,000,000 pounds of liquorice were annually imported into the United States. Since 1878 the quantity imported has varied between 692,919 and 874,044 pounds in 1881, and a considerable quantity is manufactured here.

Description.—Liquorice appears in commerce packed in boxes between layers of

laurel-leaves (*Laurus nobilis*, *Linne*) to prevent the sticks from adhering; in Southern Russia oak-leaves are used for the same purpose. Besides the liquorice of American manufacture, two principal varieties are distinguished in our commerce, the *Sicilian* and *Calabrian* or *Spanish*. The former is in thin sticks, $\frac{1}{4}$ to $\frac{3}{8}$ inch (6 to 9 Mm.) in diameter, of a dull-black color, frequently of an empyreumatic taste, and generally very impure. The latter variety is in larger sticks, $\frac{3}{8}$ to 1 inch (15 to 25 Mm.) in diameter, 6 to 6 $\frac{3}{4}$ inches (15 to 17 Cm.) long, black, and somewhat glossy externally, slightly flexible except at a low temperature, and breaking with a sharp conchoidal and shining fracture; some small cavities may usually be found in the interior. The products of the different manufacturers of this liquorice differ from one another not only in the size of the sticks, but often by marked differences in their odor and taste; while some specimens are almost purely sweet, others are persistently acrid and empyreumatic. For medicinal purposes liquorice should be almost devoid of acidity.

Placed in cold water, a portion of the liquorice is dissolved, but the residue retains the shape of the sticks; after the addition of a little ammonia to the water, Rump (1855) observed the liquid to become again colored, and again to acquire a sweet taste from dissolving fresh portions of glycyrrhizin. The amount soluble in cold water varies considerably, and reaches in the best brands about 70 to 75 per cent. of the dried liquorice, but the percentage is usually a little less than this. "Not less than 60 per cent. of the extract should be soluble in cold water."—*U. S.* "After drying 100 parts of liquorice at 100° C. (212° F.) it should weigh at least 83 parts. On exhausting air-dry liquorice with water of not over 50° C. (122° F.), the residue dried in a water-bath should not exceed 25 per cent., and when examined under the microscope should not show any starch-granules."—*P. G.*

Under the name of *Italian liquorice* an impure article in thin sticks is met with, and the so-called *refined liquorice* of the shops is in still thinner cylindrical and glossy pieces, likewise impure and readily attacked by insects. *Pontefract cakes* are small liquorice lozenges which are much used in England. *Corigliano* and *Barracco* are the foreign brands most esteemed in the United States; *Solazzi* juice is highly valued in England.

Constituents.—Liquorice contains glycyrrhizin, free (soluble in ammonia) and in combination with ammonia (soluble in cold water); also starch, modified by long boiling, sugar, a little acrid resinous matter, from 8.4 to 17 per cent. of moisture, and from 6 to 9 per cent. of ash. Madsen (1881) treated the concentrated aqueous solution of liquorice with cold alkaline solution of copper, ignited the precipitate, and calculated the sugar from the cupric oxide obtained; the amount varied between 11 and 15 per cent., which is probably too high. For estimating the gum, the infusion was precipitated by alcohol, the well-washed precipitate dissolved in water, this solution precipitated by cupric sulphate and soda, the precipitate washed with dilute soda, dissolved in hydrochloric acid, and this solution precipitated by alcohol; good liquorice yielded from 1.5 to 4.4 per cent. of arabin.

Impurities and Adulterations.—Fragments of vegetable tissue are generally present to some extent; shreds of copper are sometimes also met with, and result from careless scraping of the evaporating-pans. The fraudulent additions usually consist of farinaceous matters, gum, glucose, and mineral compounds; the latter are estimated in the ash. Starch may sometimes be seen in little lumps in the interior of the sticks, and if not altered by heat may be recognized by the microscope. Gum added fraudulently is detected in the precipitate which takes place on the addition of an equal bulk of alcohol to the cold aqueous solution (see above). Grape-sugar will cause the solution of liquorice in cold water to be of a lighter color; it may be estimated after removing gum by alcohol and glycyrrhizin by sulphuric acid.

EXTRACTUM GLYCYRRHIZÆ PURUM, *U. S.*—PURE EXTRACT OF GLYCYRRHIZA.

Extrait de réglisse, Fr.; *Süssholzextrakt*, G.

Preparation.—Glycyrrhiza, in No. 20 powder, 100 parts (20 oz. av.); Water of Ammonia 15 parts (3 oz. av. or 3 fluidounces); Distilled Water a sufficient quantity. Mix the water of ammonia with 300 parts (60 oz. av. or 57 $\frac{1}{2}$ fluidounces) of distilled water, and, having moistened the powder with 100 parts (20 oz. av. or 19 $\frac{1}{4}$ fluidounces) of the menstruum, let it macerate for 24 hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first, the remainder of the men-

struum, and then distilled water, until the glycyrrhiza is exhausted. Lastly, by means of a water-bath, evaporate the infusion to a pilular consistence.—*U. S.*

The ammonia is intended to dissolve any glycyrrhizin which may be present in the powdered root in the insoluble condition, and to prevent its becoming insoluble from the loss of ammonia during evaporation. The yield is from 16 to 20, or even 25, per cent. The extract is of a brown color and of a sweet taste; it is used for preparing *Mistura glycyrrhizæ composita*, *U. S.* It yields a clear solution with water, as does also the following:

Other Extracts of Liquorice.—EXTRACTUM GLYCYRRHIZÆ, *Br.*: EXTRACTUM LIQUIRITILÆ RADICIS, *P. G.* 1872. This extract is practically identical with that of the French Codex, except that the latter exhausts the root by displacement with distilled water at a temperature of 15° to 20° C. (59° to 68° F.); the following is the formula: Take of liquorice-root, in coarse powder, 1 pound; distilled water, 4 pints. Macerate the liquorice-root with 2 pints of the water for 12 hours, strain, and press; again macerate the pressed marc with the remainder of the water for 6 hours, strain, and press. Mix the strained liquors, heat them to 100° C. (212° F.), and strain through flannel; then evaporate by a water-bath until the extract is of a suitable consistence for forming pills.—*Br.*

SUCCUS LIQUIRITILÆ DEPURATUS, *P. G.* s. EXTRACTUM GLYCYRRHIZÆ DEPURATUM.—Purified liquorice, *E.*: Extrait de suc de réglisse, *Fr.*: Gereinigter Lakritz, *G.*—It is recognized by several European pharmacopœias, and is made by alternately placing layers of washed straw and broken liquorice in a soluble vessel and covering the material with cold water. As the water becomes saturated it is withdrawn through a faucet below, and replaced by fresh water until but little color and taste are imparted to it. The perfectly clear liquids are then evaporated to the consistence of an extract, which should yield a clear solution with water. The yield is 50 to 60 per cent. For convenience in dispensing, a concentrated solution of definite strength is often kept on hand. To remove the resinous matter, which imparts a disagreeable acid taste, Unge- witter (1875) suggests the digesting of the stick liquorice in strong alcohol and afterward exhausting it with cold water.

ELIXIR E SUCCO LIQUIRITILÆ, *P. G.* Purified liquorice 10 parts is dissolved in 30 parts of fennel-water; the solution is mixed with anisated spirit of ammonia 10 parts.

Off. Prep.—1. *Of pure extract of liquorice*: Confectio sennæ, Decoct. aloes comp., *Mistura sennæ* comp., Tinct. aloes, Troch. opii, *Br.* 2. *Of liquorice*: Pil. ferri iodidi, Tinct. aloes, Troch. cubebæ, Troch. glycyrr. et opii, *U. S.*

Medical Uses.—Extract of liquorice is lenitive and demulcent; it also excites the secretions of the fauces, and perhaps of the larynx. It is chiefly employed in irritable conditions of these parts, in *sore throat*, *laryngitis*, and *bronchitis*. It may be conveniently used by allowing small fragments of it to dissolve in the mouth, or by adding it to the various syrups, lozenges, and mixtures appropriate to these objects. It sometimes appears to prevent *flatulence* depending upon fermentation of the food, for which purpose a piece as large as a grain of wheat may be taken after meals. "Pure extract of liquorice" (*U. S. P.* 1880) is still more appropriate to the purposes designated than the ordinary extract.

EXTRACTUM GLYCYRRHIZÆ FLUIDUM.—FLUID EXTRACT OF GLYCYRRHIZA.

Extractum glycyrrhizæ liquidum, *Br. Add.*—*Liquid extract of liquorice-root*, *E.*; *Extrait liquide de réglisse*, *Fr.*; *Flüssiges Süßholz-Extrakt*, *G.*

Preparation.—Glycyrrhiza, in No. 40 powder, 100 Gm. (25 oz. av.); Water of Ammonia, Diluted Alcohol, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix 3 parts (1 oz. av. or 1 fluidounce) of water of ammonia with 97 parts (32½ oz. av. or 33½ fluidounces) of diluted alcohol, and, having moistened the powder with 35 Gm. (8½ oz. av. or 9 fluidounces) of the mixture, pack it firmly in a cylindrical glass percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the glycyrrhiza is exhausted. Reserve the first 75 Cem. (18 fluidounces) of the percolate, and, having added 3 Gm. (½ oz. av. or 6 fluidrachms) of water of ammonia to the remainder, evaporate to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

Take of liquorice-root, in coarse powder, 1 pound; distilled water 4 pints. Macerate the liquorice-root with 2 pints of the water for 12 hours, strain, and press; again macerate the pressed marc with the remainder of the water for 6 hours, strain, and press. Mix

the strained liquors, heat them to 212° F., and strain through flannel; then evaporate by a water-bath until it has acquired, when cold, a specific gravity of 1.160; add to this one-eighth of its volume of rectified spirit; let the mixture stand for 12 hours, and filter.—*Br. Add.*

Both formulas yield fluid extracts containing the peculiar sweet taste of the liquorice-root. Prof. Remington (1878) suggested a menstruum composed of alcohol 4 fluidounces, glycerin 3 fluidounces, water 8 fluidounces, and stronger ammonia-water 1 fluidounce; this, even without the glycerin, appears to be preferable to that of the U. S. P., as being less alcoholic. The ammonia serves to dissolve any glycyrrhizin which may have been present in the insoluble condition; the fluid extract should be devoid of ammoniacal odor, and should have a very sweet taste, without bitterness. The preparation was recommended by Joseph Harrop (1869) for disguising the bitter taste of quinine.

AROMATIC ELIXIR OF LIQUORICE-ROOT. Dissolve oil of cloves 10 minims, oil of cinnamon 5 minims, and oil of nutmegs 12 minims in alcohol 4 fluidounces, and add syrup 6 fluidounces, fluid extract of liquorice-root 2 fluidounces, and water 4 fluidounces (Remington, 1878).

Medical Uses.—The fluid extract of liquorice-root is a very agreeable substitute for the simple extract of liquorice in flavoring cough medicines and concealing acrid tastes. The aromatic elixir is too stimulating to be used in the former, but may be used advantageously in the latter, manner.

EXTRACTUM GOSSYPH RADICIS FLUIDUM, U. S.—FLUID EXTRACT OF COTTON-ROOT.

Extrait liquide d'écorce de cotonnier, Fr.; Flüssiges Baumwollwurzel-Extrakt, G.

Preparation.—Cotton-Root, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 35 Gm. (8½ oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 65 Gm. (16¼ oz. av. or 19 fluidounces) of alcohol, and, having moistened the powder with 50 Gm. (12½ oz. av. or 13½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, and when the liquid in the percolator has disappeared from the surface gradually pour on alcohol, and continue the percolation until the cotton-root is exhausted. Reserve the first 70 Ccm. (16½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Fresh or recently-dried bark appears to yield a more effectual preparation than old bark. The fluid extract has a bright brownish-red color, but, like that of 1870, it will gelatinize, though not to the same extent. Mr. A. Robbins (1883) considers this due to the large amount of glycerin, and proposes to reduce it from 35 to 20 per cent., when the preparation will deposit only a moderate precipitate, and retain its red color without showing any signs of gelatinization. Prof. J. U. Lloyd (1876) proposed to use a mixture of 10 fluidounces of alcohol and 3 each of glycerin and water, and finish percolation with a menstruum composed of 10 fluidounces of alcohol and 6 of water.

Medical Uses.—It is used chiefly as a substitute for ergot, as an oxytocic and emmenagogue, and may be given in the *dose* of ½ fluidrachm (Gm. 2) or more.

EXTRACTUM GRINDELIAE FLUIDUM, U. S.—FLUID EXTRACT OF GRINDELIA.

Extrait liquide de grindélia, Fr.; Flüssiges Grindeliextrakt, G.

Preparation.—Grindelia, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol and 10 fluidounces of water), and, having moistened the powder with 30 Gm. (7½ oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the grindelia is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and

evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This fluid extract is of a brown-green color, but it does not appear to be as perfect a preparation as is desirable. In the previous editions of this work we suggested strong alcohol as the proper menstruum, which has yielded an unobjectionable fluid extract of a rich green color; the observations of Mr. A. Robbins (1883) coincide with this experience. The active principles are, most likely, volatile oil and resin, and these require alcohol for solution.

Dose, from 10 to 20 minims (Gm. 0.60–1.20).

EXTRACTUM GUARANÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF GUARANA.

Extrait liquide de guarana, Fr.; *Flüssiges Guaranaextrakt*, G.

Preparation.—Guarana, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 20 Gm. (5 oz. av. or 5½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the guarana is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate. By means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

A fluid extract of guarana has been in use for a number of years, but in the endeavor to obtain it as little alcoholic as possible many of the preparations formerly used gradually formed heavy deposits. This may be obviated by increasing the alcoholic strength; but Mr. A. Robbins (1883) has found a menstruum consisting of 2 parts by weight of alcohol and 1 part of water to be sufficiently strong for this purpose. Mr. J. H. Feemster (*Proc. Amer. Phar. Assoc.*, 1882, p. 570) recommends a mixture made of 8 parts by measure of alcohol and 4 parts each of glycerin and water as being free from the objections stated above. The fluid extract is of a deep red-brown color and has an astringent and bitter taste. The commercial fluid extract was found by E. Hosack (1883) to contain between 1.10 and 1.68 per cent. of caffeine, or one-third to one-fourth the amount present in guarana.

Dose, from 10 to 20 minims (Gm. 0.60–1.20) and upward.

EXTRACTUM HÆMATOXYLI, *U. S.*, *Br.*—HÆMATOXYLON.

Extractum ligni campechiani.—*Extract of logwood*, E.; *Extrait de bois de Campêche*, Fr.; *Campecheholz-Extrakt*, G.

Preparation.—Hæmatoxylon, rasped, 100 parts (1 pound); Water, 1000 parts (10 pounds). Macerate the hæmatoxylon with the water for 48 hours. Then boil, avoiding the use of metallic vessels, until one-half of the water has evaporated; strain the decoction while hot, and evaporate to dryness.—*U. S.*

The present process has been somewhat altered, so as to correspond with that of the British Pharmacopœia, which authority orders distilled water, maceration for 24 hours, boiling to one-half, and finally evaporation by a water-bath, stirring with a wooden spatula. The yield is about 12 per cent., occasionally as low as 6 per cent. The extract is not hygroscopic; it is of a red-brown color and a sweet afterward astringent taste. It yields with water a red and almost clear solution. It is prepared on a large scale for uses in the arts. (For composition compare HÆMATOXYLON.)

Medical Uses.—The extract has the medicinal qualities of the wood, and does not lose them by keeping. It may be administered in *doses* of 10 grains (Gm. 0.60) or more, and in solution rather than in pills, which in time grow very hard.

EXTRACTUM HAMAMELIDIS FLUIDUM, U. S.—FLUID EXTRACT OF HAMAMELIS.*Extrait liquide de hamamélis, Fr.; Flüssiges Hamamelisextrakt, G.*

Preparation.—Hamamelis, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 1 part of alcohol with 2 parts of water (or, by measure, 25 fluidounces of alcohol with 41 fluidounces of water), and, having moistened the powder with 35 Gm. (8 $\frac{3}{4}$ oz. av. or 8 $\frac{3}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the hamamelis is exhausted. Reserve the first 85 Ccm. (20 $\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This fluid extract appears for the first time in the Pharmacopœia. It is of a brown color, and has the astringent and bitter taste of the leaves. The substitution of glycerin for a portion of the water will probably give a better menstruum and yield a more permanent preparation.

Dose, from 10 to 20 minims (Gm. 0.60–1.20).

EXTRACTUM HYDRASTIS FLUIDUM, U. S.—FLUID EXTRACT OF HYDRASTIS.*Extrait liquide de hydrastis, Fr.; Flüssiges Hydrastisextrakt, G.*

Preparation.—Hydrastis, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 30 Gm. (7 $\frac{1}{2}$ oz. av. or 8 $\frac{1}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the hydrastis is exhausted. Reserve the first 85 Ccm. (20 $\frac{1}{2}$ fluidounces) of the percolate. By means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The fluid extract has a deep brown-yellow color and the strongly bitter taste of the root. The present menstruum is more alcoholic than that ordered by the U. S. P. 1870, and contains no glycerin; the addition of a small quantity of the latter appears to be of advantage.

Medical Uses.—This is a convenient and efficient form of the medicine. *Dose*, a fluidrachm (Gm. 4), two or three times a day.

EXTRACTUM HYOSCYAMI ALCOHOLICUM, U. S., Br.—ALCOHOLIC EXTRACT OF HYOSCYAMUS.*Extrait alcoolique de feuilles de jusquiame, Fr.; Spirituöses Bilsenkrout-Extrakt, G.*

Preparation.—Hyoscyamus, recently dried and in No. 60 powder, 100 parts (20 oz. av.); Alcohol 200 parts (40 oz. av. or 47 fluidounces); Water 100 parts (20 oz. av. or 19 $\frac{1}{4}$ fluidounces); Diluted Alcohol a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 40 parts (8 oz. av. or 8 $\frac{1}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the hyoscyamus is exhausted. Reserve the first 90 parts (18 oz. av. or about 18 fluidounces) of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; mix this with the reserved

portion, and evaporate, at or below the before-mentioned temperature, to a pilular consistence.—*U. S.*

A stronger alcohol is now directed than in 1870, when the proportion was 2 measures of alcohol sp. gr. .835 to 1 measure of water. The present menstruum is somewhat stronger than that of the French Codex, which is alcohol of 60 per cent. by volume. The extract has a green-brown color and the heavy odor of hyoscyamus. The leaves yield from 20 to 26 per cent. of extract, the seed about 16 per cent.; the latter extract is used to some extent in Europe.

EXTRACTUM HYOSCYAMI, *Br., P. G.*, is the inspissated juice of the fresh leaves and branches prepared like the inspissated juices of other narcotic herbs. The yield varies from 2.5 to 3.5 or 4 per cent. The color of the extract is brown-green (*Br.*) or greenish-brown (*P. G.*).

The crystals observed in old extracts, according to Attfield (1862), are potassium nitrate.

Medical Uses.—This preparation, like the former simple extract, is one of the most variable in strength of all narcotic extracts. Its minimum *dose*, of 2 grains (*Gm.* 0.10), should be rapidly increased until the characteristic effects of the medicine are produced.

EXTRACTUM HYOSCYAMI FLUIDUM, *U. S.*—FLUID EXTRACT OF HYOSCYAMUS.

Extrait liquide de jusquiame, Fr.; Flüssiges Bilsenkraut-Extrakt, G.

Preparation.—Hyoscyamus, in No. 60 powder, 100 *Gm.* (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 *Ccm.* (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 40 *Gm.* (10 oz. av. or 11 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the hyoscyamus is exhausted. Reserve the first 90 *Ccm.* (or 21½ fluidounces) of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 *Ccm.* (24 fluidounces).—*U. S.*

Glycerin, which formed part of the menstruum in 1870, has now been omitted and the alcohol increased in strength. The fluid extract is of a deep green-brown color, has the heavy odor of the drug, and keeps well.

Medical Uses.—The fluid extract is a good representative of hyoscyamus, and may be prescribed in *doses* of from 5 to 10 minims (*Gm.* 0.30–0.60), and increased if necessary.

EXTRACTUM IPECACUANHÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF IPECAC.

Extrait liquide d'ipécacuanha, Fr.; Flüssiges Ipecacuanha-Extrakt, G.

Preparation.—Ipecac, in No. 80 powder, 100 *Gm.* (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 *Ccm.* (24 fluidounces). Moisten the powder with 35 *Gm.* (8¼ oz. av. or 10½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed until the ipecac is exhausted. By means of a water-bath distil off the alcohol from the tincture until the residue measures 50 *Ccm.* (12 fluidounces), and add to it 100 *Ccm.* (24 fluidounces) of water. Evaporate the mixture to 75 *Ccm.* (18 fluidounces), let cool, and filter. Wash the precipitated resin upon the filter with water until the latter passes through tasteless, evaporate the filtrate and washings to 50 *Ccm.* (12 fluidounces), allow to cool, and add enough alcohol to make the fluid extract measure 100 *Ccm.* (24 fluidounces).—*U. S.*

This fluid extract offers peculiar difficulties if the preparation is to be completely soluble in an aqueous menstruum; hence numerous papers on this subject have appeared in American journals during the last twenty years, and the pharmacopœial formula has been altered in each edition, the present one being similar to that of 1860, but contains no

acetic acid. The difficulty arises from a compound erroneously called resin, but which we believe is a decomposition-product of the peculiar pectin compound of the root, perhaps associated with some coloring matter. These constituents vary to some extent, as is indicated already by the color and other physical properties of the drug, and while one sample of the latter may yield a fluid extract having the above-mentioned desirable quality, another may give more or less different results. In our experience, heat is one of the chief causes of the changes produced in this inert principle. During the first evaporation ordered by the pharmacopœial formula the full heat of a water-bath may be used; the liquid should then be cooled, if possible, to near 5° C. (41° F.), and after several hours filtered, when the filtrate should be concentrated at a moderate heat. The concentrated aqueous liquid is preserved against decomposition by alcohol; the Pharmacopœia of 1860 ordered glycerin, which will answer the purpose equally well. It will be observed that in the hands of the apothecary the conditions named are best carried out with operations upon a moderate quantity of the root.

Off. Prep.—Syrupus ipecacuanhæ, Tinctura ipecacuanhæ et opii, Vinum ipecacuanhæ, U. S.

Medical Uses.—Fluid extract of ipecacuanha is a convenient addition to expectorant mixtures, but hardly as much so as the syrup, to the preparation of which, indeed, it is essential. The *dose*, as an emetic, is about 20 or 30 minims (Gm. 1.20–2.00); as an expectorant, 5 minims (Gm. 0.30).

EXTRACTUM IRIDIS, U. S.—EXTRACT OF IRIS.

Extract of blue flag, E.; *Extrait d'iris varié*, Fr.; *Schwertel-extrakt*, G.

Preparation.—Iris, in No. 60 powder, 100 parts (20 oz. av.); Alcohol 225 parts (45 oz. av. or 52½ fluidounces); Water 75 parts (15 oz. av. or 14½ fluidounces); Diluted Alcohol a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 40 parts (8 oz. av. or 8¾ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the iris is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it, on a water-bath, to a pilular consistence.—U. S.

From what is known of the constituents of the drug, the menstruum should be efficient for extracting the active constituents. The extract is of a dark-brown color.

Dose, 2 or 3 grains (Gm. 0.12–0.20).

EXTRACTUM IRIDIS FLUIDUM, U. S.—FLUID EXTRACT OF IRIS.

Fluid extract of blue flag, E.; *Extrait liquide d'iris varié*, Fr.; *Flüssiges Schwertel-extrakt*, G.

Preparation.—Iris, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (24 oz. av.). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 40 Gm. (10 oz. av. or 11 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the iris is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder, on a water-bath, to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

The menstruum used is the same as for the preceding preparation. The fluid extract is of a deep red-brown color. Using alcohol for exhausting the drug, W. E. Jenks (1881) obtained a dark reddish-brown *oleoresin* of a thick viscid consistence and of a peculiar odor; by dissolving this in ether, filtering, and evaporating, it became comparatively free from astringency.

Dose, from 10 to 20 minims (Gm. 0.60–1.20).

EXTRACTUM JALAPÆ, Br.—EXTRACT OF JALAP.*Extrait de jalap, Fr. ; Jalapen-Extrakt, G.*

Preparation.—Jalap, in coarse powder, 1 pound; Rectified Spirit 4 pints; Distilled Water 1 gallon. Macerate the jalap in the spirit for 7 days, press out the tincture, then filter, and distil off the spirit, leaving a soft extract. Again macerate the residual jalap in the water for 4 hours, express, strain through flannel, and evaporate by a water-bath to a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F. until it has acquired a suitable consistence for forming pills.—*Br.*

No advantage whatever results from treating jalap with water after it has been exhausted by alcohol. 240 grains of such an aqueous extract were taken by A. B. Taylor (1864) in the course of 8 hours without producing any noticeable effect. Alcohol alone will yield between 12 and 18 or 22 per cent. of active extract, and cold water will subsequently extract 30 to 35 per cent. of inert matter, with which the official extract is uselessly diluted and encumbered. The supposed advantage is due to an erroneous conception of the statement that the aqueous extract was possessed of mild purgative and diuretic properties; this statement is correct as far as it applies to that portion of the aqueous extract soluble in alcohol, or, what is the same thing, to the aqueous extract of the alcoholic extract. Exhaustion with alcohol of about 70 per cent. would yield a much more efficient extract, but considerably less, and the dose would have to be correspondingly smaller. The *abstract of jalap* admitted into the U. S. P. 1880 fully represents the above extract in activity and dose, and does not form a tough mass like the latter; but the watery washing obtained in the preparation of resin of jalap when evaporated to the consistence of an extract would serve a useful purpose in the treatment of children and weak adults.

Medical Uses.—This preparation contains all the virtues of jalap in about half the bulk, and may be substituted for it in all prescriptions. The *dose* is from 10 to 20 grains (Gm. 0.60–1.30).

EXTRACTUM JUGLANDIS, U. S.—EXTRACT OF JUGLANS.*Extract of butternut, E.; Extrait d'écorce de noyer gris, Fr.; Butternussrinden-Extrakt, G.*

Preparation.—Juglans, in No. 30 powder, 100 parts (20 oz. av.); Glycerin, Alcohol, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 9½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 300 parts (60 oz. av. or about 4 pints) of tincture are obtained or the juglans is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The Pharmacopœia very properly discarded the use of water for exhausting butternut-bark, and avoids the temperature of boiling water, by which some of the nucin is volatilized; but it has not profited from the results obtained by B. F. Moise, Jr. (*Am. Jour. Pharm.*, 1881, p. 153; *Proc. Am. Ph. A.*, 1881, p. 71), who distinctly states that the extract prepared with *diluted* alcohol is more efficient than that prepared with alcohol, and that the latter menstruum exhausts so much fixed oil that the extract retains a plastic consistency and does not adhere to the jar or spatula; the Pharmacopœia therefore errs also in ordering an admixture of glycerin. The yield is from 12 to 15 per cent.; the extract is of a blackish-brown color and bitter taste.

Medical Uses.—It is a mild cathartic in the dose of 20 or 30 grains (Gm. 1.30–2), and is said to be peculiarly appropriate for relieving habitual costiveness.

EXTRACTUM KRAMERLÆ, U. S., Br.—EXTRACT OF KRAMERIA.*Extractum ratanhæ.—Extract of rhatany, E.; Extrait de ratanhia, Fr.; Ratanha-Extrakt, G.*

Preparation.—Krameria, in No. 40 powder, 100 parts (20 oz. av.); Water a sufficient quantity. Moisten the powder with 30 parts (6 oz. av. or 5½ fluidounces) of water, pack it in a conical glass percolator, and gradually pour water upon it until the

infusion passes but slightly imbued with the astringency of the krameria. Heat the liquid to the boiling-point, strain, and by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), evaporate to dryness.—*U. S.*

The processes of the other pharmacopœias are practically identical with this, but the *Br. P.* and *Fr. Cod.* order distilled in place of common water.

It is important that the root be exhausted with *cold* water. Hot water will yield about 5 or 6 per cent. more extract, which, however, is but incompletely soluble in water, while the official extract yields a somewhat turbid solution with warm water, but a clear solution in the presence of sugar. The amount of extract obtainable depends on the size and the variety of rhatany-root used, the woody part of which contains but little soluble matter. The smaller branches of Peruvian rhatany yield about 12 per cent. of *dry* extract, but the thick main root yields only 5 or 6 per cent.; Savanilla and Para rhatany give a larger yield, about 12 to 15 per cent. The extract is of a red-brown color, glossy, resembling kino in appearance, and is not hygroscopic. Iron utensils must not be used in its preparation.

Off. Prep.—Trochisci krameriæ, *U. S.*

Medical Uses.—This extract is a convenient form of krameria in nearly all of the cases for which that medicine is appropriate. The *dose* is from 5 to 20 grains (Gm. 0.30–1.30), the smaller dose being frequently repeated.

EXTRACTUM KRAMERIE FLUIDUM, *U. S.*—FLUID EXTRACT OF KRAMERIA.

Fluid extract of rhatany, E.; Extrait liquide de ratanhia, Fr.; Flüssiges Ratanha-Extrakt, G.

Preparation.—Krameria, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 20 Gm. (5 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 80 Gm. (20 oz. av. or 20½ fluidounces) of diluted alcohol, and, having moistened the powder with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, pack it firmly in a cylindrical glass percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the krameria is exhausted. Reserve the first 70 Ccm. (16½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

With the exception of a very slight reduction of the glycerin, the present preparation is identical with that of 1870; according to Mr. A. Robbins, the glycerin may with advantage be reduced to one-half the present quantity, the fluid extract remaining thinner and equally free from precipitate. It is of a deep brownish-red color and strongly astringent taste.

Off. Prep.—Syrupus krameriæ, *U. S.*

Medical Uses.—It has the advantage over the tincture of being more astringent and less stimulant. *Dose*, ½ fluidrachm (Gm. 2).

EXTRACTUM LACTUCÆ, *Br.*—EXTRACT OF LETTUCE.

Extractum lactucæ virosæ; Thridacium.—Extrait de feuilles de laitue vireuse, Fr.; Gift-lattich-Extrakt, G.

Preparation.—The formula of the British Pharmacopœia is identical with that for the inspissated juices of the other narcotic herbs (see page 613). The extract contains the chlorophyll and is incompletely soluble in water. The French Codex directs the removal of the chlorophyll and albumen, and obtains an extract of a dark-brown color which yields with water a somewhat turbid solution. The yield is about 3 or 4 per cent.

EXTRAIT DE LAITUE, THRIDACE. *F. Cod.*, is made in the same manner from the cortical portion of the stem of cultivated lettuce, and is sometimes called *French lactucarium*; the yield is about 1½ per cent.

Medical Uses.—Like all the medicinal preparations of lettuce, it is an extremely feeble hypnotic. *Dose*, 5 or more grains (Gm. 0.30).

EXTRACTUM LACTUCARII FLUIDUM, U. S.—FLUID EXTRACT OF LACTUCARIUM.*Extrait liquide de lactucarium, Fr. ; Flüssiges Lactucarium-Extrakt, G.*

Preparation.—Lactucarium, in coarse pieces, 100 Gm. (6½ oz. av.); Ether 100 Gm. (6½ oz. av. or 8 fluidounces); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (6 fluidounces). Add the lactucarium to the ether contained in a tared flask having the capacity of 600 Ccm. (36 fluidounces), and let it macerate for 24 hours; then add 300 Gm. (18½ oz. av. or 18 fluidounces) of water, and shake the mixture well. Fit a bent glass tube into the neck of the flask, and, having immersed the flask in hot water, recover the ether by distillation. When all the ether has distilled over remove the tube, and, after thoroughly shaking the contents of the flask, continue the heat for half an hour. Let the mixture cool, add 100 Gm. (6½ oz. av. or 7½ fluidounces) of alcohol and enough water to make the whole mixture weigh 500 Gm. (31½ oz. av.); after maceration for 24 hours, with occasional agitation, express and filter the liquid. Return the dregs to the flask, and macerate them with 200 Gm. (12½ oz. av. or 12 fluidounces) of a mixture of alcohol and water made in the proportion of 1 part (4 fluidounces) of alcohol to 3 parts (10 fluidounces) of water; repeat the maceration two or three times successively with fresh portions of the mixture until the dregs are tasteless or nearly so. Mix, and filter the liquids thus obtained, and concentrate them, by means of a water-bath (the first expressed liquid by itself), until the combined weight of the liquids is 60 Gm. (3¾ oz. av.); mix the liquids, add 40 Gm. (2½ oz. av. or 3 fluidounces) of alcohol, and let the mixture cool in the evaporating vessel, stirring the mixture frequently, and during the intervals keeping the vessel well covered. When cool, add enough alcohol to make the mixture weigh 100 Gm. (6½ oz. av.); transfer the liquid to a flask, and add enough water to make the mixture measure 100 Ccm. (6 fluidounces), using the water so required to rinse the evaporating vessel. Shake the mixture occasionally during several hours, and frequently if a portion of the precipitate is found to be tenacious, and when a uniform mixture results set it aside for 24 hours, so that any precipitate formed may subside. Decant the clear liquid, transfer the precipitate to a filter, and, after thoroughly draining it into the decanted liquid, wash it with a mixture of alcohol and water made in the proportion of 3 parts (or 10 measures) of alcohol to 4 parts (11 measures) of water, until the washings pass tasteless. Concentrate the washings, by evaporation, to a syrupy consistence, mix with the decanted liquid, and add enough of the last-named mixture of alcohol and water to make the whole measure 100 Ccm. (24 fluidounces). Lastly, after 24 hours, and having meanwhile shaken the fluid extract occasionally, filter it through paper.—*U. S.*

This elaborate process for a preparation of limited importance yields a brown fluid extract which is miscible with watery liquids without turbidity. Ether dissolves the lactucerin and caoutchouc, which on the distillation of the ether in the presence of water are left in incoherent, crummy particles, from which the bitter principles may be more readily extracted than from the lactucarium. A much simpler process, accomplishing the same end, was proposed by Lemberger (1875), benzin being used in place of ether, and the solution containing only inert principles being decanted; modified so as to correspond with the pharmacopœial fluid extract, the formula is as follows: Beat thoroughly 6½ oz. av. of lactucarium, agitate it for 24 hours with 12 fluidounces of petroleum benzin; decant the liquid, and when the lactucarium is dry rub it with an equal bulk of clean sand; introduce the mixture into a percolator upon a layer of sand; macerate it with a menstruum composed of 10 measures of alcohol and 11 measures of water, and exhaust by percolation, reserving the first 4 fluidounces; evaporate the remaining tincture, dissolve in the reserved portion, and add sufficient menstruum to obtain 6 fluidounces.

Off. Prep.—Syrupus lactucarii, *U. S.**Dose*, a fluidrachm, more or less (Gm. 4).**EXTRACTUM LEPTANDRÆ, U. S.—EXTRACT OF LEPTANDRA.***Extrait de leptandra, Fr. ; Leptandraextrakt, G.*

Preparation.—Leptandra, in No. 40 powder, 100 parts (20 oz. av.); Alcohol 200 parts (40 oz. av. or 47 fluidounces); Water 100 parts (20 oz. av. or 19½ fluidounces); Glycerin, Diluted Alcohol, each a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with 40 parts (8 oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate

the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the leptandra is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

This extract is evidently intended to take the place of the so-called leptandrin of commerce, which is of variable composition. By simply evaporating a tincture of leptandra it is extremely difficult to obtain a pulverizable extract, as pointed out by Dr. Greve and by Prof. Lloyd (1880), owing to the large amount of glucose present; the incorporation of glycerin, though not objectionable, is scarcely required. The yield is about 10 per cent. The extract is of a blackish-brown color, and is partly soluble in water, yielding a dark-brown, very bitter solution.

Dose, 2 to 4 grains (Gm. 0.12–0.24).

EXTRACTUM LEPTANDRÆ FLUIDUM, U. S.—FLUID EXTRACT OF LEPTANDRA.

Extrait liquide de leptandra, Fr.; *Flüssiges Leptandraextrakt*, G.

Preparation.—Leptandra, in No. 60 powder, 100 Gm. (25 oz. av.); Glycerin 15 Gm. (3½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 85 Gm. (21¼ oz. av. or 22 fluidounces) of diluted alcohol, and, having moistened the powder with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, pack it moderately in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding first the remainder of the menstruum, and afterward diluted alcohol, until the leptandra is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

It is not clear why a weaker alcoholic menstruum should be desirable for making a liquid preparation than was deemed necessary for preparing the extract of the same drug. The menstruum chosen for the latter—viz. 2 parts of alcohol to 1 part of water—was found by Alonzo Robbins to furnish a fluid extract which will keep unaltered for several years, even without the addition of glycerin. It is of a dark red-brown color and has a very bitter taste.

Dose, 30 to 60 minims (Gm. 2–4).

EXTRACTUM LOBELIÆ FLUIDUM, U. S.—FLUID EXTRACT OF LOBELIA.

Extrait liquide de lobélie enflée, Fr.; *Flüssiges Lobelieneextrakt*, G.

Preparation.—Lobelia, in No. 60 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8¾ oz. av. or 9 fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the lobelia is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This new pharmacopœial preparation is of a deep green-brown color, has the unpleasant acid taste of the drug, and if properly made and kept remains in good condition.

Medical Uses.—*Dose*, as an emetic, 10 to 20 minims (Gm. 0.60–1.30); as an expectorant, 1 to 5 minims (Gm. 0.06–0.30).

EXTRACTUM LUPULI, Br.—EXTRACT OF HOP.

Extractum humuli.—*Extrait de houblon*, Fr.; *Hopfenextrakt*, G.

Preparation.—Take of Hop 1 pound; Rectified Spirit $1\frac{1}{2}$ pints; Distilled Water 1 gallon. Macerate the hop in the spirit for 7 days, press out the tincture; filter, and distil off the spirit, leaving a soft extract. Boil the residual hop with the water for 1 hour, press out the liquor, strain, and evaporate by a water-bath to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F., until it has acquired a suitable consistence for forming pills.—*Br.*

Alcohol is required for exhausting the lupulin of hops, and would also exhaust hops if used in sufficient quantity; the subsequent use of water is a saving of alcohol. The extract of the French Codex, which is made with alcohol of 60 per cent. by volume, is preferable. The yield is about 20 per cent.

Medical Uses.—This preparation represents pretty well the virtues of hop. *Dose*, 5 grains (Gm. 0.30) or more.

EXTRACTUM LUPULINÆ FLUIDUM, U. S.—FLUID EXTRACT OF LUPULIN.

Extrait liquide de lupuline, Fr.; *Flüssiges Lupulin-Extrakt*, G.

Preparation.—Lupulin 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the lupulin with 20 Gm. (5 oz. av. or $5\frac{1}{2}$ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the lupulin and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the lupulin is exhausted. Reserve the first 70 Ccm. ($16\frac{3}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The use of alcohol is necessary to keep the volatile oil and resinous matter in solution, and the preparation fairly represents the drug. Mr. Alonzo Robbins suggests the lupulin to be packed without previously moistening it, as then the percolation proceeds evenly and without any difficulty, while the moistened powder is apt to form a tough mass difficult to percolate. The fluid extract is of a deep red-brown color and of the odor and taste of the drug.

Medical Uses.—It affords a convenient mode of administering lupulin. The *dose* is 15 or 20 minims (Gm. 1.00–1.30), which should be mixed with syrup or brandy and afterward diluted with water.

EXTRACTUM MALTI, U. S.—EXTRACT OF MALT.

Essence (Extrait) de malt, Fr.; *Malzextrakt*, G.

Preparation.—Malt, in coarse powder, not finer than No. 12, 100 parts (100 oz. av.); Water a sufficient quantity. Upon the powder, contained in a suitable vessel, pour 100 parts of water, and macerate for 6 hours. Then add 400 parts (400 oz. av. or 24 pints) of water heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceeding 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath or vacuum-apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid rapidly to the consistence of thick honey. Keep the product in well-closed vessels in a cool place.—*U. S.*

In making this extract, which is now for the first time admitted into the Pharmacopœia, it is of the utmost importance that the temperature should never exceed 65° C. (149° F.), and it is safer, for the preservation of the diastase, to keep it at or below 55° C. (131° F.) until the starch of the malt has been converted into glucose and dextrin. According to Payen and Persoz, good malt contains 2 per cent of diastase, and since 1 part of this compound is estimated to convert 2000 parts of starch, it is obvious that properly-prepared malt extract should contain nearly the entire amount of diastase which was originally present in the malt. This is only accomplished by the rapid evaporation of the infusion at a temperature which does not act injuriously upon diastase, as is directed in the pharmacopœial process. The yield is from 65 to 75 per cent.

Properties.—Extract of malt is a brown-yellow or light amber-colored, thick liquid or semi-fluid mass, having a slight peculiar odor, a sweet mucilaginous taste, and a dis-

tinctorial acid reaction to litmus-paper. It dissolves in water in all proportions, yielding a nearly transparent solution, in which alcohol produces a milky turbidity, after a short time becoming clear, with the separation of a flocculent precipitate. The aqueous solution also yields precipitates with picric acid, tannin, most alkaloidal reagents, and mercuric chloride and other metallic salts. When the extract is added to starch-paste, this is gradually liquefied, and will finally not acquire a blue color on the addition of iodine solution. On heating the extract it is decomposed, giving off the odor of burning sugar, and finally leaving a small amount of ash.

Constituents.—Good extract of malt contains about 30 per cent. of water, 60 of maltose and dextrin, 8 of nitrogenated principles, and $1\frac{1}{2}$ of ash. Maltose and dextrin are usually present in nearly equal proportion, the former somewhat predominating. A minute amount of free lactic and perhaps of other acids is likewise present.

Valuation.—(For valuable papers on the analysis of malt-extract consult W. H. Dunstan and A. F. Dimmock in *Phar. Jour. and Transactions*, March, 1879, p. 734, and J. F. C. Jungk in *Amer. Jour. Phar.*, June, 1883, p. 289.) The amount of solid matter may be determined from the specific gravity, which is not identical with that of a solution containing the same percentage of cane-sugar. Hager has constructed the annexed table, which gives the density at 17.5° C. (63.5° F.) and the amount of solids dried at 110° C. (230° F.):

Table of Specific Gravity at 17.5° C. and Percentage of Solids, Dried at 110° C., of Extract of Malt.

Solids.	Specific gravity.	Solids.	Specific gravity.	Solids.	Specific gravity.	Solids.	Specific gravity.	Solids.	Specific gravity.
1	1.0035	11	1.0448	21	1.0866	31	1.1305	41	1.1792
2	1.0072	12	1.0490	22	1.0908	32	1.1353	42	1.1844
3	1.0112	13	1.0532	23	1.0950	33	1.1401	43	1.1897
4	1.0154	14	1.0574	24	1.0991	34	1.1449	44	1.1952
5	1.0197	15	1.0616	25	1.1033	35	1.1497	45	1.2007
6	1.0238	16	1.0658	26	1.1075	36	1.1545	46	1.2062
7	1.0279	17	1.0700	27	1.1117	37	1.1594	47	1.2119
8	1.0321	18	1.0741	28	1.1159	38	1.1643	48	1.2178
9	1.0363	19	1.0782	29	1.1202	39	1.1692	49	1.2239
10	1.0406	20	1.0824	30	1.1258	40	1.1741	50	1.2303

Should the extract be too thick, it is to be dissolved in an equal weight of distilled water. According to Jungk, 5 Gm. of the extract are mixed with 20 Gm. of well-washed and dried sand, and the mixture is dried at 100° C.; the loss in weight indicates the water. The dry powder is, in a small percolator, exhausted with ether, the loss being resin of hops if present. A mixture of 2 volumes of strong alcohol and 1 volume of ether will next take up glycerin; then the maltose is dissolved by alcohol, and afterward the dextrin by boiling water. On heating the sand to redness, the albuminates are burned, and estimated by loss of weight. The diastatic strength of extract of malt is determined by forming starch into paste with about 20 parts of boiling water, and digesting it with the extract. According to Jungk, properly-prepared extract of malt should convert its own weight of starch at 16.6° C. (62° F.) in 40 minutes, or at 37.8° C. (100° F.) in 10 minutes, or at 65.5° C. (150° F.) in 3 minutes. The proteids may be estimated, according to Hager, by digesting for 30 minutes 10 Gm. of extract of malt with 100 Gm. of aqueous solution of picric acid saturated in the cold, washing the precipitate, and drying; one-half the weight is about equal to the albuminoids, of which from 3 to 3.25 per cent. should be present (Jungk).

Some commercial malt extracts are scarcely superior to glucose; others consist of a stronger or weaker beer.

Pharmaceutical Uses.—Extract of malt is serviceable in emulsifying fixed oil and as a vehicle for various medicaments.

EXTRACTUM MALTI FERRATUM (*P. G.* 1872) is made by dissolving 2 parts of pyrophosphate of iron in 3 parts of water, and incorporating the solution with 95 parts of extract of malt. Hager (1876) recommends instead the use of 3 parts of saccharated iron rubbed up with 7 of glycerin and 90 of extract of malt.

If quinine is combined with malt, the neutral tannate of quinine is best employed. Hops may be used with it in the form of fluid extract of lupulin. A combination with pepsin should be made extemporaneously, since the taste is gradually modified.

EXTRACTUM MALTI FLUIDUM, suggested by Prof. Lloyd, may be made by macerating

and percolating 4 parts of ground malt with a mixture of 1 part of alcohol and 4 parts of water until 3 parts of percolate are obtained. It is a thin yellow or brownish liquid, containing the malt-sugar and diastase, the latter being destroyed on the application of heat.

Medical Uses.—(See MALTUM.) It is a condiment and digestive whose *dose* must vary with individual cases.

EXTRACTUM MATICO FLUIDUM, U. S.—FLUID EXTRACT OF MATICO.

Extrait liquide de matico, Fr.; Flüssiges Matico-Extrakt, G.

Preparation.—Matico, in No. 40 powder, 100 Gm. (25 oz. av.); Glycerin, 10 Gm. (2½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix the glycerin with 75 Gm. (18¼ oz. av. or 22 fluidounces) of alcohol and 25 Gm. (6¼ oz. av. or 6 fluidounces) of water, and, having moistened the powder with 30 Gm. of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water made in the proportion of 3 parts (37 measures) of alcohol to 1 part (10 measures) of water, until the matico is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the same proportions as before, to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Compared with the formula of 1870, the glycerin has been reduced to one-third the former quantity, and the alcohol increased in strength. The deep brown-green fluid extract contains the virtues of the drug well preserved.

Medical Uses.—The utility of this preparation consists in the facility with which it is absorbed. It may be given in *dose* of from ½ fluidrachm to 2 fluidrachms (Gm. 2–8).

EXTRACTUM MEZEREI, U. S.—EXTRACT OF MEZEREUM.

Extrait de garou, Fr.; Seidelbast-Extrakt, G.

Preparation.—Mezereum, in No. 30 powder, 100 parts (20 oz. av.); Alcohol a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 9¾ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding alcohol, until 300 parts (60 oz. av. or about 68 fluidounces) of tincture are obtained or the mezereum is exhausted. Reserve the first 90 parts (18 oz. av. or about 20 fluidounces) of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 10 parts (2 oz. av.); mix this with the reserved portion and evaporate, at or below the before-mentioned temperature, in a porcelain capsule on a water-bath, to a pilular consistence.—*U. S.*

Mezereum containing no volatile principle, and the constituents not being injured at the temperature of boiling alcohol, there is no reason why most of the alcohol should not be recovered by distillation, as directed by other pharmacopœias. It is simply impossible to obtain this extract of a pilular consistence. The yield is from 10 to 12 per cent. This, like the following extract, is of a green color and insoluble in water.

Off. Prep.—Linimentum sinapis compositum, *U. S.*

EXTRACTUM MEZEREI ÆTHEREUM, *Br., F. Cod.*—Extrait éthéré de garou (de mézéréon). *Fr.;* Ätherisches Seidelbast-Extrakt, *G.*—The alcoholic tincture is distilled until a soft extract remains; this is agitated with ether, the ethereal solution decanted, the ether recovered by distillation, and the residue converted into a soft extract. The yield is 6 or 7 per cent. This extract retains the consistence of honey.

Medical Uses.—It is a powerful irritant, and may be added to stimulant and rubefacient liniments and ointments to increase their power. It is an ingredient of the compound liniment of mustard, *Br. P.*

EXTRACTUM MEZEREI FLUIDUM, U. S.—FLUID EXTRACT OF MEZEREUM.

Extrait liquide de mézéréon (de garou). Fr. ; Flüssiges Seidelbast-Extrakt, G.

Preparation.—Mezereum, in No. 30 powder, 100 Gm. (25 oz. av.): Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 11½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the mezereum is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

This fluid extract, which is of a green color and very acrid, is used in the preparation of Unguentum mezerei, for which purpose it is very convenient. Except in manipulation no change has been made in the formula. As in the preceding case, the alcohol may be recovered by distillation without detriment to the preparation.

Medical Uses.—Diluted, this extract may take the place of decoction of mezereum. But as an overdose of it, undiluted, may give rise to violent and even fatal effects, this mode of administration is ineligible. The *dose* is nominally from 1 to 5 or 10 minims (Gm. 0.06–0.60). Its chief use is its external application to maintain a discharge from blistered surfaces.

EXTRACTUM NUCIS VOMICÆ, U. S., Br.—EXTRACT OF NUX VOMICA.

Extractum strychni, P. G.; Extractum nucum vomicarum spirituosum (vel alcoholicum).—Extrait de noix vomique, Fr. ; Strychnossamen-Extrakt, Krähenaugen-Extrakt, G.

Preparation.—Nux Vomica, in No. 60 powder, 100 parts (20 oz. av.); Alcohol, Water, each a sufficient quantity. Mix alcohol and water in the proportion of 8 parts (50 fluidounces) of alcohol with 1 part (5½ fluidounces) of water, and, having moistened the powder with 100 parts (20 oz. av. or 23 fluidounces) of the mixture, let it macerate in a closed vessel in a warm place for 48 hours. Then pack it in a cylindrical percolator, and gradually pour menstruum upon it until the tincture passes but slightly imbued with bitterness. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence.—U. S.

Take of nux vomica 1 pound; rectified spirit a sufficiency. Apply steam to the nux vomica until it is thoroughly softened, then dry rapidly and reduce to fine powder. Exhaust the powder by boiling it with successive portions of the spirit until the latter comes off nearly free from bitterness. Strain, distil off the spirit, and evaporate by a water-bath to the consistence of a soft extract.—Br.

The French Codex directs maceration with alcohol of 80 per cent. by volume sp. gr. .864; the German Pharmacopœia, digestion with alcohol sp. grav. .894. The menstruum of the U. S. P. has the density .846, that of the Br. P., .838.

Nux vomica is exceeding difficult to powder; the object is best accomplished on a small scale by somewhat crushing the seeds and drying them well by heat, or by heating them with a little water until they become soft enough to be bruised, while still warm, into a pulpy mass, with which a little alcohol is incorporated, when they should be thoroughly dried and powdered for displacement. Where steam is available for the softening of the seeds we would recommend that they be crushed or bruised while hot. In this way the rapid drying will be facilitated. The fatty matter contained in the seeds is taken up by the alcohol, and retains a portion of the alkaloids in solution; it is evidently not intended by either pharmacopœia that it should be removed. Its incorporation with the extract is hastened if the tincture is evaporated to a thin syrupy consistence, when hot water should be added with constant stirring, and the mixture then evaporated with continual agitation. The extract will be somewhat greasy; to avoid this the oil may be removed, but since it contains notable quantities of the alkaloids, it should be repeatedly agitated with fresh portions of alcohol of about .880 or .890 spec. grav. until it has nearly lost its bitter taste, and the alcoholic liquid should be added to and evaporated with the remaining extract. If the pharmacopœias would direct alcohol of the strength

indicated, all of the alkaloids, with but little of the fat, would be dissolved, and the extract could be evaporated to dryness and powdered. The official extract is of a yellowish-brown color and of an intensely bitter taste. The yield is variable; with alcohol sp. gr. .835 we have obtained from 8 to 11.3 per cent. of the weight of the seeds; with weaker alcohol the yield is increased. It contains about 6 per cent. of strychnine, but this percentage must necessarily vary.

EXTRACTUM STRYCHNI (NUCIS VOMICÆ) AQUOSUM is prepared from coarsely-powdered nux vomica by digesting it with hot water and evaporating the infusion to dryness. The yield is about 16 per cent., and the extract contains about 2 or 3 per cent. of strychnine.

Medical Uses.—It is chiefly used as an ingredient of pills intended to overcome habitual atonic constipation. The primary *dose* is about $\frac{1}{2}$ grain (Gm. 0.03); it may gradually be increased to 2 or 3 grains (Gm. 0.10–0.20) when the specific action of the drug is sought.

EXTRACTUM NUCIS VOMICÆ FLUIDUM, U. S.—FLUID EXTRACT OF NUX VOMICA.

Extrait liquide de noix vomique, Fr.; Flüssiges Strychnosamen-Extrakt, G.

Preparation.—Nux Vomica, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 8 parts (40 oz. av. or 47 fluidounces) of alcohol with 1 part (5 oz. av. or 4 $\frac{1}{4}$ fluidounces) of water, and, having moistened the powder with 100 Ccm. (24 fluidounces) of the mixture, let it macerate in a closed vessel in a warm place for 48 hours. Then pack it in a cylindrical percolator, and gradually pour menstruum upon it until the tincture passes but slightly imbued with bitterness. Reserve the first 90 Ccm. (21 $\frac{1}{2}$ fluidounces) of the percolate. By means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

(For remarks on the manipulation we refer to the preceding article.) The menstruum being of precisely the same strength as that directed for the abstract, extract, and tincture, this fluid extract would seem to be adapted for the extemporaneous preparation of these.

Medical Uses.—On account of its intense bitterness, this is an ineligible preparation. It should be largely diluted with water. *Dose*, from 1 minim to 5 or more, cautiously increased.

EXTRACTUM OPII, U. S., Br., P. G.—EXTRACT OF OPIUM.

Extractum thebaicum.—Extrait d'opium, Extrait thebaïque, Fr.; Opiumextrakt, G.

Preparation.—Opium, 100 parts (1 lb. av.); Water 750 parts (7 $\frac{1}{2}$ lbs. av. or 7 pints); Glycerin a sufficient quantity. Cut the opium into small pieces, let it macerate for 24 hours in 150 parts (1 $\frac{1}{2}$ lbs. av. or 23 fluidounces) of the water, and reduce it to a soft mass by trituration. Express the liquid from it, and treat the residue again in the same manner with 150 parts (1 $\frac{1}{2}$ lbs. av. or 23 fluidounces) of the water. Repeat the maceration and expression three times more, using a fresh portion of the water each time. Having mixed the liquids, filter the mixture, and evaporate by means of a water-bath to a pilular consistence. Lastly, weigh the extract and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—U. S.

The pharmacopœias agree in ordering cold water for the extraction of crude opium; only the German Pharmacopœia directs the use of powdered opium, and the U. S. P. alone orders common water, the other authorities directing distilled water. The manipulation does not differ materially except in the number of macerations and the proportion of water used. For 1 part of opium two macerations are directed with 8 and 4 parts, *F. Cod.* (with 5 and 2 $\frac{1}{2}$ parts, *P. G.*), of water; three macerations each with 2 $\frac{1}{2}$ parts of water, *Br.*, and five macerations each with 1 $\frac{1}{2}$ parts of water, *U. S.* The latter process could be improved by using for the first maceration 3 parts of water, and shortening the time for the subsequent macerations to 12 hours each. The macerations should be effected at a low temperature, say about 60° F. At a higher temperature a larger amount of extract is obtained, more largely contaminated with narcotine and other principles, and of an inferior quality. The expressed liquids may be set aside for some time to settle, and then at once passed through a well-moistened filter without waiting until

the maceration is completed with the whole amount of water. A flannel strainer is well adapted for the purpose if it is thoroughly moistened with water and the filtrate returned upon the strainer as long as it passes turbid. The evaporation is completed in the water-bath, and might be continued until a dry extract remains, which may be rubbed into a reddish-brown powder, as directed by the P. G.; the other pharmacopœias require it to be of the proper consistence of an extract, to preserve which the addition of glycerin will be useful. The yield is 55 to 60 per cent. of the *dry* opium employed, and the extract should contain not less than 20 per cent. of morphine, to correspond with opium of 12 per cent. morphine strength.

Denarcotized extract of opium is still occasionally employed. It may be obtained by agitating the concentrated infusion with 2 portions of ether, each time allowing the mixture to settle, and decanting the ether, which dissolves the narcotine, but not the morphine; the aqueous liquid is then evaporated as before. This extract is probably in no way superior to the official preparation.

Pharmaceutical Uses.—**UNGUENTUM OPIATUM.** Unguentum opii, opium ointment, is made by triturating 1 part of extract of opium with 1 part of water and adding 18 parts of simple ointment, *P. G.* 1872.

Off. Prep.—Emplast. opii, *U. S.*; Extract. opii liquid., *Br.*; Trochisci glycyrrh. et opii, *U. S.*; Troch. opii, Vinum opii, *Br.*

Medical Uses.—This preparation is essentially opium purified from its inert constituents. Its average *dose* is about $\frac{1}{2}$ grain (Gm. 0.03).

EXTRACTUM OPII LIQUIDUM, *Br.*—LIQUID EXTRACT OF OPIUM.

Extrait liquide d'opium, Fr.; *Flüssiges Opiumextrakt*, G.

Preparation.—Extract of Opium 1 ounce; Distilled Water 16 fluidounces; Rectified Spirit 4 fluidounces. Macerate the extract of opium in the water for an hour, stirring frequently; then add the spirit and filter. The product should measure 1 pint (Imperial). It contains 22 grains of extract of opium (nearly) in 1 fluidounce.—*Br.*

This is somewhat stronger in opium than the tincture of opium, *Br.*, and scarcely deserves to be classed with the fluid extracts; it is analogous to the Tinctura opii deodorata, *U. S.*

Medical Uses.—Essentially a solution of the watery extract of opium, this preparation is probably less apt to nauseate and constipate than laudanum. *Dose*, from 10 to 30 minims (Gm. 0.60–2.00).

EXTRACTUM PAPAVERIS, *Br.*—EXTRACT OF POPPIES.

Extrait de pavot (capsules), Fr.; *Mohnextrakt*, G.

Preparation.—Poppy-Capsules, dried, freed from the seeds, and coarsely powdered. 1 pound; Rectified Spirit 2 ounces; Boiling Distilled Water a sufficiency. Mix the poppy-capsules with two pints of the water and infuse for 24 hours, stirring them frequently; then pack them in a percolator, and, adding more of the water, allow the liquor slowly to pass until about a gallon has been collected or the poppies are exhausted. Evaporate the liquor by a water-bath until it is reduced to a pint, and when cold add the spirit. Let the mixture stand for 24 hours, then separate the clear liquor by filtration, and evaporate this by a water-bath until the extract has acquired a suitable consistence for forming pills.—*Br.*

Warm water extracts, with the medicinal principles, also the mucilaginous matters, which are but imperfectly precipitated by the small quantity of alcohol added. The yield is about 30 per cent. The French Codex directs extraction with 60 per cent. alcohol, which yields about 15 per cent. of extract.

Medical Uses.—This extract appears to be unnecessary. It has no virtues that are not more decided in the various preparations of opium. *Dose*, from 2 to 5 grains (Gm. 0.10–0.30).

EXTRACTUM PAREIRÆ, *Br.*—EXTRACT OF PAREIRA.

Extrait de pareira brava, Fr.; *Pareira-Extrakt*, G.

Preparation.—Pareira-Root, in coarse powder, 1 pound; Boiling Distilled Water 1 gallon or a sufficiency. Digest the pareira with a pint of the water for 24 hours, then pack in a percolator, and, adding more of the water, allow the liquor slowly to pass until

a gallon has been collected or the pareira is exhausted. Evaporate the liquor by a water-bath until the extract has acquired a suitable consistence for forming pills.—*Br.*

The use of boiling water, followed by prolonged digestion, must result in the solution of the starch, which is but imperfectly removed by the subsequent percolation. A diluted alcohol would seem to be a very appropriate menstruum for exhausting pareira.

Medical Uses.—The solid form of a medicine intended to act upon the mucous membrane of the urinary passages cannot be an eligible one. The fluid extract and the decoction are greatly preferable. *Dose*, from 10 to 20 grains (Gm. 0.60–1.20).

EXTRACTUM PAREIRÆ FLUIDUM, U. S.—FLUID EXTRACT OF PAREIRA.

Extractum pareiræ liquidum, Br.—*Liquid extract of pareira*, E.; *Extrait liquide de pareira brava*, Fr.; *Flüssiges Pareira-Extrakt*, G.

Preparation.—Pareira, in No. 40 powder, 100 Gm. (25 oz. av.); Glycerin 20 Gm. (5 oz. av.); Diluted Alcohol a sufficient quantity, to make 100 Cem. (24 fluidounces). Mix the glycerin with 80 Gm. (20 oz. av. or 20½ fluidounces) of diluted alcohol, and, having moistened the powder with 40 Gm. (10 oz. av. or 10½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the pareira is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate. By means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

Take of pareira-root, in coarse powder, 1 pound; boiling distilled water 1 gallon or a sufficiency; rectified spirit 3 fluidounces. Digest the pareira with a pint of the water for 24 hours; then pack in a percolator, and, adding more of the water, allow the liquor slowly to pass until a gallon has been collected or the pareira is exhausted. Evaporate the liquor by a water-bath to 13 fluidounces, and when it is cold add the spirit and filter through paper.—*Br.*

The latter formula gives a concentrated infusion, preserved by the addition of a little alcohol. The root is more readily and advantageously extracted by an alcoholic menstruum; that directed by the first formula differs but little from the one ordered in 1870, except in the reduction of the glycerin to two-thirds of the former quantity, but would be improved by using in place of diluted alcohol a mixture of 2, or, as suggested by Mr. Robbins, of 3, parts of alcohol and 1 part of water. The fluid extract is of a brown color, and possesses the peculiar bitter taste of the root in a marked degree.

Medical Uses.—This preparation probably contains all the medicinal qualities of pareira brava. It may be given in teaspoonful *doses* (Gm. 4) three times a day, largely diluted.

EXTRACTUM PHYSOSTIGMATIS, U. S.. *Br.*—EXTRACT OF PHY- STIGMA.

Extractum fabæ Calabariæ.—*Extrait alcoolique de fève de Calabar*, Fr.; *Kalabar-bohnenextrakt*, *Physostigmaextrakt*, G.

Preparation.—Physostigma, in No. 40 powder, 100 parts (20 oz. av.); Alcohol a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 9½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 300 parts (60 oz. av. or about 68 fluidounces) of tincture are obtained or the physostigma is exhausted. Reserve the first 90 parts (18 oz. av. or 20 fluidounces) of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 10 parts (2 oz. av.); mix this with the reserved portion, and evaporate in a porcelain capsule on a water-bath to a pilular consistence.—*U. S.*

The British Pharmacopœia directs maceration and percolation with alcohol spec. grav. .838; the French Codex orders digestion for 2 hours, followed by percolation with hot alcohol spec. grav. .864; the former German Pharmacopœia employed alcohol spec. gr. .893, and exhausted by maceration. Strong alcohol yields only $2\frac{1}{2}$ or 3 per cent. of extract, which, owing to the resinous and oily constituents, is obtainable of a homogeneous condition only by constant stirring during the latter part of the process. By the use of weaker alcohol a more uniform and less oily extract is obtained, and the yield is increased to 10 or 12 per cent. It is evident from this that the strict adherence to the menstruum directed by the pharmacopœias is of primary importance. The extract is of a greenish-brown color. Kennedy (1875) suggested the addition of glycerin to keep it soft and to render it more convenient for dispensing.

Medical Uses.—The extract represents all the active constituents of Calabar bean. Its average dose may be stated at $\frac{1}{10}$ grain (Gm. 0.006). Hiller used, to overcome constipation with flatulent distension of the bowel, the following: Ext. Calabar bean Gm. 0.10; Glycerin 30 Gm.—M. S. 10 drops, equal to about $\frac{1}{56}$ grain, three or four times a day.

EXTRACTUM PILOCARPI FLUIDUM, U. S.—FLUID EXTRACT OF PILOCARPUS.

Fluid extract of jaborandi, E.; *Extrait liquide de jaborandi*, Fr.; *Flüssiges Jaborandi-extrakt*, G.

Preparation.—Pilocarpus, in No. 40 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 35 Gm. ($8\frac{3}{4}$ oz. av. or 9 fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the pilocarpus is exhausted. Reserve the first 85 Cem. ($20\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

This is essentially the process recommended by Dr. F. V. Greene (1877), who also called attention to the difficulty of packing powdered pilocarpus-leaves properly for percolation, owing to the strong fibres of the veins and the tough epidermal tissue; for which reason he suggested placing a rather thick layer of sand upon the powder. The fluid extract is of a greenish-red-brown color. A somewhat more aqueous menstruum has been suggested by Mr. Alonzo Robbins as preserving the properties equally well.

Medical Uses.—This preparation is far inferior in promptness and efficiency of action to pilocarpin administered hypodermically, but is preferable to the other liquid preparations of jaborandi. *Dose*, 10 to 15 minims (Gm. 0.60–1), gradually increased, at short intervals, until its specific operation is manifested.

EXTRACTUM PODOPHYLLI, U. S.—EXTRACT OF PODOPHYLLUM.

Extract of May-apple or of mandrake, E.; *Extrait de podophylle*, Fr.; *Podophyllum-extrakt*, G.

Preparation.—Podophyllum, in No. 60 powder, 100 parts (20 oz. av.); Alcohol, Water, each a sufficient quantity. Mix alcohol and water in the proportion of 3 parts (or 22 fluidounces) of alcohol with 1 part (or 6 fluidounces) of water, and, having moistened the powder with 30 parts (6 oz. av. or $6\frac{1}{2}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until 500 parts (100 oz. av.) of tincture have passed. By means of a water-bath distil off the alcohol from the tincture, and evaporate the residue to a pilular consistence.—U. S.

The menstruum is sufficiently alcoholic for the extraction of the medicinally valuable principles, and for not dissolving those least desirable. The extract is of a deep-brown color, and is not disposed to mould, as was the case with the former extracts, which were prepared with alcohol followed by diluted alcohol or water.

Medical Uses.—The operation of this medicine closely resembles that of extract of

jalap: it may be used for the same purpose in the dose of from 5 to 20 grains (Gm. 0.30–1.20).

EXTRACTUM PODOPHYLLI FLUIDUM.—FLUID EXTRACT OF PODOPHYLLUM.

Fluid extract of May-apple or of mandrake, E.; Extrait liquide de podophylle, Fr.; Flüssiges Podophyllumextrakt, G.

Preparation.—Podophyllum, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix 3 parts (or 70½ fluidounces) of alcohol with 1 part (or 19½ fluidounces) of water, and, having moistened the powder with 30 Gm. (6 oz. av. or 6½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the podophyllum is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder; dissolve the residue in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This fluid extract is of a dark brown-red color. Being prepared with the same menstruum, it may be used for the extemporaneous preparation of the preceding extract.

Medical Uses.—It is inferior to the solid extract for most of the purposes for which podophyllum is used. *Dose*, 10 to 20 minims (Gm. 0.60–1.20).

EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM.—FLUID EXTRACT OF WILD CHERRY.

Extrait liquide d'écorce de cerisier de Virginie, Fr.; Flüssiges Wildkirschenrinden-Extrakt, G.

Preparation.—Wild Cherry, in No. 20 powder, 100 Gm. (25 oz. av.); Diluted Alcohol, Glycerin, Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix 2 parts (8½ oz. av. or 8 fluidounces) of water with 1 part (4½ oz. av.) of glycerin, and, having moistened the powder with 50 Gm. (12½ oz. av.) of the mixture, pack it loosely in a cylindrical percolator, cover the latter well, and set it aside for 48 hours. Then pack the damp powder firmly in the percolator, and pour on enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the wild cherry is exhausted. Reserve the first 80 Cem. (19½ fluidounces) of the percolate and set it aside; collect the next 120 Cem. (30 oz. av. or 30 fluidounces) separately, and evaporate to a thin syrup. By means of a water-bath distil off the alcohol from the remainder of the percolate and evaporate the residue to a thin syrup. Unite the two syrupy liquids and evaporate them on a water-bath to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This is one of those troublesome fluid extracts the formula of which has been changed since its introduction in each subsequent edition of the Pharmacopœia. The one suggested by Prof. Procter in 1859, in which the bark was exhausted by alcohol, and after the evaporation of the menstruum the decomposition of amygdalin was effected by emulsion of almonds, was an efficient and elegant preparation, but objected to on account of troublesome manipulation. The present formula is based upon that of 1870, the main difference being a reduction of glycerin and the final displacement with diluted alcohol in the place of alcohol. While the present menstruum dissolves little or none of the resinous matter, the fluid extract, though it yields clear mixtures with aqueous liquids, is open to the objection that was urged against that of 1870—of depositing considerable precipitate. A preparation which is nearly free from this objection is made by the following process, elaborated by Mr. Alonzo Robbins in 1879 and published in 1883: 100 parts (25 oz. av.) of wild cherry, in No. 40 powder, are moistened with 50 parts (12½ oz. av. or 12 fluidounces) of water and set aside for 24 hours: 20 parts (5 oz.

av.) of sugar are then mixed with the damp powder, and the whole packed in a percolator and saturated with a mixture of 1 part (1 measure) of alcohol and 6 parts (5 measures) of water, and allowed to macerate for 48 hours; then the percolation is allowed to proceed, adding the same mixture of alcohol and water, until the wild cherry is exhausted. The first 80 parts (19½ fluidounces) of the percolate are reserved; 10 parts (2½ oz. av.) of glycerin are added to the remainder, which is then evaporated to a soft extract; this is dissolved in the reserved portion, and a sufficient quantity of the menstrum added to make 100 parts (24 fluidounces).

The fluid extract is of a deep brownish-red color, and when recently made has the bitter-almond odor in a marked degree, and possesses also the astringent and pleasantly bitter taste of the bark; the odor diminishes in the course of time, and finally disappears.

Medical Uses.—If well prepared, this extract represents more fully and in a more convenient form than any other preparation the virtues of wild-cherry-bark. It is an excellent adjuvant to cough mixtures in chronic *pulmonary* affections, and a palliative of *nervous* disorder of the heart's action. The *dose* is from 30 minims to a fluidrachm (Gm. 2-4), and should be gradually increased.

EXTRACTUM QUASSIÆ, U. S., Br., P. G.—EXTRACT OF QUASSIA.

Extrait de quassie (bois amer), Fr.; Quassienextrakt, G.

Preparation.—Quassia, in No. 20 powder, 100 parts (20 oz. av.); Glycerin. Water, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 7½ fluidounces) of water, pack it firmly in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with bitterness. Reduce the liquid to three-fourths of its weight by boiling and strain; then by means of a water-bath evaporate to a pilular consistence. Lastly, weigh the extract, and thoroughly incorporate with it, while still warm, 5 per cent. of glycerin.—*U. S.*

The British, French, and German Pharmacopœias unite in ordering distilled water; the latter alone orders hot digestion. With cold water the yield varies between 2½ and 5 per cent. J. S. Whall (1874) observed that 1 part of quassia is practically exhausted by obtaining from it 4 parts of percolate, and will yield rather less than 3½ per cent. of extract if water, or a little more if diluted alcohol, is used; the latter is considered preferable. The yield is increased to about 6 or 7 per cent. if boiling water is used, but the extract has a jelly-like appearance, probably from pectin compounds, and after some time contains a considerable quantity of crystals. The concentrated infusion should be filtered before final evaporation, as directed by the British Pharmacopœia.

Medical Uses.—The intense bitterness of this preparation denotes its possession of the virtues of quassia in a concentrated state. Like all other bitter extracts, it should not be given in that form unless in a very small *dose*, such as 1 or 2 grains (Gm. 0.06-0.12). It is usually associated with tonics of another order—*e. g.* quinine, iron, etc.

EXTRACTUM QUASSIÆ FLUIDUM.—FLUID EXTRACT OF QUASSIA.

Extrait liquide de quassie, Fr.; Flüssiges Quassienextrakt, G.

Preparation.—Quassia, in No. 60 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 40 Gm. (10 oz. av. or 10½ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the quassia is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Diluted alcohol is a good menstrum for permanently dissolving the bitter principle of quassia. The fluid extract has a brown-yellow color and a persistently bitter taste.

Medical Uses.—The intense bitterness of this preparation renders it ineligible as an internal medicine unless it is largely diluted. It may be used as an addition to various bitter tonic mixtures. *Dose*, 5 to 20 minims (Gm. 0.30-1.30).

EXTRACTUM RHEI, U. S., Br., P. G.—EXTRACT OF RHUBARB.*Extractum rhei alcoholicum.*—*Extrait de rhubarbe*, Fr.; *Rhabarberextrakt*, G.

Preparation.—Rhubarb, in No. 30 powder, 100 parts (20 oz. av.); Alcohol, Water, each a sufficient quantity. Mix alcohol and water in the proportion of 3 parts (or 37 fluidounces) of alcohol and 1 part (or 10 fluidounces) of water, and, having moistened the powder with 40 parts (8 oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a conical percolator; then gradually pour the menstruum upon it until the tincture passes nearly tasteless. Reserve the first 100 parts (20 oz. av. or about 20 fluidounces) of the percolate, and set it aside in a warm place until it is reduced by spontaneous evaporation to 50 parts (10 oz. av.) Evaporate the remainder of the percolate in a porcelain vessel by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to the consistence of syrup; mix this with the reserved portion, and continue the evaporation until the mixture is reduced to a pilular consistence.—*U. S.*

The other pharmacopœias prepare this extract by maceration, and employ a menstruum composed of 2 parts of alcohol sp. gr. .832 and 3 parts of water, *P. G.*; 1 measure of alcohol sp. gr. .838 and 10 measures of water, *Br.*; cold distilled water, *F. Cod.* Each of these liquids gives an efficient extract, the yield of which necessarily varies with the quality of the root, it being from 35 to 40 per cent. when made with cold water, and from 40 to 50 per cent. if prepared with an alcoholic liquid. The extract is yellowish-brown, bitter, has the odor of rhubarb, and yields with water a turbid solution.

EXTRACTUM RHEI COMPOSITUM, P. G. Extract of rhubarb 30 parts, extract of aloes 10 parts, resin of jalap 5 parts, and soap 20 parts; triturate together, moisten with diluted alcohol, mix well, and dry. It is of a blackish-brown color, and is also known as *Extractum catholicum s. panchymagogum*.

Medical Uses.—Owing to the difficulty of obtaining this preparation of proper quality, it is scarcely to be preferred to good rhubarb-root. Its *dose*, as a purgative, is from 10 to 15 grains (Gm. 0.60–1).

EXTRACTUM RHEI FLUIDUM, U. S.—FLUID EXTRACT OF RHUBARB.*Extrait liquide de rhubarbe*, Fr.; *Flüssiges Rhabarber-Extrakt*, G.

Preparation.—Rhubarb, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts (60 oz. av. or 70½ fluidounces) of alcohol with 1 part (20 oz. av. or 19½ fluidounces) of water, and, having moistened the powder with 40 Gm. (10 oz. av. or 11 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the rhubarb is exhausted. Reserve the first 75 Ccm. (18 fluidounces) of the percolate, and evaporate the remainder at a temperature not exceeding 70° C. (158° F.) to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This fluid extract has undergone considerable modifications. The root, exhausted by an alcoholic menstruum, and the liquid, after the evaporation of the alcohol, preserved by sugar, resulted in a fluid extract which was very thick and deposited considerably. A fluid extract prepared with cold water and preserved by sugar, as recommended by Geo. Bille (1872), is free from the last-named objection, but, it was claimed, though fairly active, not to contain *all* the purgative principles of rhubarb. The use of glycerin with an alcoholic menstruum proved a failure with the fluid extract, as it did with the tincture, the liquids, although clear for a time, precipitating more copiously afterward. The present menstruum yields a fluid extract which precipitates very slightly, but becomes thick and loses its uniformity. But by using a menstruum composed of 4 parts (or nearly 5 measures) of alcohol and 1 part (or 1 measure) of water, Alonzo Robbins (*Am. Jour. Phar.*, 1883, p. 184) obtained a preparation which for nearly four years retained its fluidity and deposited only a very slight precipitate. None of these different fluid extracts will yield clear mixtures with aqueous liquids unless an alkali be added. Fluid extract of rhubarb is of a blackish red-brown color, and has the odor and taste of the drug.

Off. Prep.—*Mistura rhei et sodæ*, *U. S.*

Medical Uses.—This preparation is not often used as a purgative, but its *dose* may be stated at from 10 to 30 minims (Gm. 0.60–2.00).

EXTRACTUM RHOS GLABRÆ FLUIDUM, U. S.—FLUID EXTRACT OF RHUS GLABRA.

Fluid extract of sumach-berries, E.; Extrait liquide de fruit de sumac, Fr.; Flüssiges Sumachbeerenextrakt, G.

Preparation.—Rhus Glabra, in No. 40 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. (2½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 90 Gm. (22½ oz. av. or 23½ fluidounces) of diluted alcohol, and, having moistened the powder with 35 Gm. (8¾ oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the rhus glabra is exhausted. Reserve the first 80 Cem. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

As originally suggested by Prof. Remington (1874), this fluid extract contained about 25 per cent. of glycerin and a slightly weaker alcohol than the above, and kept well for a long time. Mr. A. Robbins suggests a still weaker alcohol, by using 1 part of alcohol to 2 parts of water (or 25 to 41 measures), 80 parts of which menstruum are to be mixed with 20 parts of glycerin. The fluid extract is of a deep-red color, and has a pleasant acidulous and astringent taste.

Medical Uses.—The fluid extract may sometimes be more convenient than the infusion of sumach-berries treated of elsewhere. (See RHUS GLABRUM.) Diluted with water, it forms an excellent detergent and stimulating gargle and mouth-wash.

EXTRACTUM ROSÆ FLUIDUM, U. S.—FLUID EXTRACT OF ROSE.

Fluid extract of red rose, E.; Extrait liquide de rose rouge, Fr.; Flüssiges Essigrosenextrakt, G.

Preparation.—Red Rose, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. (2½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 90 Gm. (22½ oz. av. or 23½ fluidounces) of diluted alcohol, and, having moistened the powder with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, pack it firmly in a cylindrical glass percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the red rose is exhausted. Reserve the first 75 Cem. (18 fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

This newly-recognized fluid extract is of a deep-red color, of an agreeable odor of rose, and of a pleasant mildly-astringent taste.

Off. Prep.—Syrupus rosæ, U. S.

Medical Uses.—An agreeable ingredient of gargles and mouth-washes. It may take the place of rose-leaves in the compound infusion of rose; it masks the taste of solutions of Epsom and Glauber salts, and imparts a pleasing color to many magistral mixtures.

EXTRACTUM RUBI FLUIDUM, U. S.—FLUID EXTRACT OF RUBUS.

Fluid extract of blackberry-bark, E.; Extrait liquide d'écorce de ronce, Fr.; Flüssiges Brombeerrinden-Extrakt, G.

Preparation.—Rubus, in No. 60 powder, 100 Gm. (25 oz. av.); Glycerin 20 Gm. (5 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 45 Gm. (11½ oz. av. or 13½ fluidounces) of alcohol and 35 Gm. (8¾ oz. av. or 8½ fluidounces) of water, and, having moistened the powder with 35 Gm. (8¾ oz. av. or 9 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having

closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water made in the proportion of 9 parts (or 36 measures) of alcohol to 7 parts (or 23 measures) of water until the rubus is exhausted. Reserve the first 70 Ccm. (16½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the last-named proportions, to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The formula of 1870, which yielded a fairly permanent preparation, contained 50 per cent. more of glycerin, but was somewhat weaker in alcohol. A nearly permanent fluid extract, giving in three years only a very slight deposit, was obtained by Mr. A. Robbins with a mixture of 2 parts (or 22 measures) of alcohol and 1 part (or 9 measures) of water, using 10 parts of glycerin with the first 90 parts of the mixture. The deep-brown liquid has a decidedly astringent taste.

Off. Prep.—Syrupus rubi, *U. S.*

Medical Uses.—It is a good astringent, and well suited for the treatment of mild cases of *diarrhœa* in children after a sufficient evacuation of the bowels. The *dose* is from ½ fluidrachm to 2 fluidrachms (Gm. 2–8). It may, like other vegetable astringents, be added to the chalk mixture.

EXTRACTUM RUMICIS FLUIDUM, *U. S.*—FLUID EXTRACT OF RUMEX.

Fluid extract of yellow dock, E.; Extrait liquide de patience frisée, Fr.; Flüssiges Grindwurzextrakt, G.

Preparation.—Rumex, in No. 40 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 35 Gm. (8½ oz. av. or 9 fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the rumex is exhausted. Reserve the first 80 Ccm. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

This is a newly-introduced fluid extract, and has a deep red-brown color and the bitter and astringent taste of the root, which is thoroughly exhausted by the menstruum.

Dose, about a fluidrachm (Gm. 4).

EXTRACTUM SABINÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SAVINE.

Extrait liquide de sabine, Fr.; Flüssiges Sadebaum-Extrakt, G.

Preparation.—Savine, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 25 Gm. (6½ oz. av. or 7½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the savine is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The process does not differ from that of 1870, except in manipulation. The brown-green liquid contains the volatile oil, resin, and tannin of the drug, and is not only well adapted for making the official Ceratum sabinæ (*U. S.*), but it offers likewise a convenient way for administering savine.

EXTRACTUM SABINÆ is made with 60 per cent. alcohol (*F. P.*) or with a mixture of 2 parts of alcohol and 1 part of water (*P. G.*), the tincture being evaporated to the proper consistence; it has a greenish-brown color. The yield is 19 or 20 per cent.

Medical Uses.—The fluid extract appears to contain all the virtues of savine. *Dose*, from 5 to 15 minims (Gm. 0.30–1.00).

EXTRACTUM SANGUINARIÆ FLUIDUM, U. S.—FLUID EXTRACT OF SANGUINARIA.

Fluid extract of blood-root, E.; Extrait liquide de sanguinaire, Fr.; Flüssiges Blutwurz-extrakt, G.

Preparation.—Sanguinaria, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 30 Gm. (7½ oz. av. or 8¾ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the sanguinaria is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This new fluid extract, which is of a dark-red color, will probably require considerable experimentation before it is obtained in a permanent form. Liquid preparations of sanguinaria deposit a brownish-red precipitate, which was shown by F. L. Slocum (1881) to contain notable quantities of sanguinarine. Whether the precipitate occurring in the strongly alcoholic fluid extract consists only of inert coloring matter, or likewise contains sanguinarine, requires investigation. Probably the addition of a little tartaric or other vegetable acid may prevent the loss of alkaloid.

Medical Uses.—*Dose*, as an emetic, from 10 to 60 minims (Gm. 0.60–4); as a nauseant, from 3 to 5 minims (Gm. 0.20–0.30). In this concentrated form sanguinaria should be cautiously used.

EXTRACTUM SARSAPARILLÆ COMPOSITUM FLUIDUM, U. S.—COMPOUND FLUID EXTRACT OF SARSAPARILLA.

Extrait liquide de salsepareille composé, Fr.; Zusammengesetztes flüssiges Sarsaparilla-Extrakt, G.

Preparation.—Sarsaparilla, in No. 30 powder, 75 Gm. (18¾ oz. av.); Glycyrrhiza, in No. 30 powder, 12 Gm. (3 oz. av.); Sassafras-Bark, in No. 30 powder, 10 Gm. (2½ oz. av.); Mezereum, in No. 30 powder, 3 Gm. (¾ oz. av.); Glycerin 10 Gm. (2½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix the glycerin with 30 Gm. (7½ oz. av. or 8¾ fluidounces) of alcohol and 60 Gm. (15 oz. av. or 14¾ fluidounces) of water, and, having moistened the mixed powders with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of 1 part (or 14 measures) of alcohol to 2 parts (or 23 measures) of water, until the powder is exhausted. Reserve the first 80 Cem. (19½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the last-named proportions, to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

This formula differs from that of 1870 chiefly in the reduction of the glycerin and of the alcoholic strength of the menstruum. The preparation is fairly permanent. The frequent use which is made of the above combination of drugs probably renders such a fluid extract desirable, though it seems to be unnecessary, since the introduction of concentrated preparations of liquorice-root and mezereum affords the opportunity of giving these and sarsaparilla in any proportion that may be desired.

Medical Uses.—The only active ingredient in this preparation besides the sarsaparilla is mezereum. It would appear to be a less eligible medicine than the compound decoction of sarsaparilla, which contains also guaiacum, and whose efficiency is established. *Dose*, from 30 minims to a fluidrachm (Gm. 2–4).

EXTRACTUM SARSAPARILLÆ FLUIDUM, U. S.—FLUID EXTRACT OF SARSAPARILLA.

Extractum sarsæ liquidum, Br.; *Liquid extract of sarsaparilla*, E.—*Extrait liquide de sarsapareille*, Fr.; *Flüssiges Sarsaparilla-Extrakt*, G.

Preparation.—Sarsaparilla, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin, 10 Gm. (2½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Cem (24 fluidounces). Mix the glycerin with 30 Gm. (7½ oz. av. or 8¼ fluidounces) of alcohol and 60 Gm. (15 oz. av. or 14⅔ fluidounces) of water, and, having moistened the powder with 40 Gm. (10 oz. av. or 10 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum and afterward a mixture of alcohol and water made in the proportion of 1 part (or 14 measures) of alcohol to 2 parts (or 23 measures) of water, until the sarsaparilla is exhausted. Reserve the first 80 Cem (19¼ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the last-named proportions, to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

Take of Jamaica sarsaparilla, cut transversely, 1 pound; distilled water, at 160° F., 14 pints; rectified spirit 1 fluidounce. Digest the sarsaparilla in one-half of the water for 6 hours, and decant the liquor. Digest the residue in the remainder of the water for the same time, express and filter the liquors, and evaporate them by a water-bath to seven fluidounces or until the specific gravity of the liquid is 1.13. When cold, add the spirit. The specific gravity should be about 1.095.—*Br.*

Of the two preparations, the latter is apparently double the strength of the former; but the long evaporation requisite for reducing nearly 280 to 7 fluidounces is of questionable benefit, even if the root had been completely exhausted by the warm water. The first process appears to be well adapted for exhausting the root and preserving the fluid extract, which contains about one-third its measure of alcohol; an increase of the glycerin would probably improve it.

Medical Uses.—It probably contains whatever active elements belong to sarsaparilla, and serves as a basis or as a vehicle for other medicines. *Dose*, from 30 minims to a fluidrachm (Gm. 2-4).

EXTRACTUM SCILLÆ FLUIDUM, U. S.—FLUID EXTRACT OF SQUILL.

Extrait liquide de scille, Fr.; *Flüssiges Meerzwiebel-Extrakt*, G.

Preparation.—Squill, in No. 20 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces). Moisten the powder with 20 Gm. (5 oz. av. or 5⅞ fluidounces) of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the squill is exhausted. Reserve the first 75 Cem. (18 fluidounces) of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—*U. S.*

Squill yields with cold water from 55 to 65 per cent., and with diluted alcohol from 35 to 45 or 50 per cent., of extract. Alcohol which does not dissolve the gummy matter yields much less, but appears to be a solvent for all the medicinally-valuable principles. It is preferable for percolation to a more aqueous menstruum, which would cause the powder to swell. The fluid extract is of a dark brown-red color, and has the bitter and acrid taste of the drug.

EXTRACTUM SCILLÆ, *F. Cod.*, *P. G.*, is made with alcohol sp. gr. .914 (*F. Cod.*) or sp. gr. .894 (*P. G.*). It is brown-yellow and soluble in water and diluted alcohol.

Medical Uses.—This preparation is a concentrated and convenient form of squill. It is especially adapted for use as a diuretic. *Dose*, 3 or more minims (Gm. 0.20), largely diluted.

EXTRACTUM SCUTELLARIÆ FLUIDUM, U. S.—FLUID EXTRACT OF SCUTELLARIA.

Fluid extract of skull-cap, E.; Extrait liquide de scutellaire, Fr.; Flüssiges Helmkraut-extrakt, G.

Preparation.—Scutellaria, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 1 part of alcohol with 2 parts of water (or, by measure, 25 fluidounces of alcohol with 41 fluidounces of water), and, having moistened the powder with 35 Gm. (8 $\frac{3}{4}$ oz. av. or 8 $\frac{3}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the scutellaria is exhausted. Reserve the first 80 Ccm. (19 $\frac{1}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Made with the pharmacopœial menstruum, this newly-introduced fluid extract is of a brown color, and on keeping produces a bulky precipitate, which may be lessened by using as a menstruum 2 parts (or 22 measures) of alcohol and 1 part (or 9 measures) of water; the fluid extract will have a green-brown color.

The dose is stated at 1 or 2 fluidrachms (Gm. 4–8).

EXTRACTUM SENEGÆ FLUIDUM, U. S.—FLUID EXTRACT OF SENEGA.

Extrait liquide de polygale de Virginie, Fr.; Flüssiges Senegaextrakt, G.

Preparation.—Senega, in No. 40 powder, 100 Gm. (25 oz. av.); Water of Ammonia 2 Gm. ($\frac{1}{2}$ oz. av. or 250 minims); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts of alcohol with 1 part of water (or, by measure, 50 fluidounces of alcohol and 20 $\frac{1}{2}$ fluidounces of water), and, having moistened the powder with 45 Gm. (11 $\frac{1}{4}$ oz. av. or 12 fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the senega is exhausted. Reserve the first 85 Ccm. (20 $\frac{1}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add, first, the water of ammonia, afterward enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Water is a better solvent for senegin than a strongly alcoholic menstruum, but it has also the disadvantage of dissolving a considerable proportion of various pectin compounds, which are apt after some time to convert the liquid into a gelatinous mass. This tendency to gelatinizing is lessened by the pharmacopœial menstruum, with which the root may be exhausted without difficulty, and it is prevented by the subsequent addition of an alkali; for which purpose Dr. Squibb (1871) proposed about 2 $\frac{1}{2}$ drachms of ammonia-water, and H. N. Rittenhouse the same quantity of bicarbonate of sodium, to a pint of the fluid extract. This is dark-brown in color, and has the characteristic odor and acrid taste of the root.

Off. Prep.—Syrupus senegæ, *U. S.*

EXTRACTUM SENEGÆ.—Extract of senega, *E.*; Extrait de polygale, Extrait de séneca, *Fr.*; Senegaextrakt, *G.*—This has been dismissed from the *U. S. P.* and *P. G.*, which authorities prepared it with diluted alcohol, obtaining about 30 per cent. of extract. The French Codex orders alcohol sp. gr. .914, which yields from 16 to 20 per cent. of extract. It may be prepared extemporaneously by evaporating the fluid extract to the proper consistence.

Medical Uses.—The special object of this preparation is apparently to supersede the decoction, all of whose virtues it possesses. *Dose*, 5 to 20 minims (Gm. 0.30–1.30).

EXTRACTUM SENNÆ FLUIDUM, U. S.—FLUID EXTRACT OF SENNA.*Extrait liquide de séné, Fr.; Flüssiges Sennaextrakt, G.*

Preparation.—Senna, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 4 parts of water (or, by measure, 30 fluidounces of alcohol with $32\frac{3}{4}$ fluidounces of water), and, having moistened the powder with 40 Gm. (10 oz. av. or $10\frac{1}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the senna is exhausted. Reserve the first 80 Ccm. ($19\frac{1}{4}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

The fluid extract of 1850 was a thick syrup flavored with oil of fennel and Hoffmann's anodyne, the latter added to prevent fermentation. In 1860 these additions were dropped, and in 1870 glycerin was substituted for sugar. Properly prepared, these fluid extracts kept well, although a deposit took place, but they were inconveniently thick. The present formula yields a thinner fluid extract, which separates insoluble inert matter on the sides and bottom of the bottle. From the observation of Mr. Alonzo Robbins (1883), it appears that the addition of glycerin to the menstruum causes the precipitate to collect at the bottom. Freed from the precipitate, the fluid extract is of a dark-brown color and has the odor and taste of senna-leaves.

Medical Uses.—This fluid extract may be prescribed as a laxative in *doses* of a fluidrachm (Gm. 4), and as a purgative in doses of 2 or more fluidrachms (Gm. 8). It is apt to gripe severely without the addition of a carminative, such as oil of anise or oil of peppermint.

EXTRACTUM SERPENTARIÆ FLUIDUM, U. S.—FLUID EXTRACT OF SERPENTARIA.*Extrait liquide de serpentaire, Fr.; Flüssiges Schlangenwurz-Extrakt, G.*

Preparation.—Serpentaria, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 22 fluidounces of alcohol with 6 fluidounces of water), and, having moistened the powder with 30 Gm. ($7\frac{1}{2}$ oz. av. or $8\frac{1}{4}$ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the serpentaria is exhausted. Reserve the first 90 Ccm. ($21\frac{1}{2}$ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

There is scarcely any difference in the results obtained with this and with the formula of 1870. The virtues of serpentaria are well exhausted and properly preserved by this process. The fluid extract has a red-brown color and the peculiar odor and bitter taste of the drug.

Medical Uses.—It is a convenient and efficient substitute for the infusion of serpentaria. *Dose*, $\frac{1}{2}$ fluidrachm (Gm. 2).

EXTRACTUM SPIGELLÆ FLUIDUM, U. S.—FLUID EXTRACT OF SPIGELIA.*Extrait liquide de spigélie, Fr.; Flüssiges Spigeliextrakt, G.*

Preparation.—Spigelia, in No. 60 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 30 Gm. ($7\frac{1}{2}$ oz. av. or $7\frac{3}{4}$ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the per-

colation to proceed, gradually adding diluted alcohol, until the spigelia is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Originally, the fluid extract was saccharine, and in 1870 the sugar was replaced by glycerin. It was found, however, that it will keep unaltered in the form of a concentrated tincture, as by the present formula. It is a dark-brown liquid, fully representing the virtues of spigelia.

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM.—Fluid extract of spigelia and senna, *E.*; Extrait liquide de spigélie et séné, *Fr.*; Flüssiges Spigeliën- und Senna-Extrakt, *G.*—After 1860 this preparation was made by mixing fluid extract of spigelia 10 fluidounces with fluid extract of senna 6 fluidounces and oils of caraway and of anise each 20 minims. A more elegant and satisfactory preparation, however, is obtained, according to Mr. Alonzo Robbins (1883), by preparing it from the drugs, as originally suggested by Procter (1848), omitting the alkali; the proportions are—spigelia 60 parts (15 oz. av.), senna 30 parts (7½ oz. av.), anise and caraway each 5 parts (1¼ oz. av.); the menstruum is diluted alcohol, and the yield is 100 parts by measure (24 fluidounces).

Medical Uses.—It possesses fully the virtues of spigelia, and may be given in the dose of a fluidrachm (Gm. 4) and upward.

Fluid extract of spigelia and senna represents in a concentrated form the well-tried and popular remedy “worm tea.” It should be prescribed in doses of 1 or more fluidrachms (Gm. 4), at intervals of an hour, until it begins to purge.

EXTRACTUM STILLINGIÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF STILLINGIA.

Extrait liquide de stillingie, Fr.; Flüssiges Stillingienextrakt, G.

Preparation.—Stillingia, in No. 40 powder, 100 Gm. (25 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 30 Gm. (7½ oz. av. or 7¼ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the stillingia is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Except in the absence of glycerin, this fluid extract differs scarcely from that of 1870. It is of a dark red-brown color and has the bitterish, pungent taste of the root. A somewhat stronger alcoholic menstruum seems to improve it.

Medical Uses.—It may be employed in various chronic diseases, and especially serofula, diseases of the skin, syphilis, etc. *Dose*, ½ fluidrachm (Gm. 2).

EXTRACTUM STRAMONII, *U. S., Br.*—EXTRACT OF STRAMONIUM.

Extractum stramonii seminis, U. S. 1870.—Extract of stramonium-seed, E.; Extrait de semences de stramoine, Fr.; Stechapfelsamen-Extrakt, G.

Preparation.—Stramonium-seed, in No. 40 powder, 100 parts (20 oz. av); Diluted Alcohol a sufficient quantity. Moisten the powder with 30 parts (6 oz. av. or 6¼ fluidounces) of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until 300 parts (60 oz. av. or about 60 fluidounces) of tincture are obtained or the stramonium-seed is exhausted. Reserve the first 90 parts (18 oz. av. or about 18 fluidounces) of the percolate, evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 10 parts (2 oz. av.), mix the residue with the reserved portion in a porcelain capsule, and by means of a water-bath evaporate, at or below the before-mentioned temperature, to a pilular consistence.—*U. S.*

According to the British Pharmacopœia, the coarsely-powdered seeds are first exhausted with washed ether—in place of which petroleum benzin might be used—for removing the fixed oil; the residue is then percolated with proof spirit sp. gr. .920, the tincture dis-

tilled to recover the alcohol, and finally evaporated to the proper consistence. The yield is about $12\frac{1}{2}$ per cent. The extract of the French Codex is made by digestion with alcohol spec. grav. .914; after distilling and evaporating the tincture the residue is dissolved in four times its weight of distilled water, filtered to remove oily and resinous matter, and the filtrate evaporated to the proper consistence. The yield is about 7 per cent.

Off. Prep.—Unguentum stramonii, *U. S.*

EXTRACTUM STRAMONII FOLIORUM, *U. S. P.* 1870, was prepared from the dry leaves with alcohol and diluted alcohol; the yield is about 20 per cent. EXTRACTUM STRAMONII, *P. G.* 1872, was the inspissated juice of the fresh plant; yield, 3–3½ per cent.

Medical Uses.—Its commencing *dose* should not exceed $\frac{1}{4}$ grain (*Gm.* 0.016).

EXTRACTUM STRAMONII FLUIDUM, *U. S.*—FLUID EXTRACT OF STRAMONIUM.

Fluid extract of stramonium-seed, E.; Extrait liquide de semences de stramoine, Fr.; Flüssiges Stechapfelsamen-Extrakt, G.

Preparation.—Stramonium-seed, in No. 40 powder, 100 *Gm.* (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 *Ccm.* (24 fluidounces). Mix 3 parts of alcohol with 1 part of water (or, by measure, 37 fluidounces of alcohol with 10 fluidounces of water), and, having moistened the powder with 20 *Gm.* (5 oz. av. or 5½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the stramonium-seed is exhausted. Reserve the first 90 *Ccm.* (21½ fluidounces) of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 *Ccm.* (24 fluidounces).—*U. S.*

This is a new pharmacopœial preparation, of a brown color and the taste of the seed. Since the menstruum ordered displaces some of the fixed oil of the seed, the latter should be removed, as stated above.

Medical Uses.—The commencing *dose* should not exceed 1 or 2 minims (*Gm.* 0.06–0.12).

EXTRACTUM TARAXACI, *U. S., Br., P. G.*—EXTRACT OF TARAXACUM.

Fluid extract of dandelion, E.; Extrait de pissenlit (de dent de lion), Fr.; Löwenzahn-Extrakt, G.

Preparation.—Fresh Taraxacum, gathered in September, a convenient quantity; Water a sufficient quantity. Slice the taraxacum and bruise it in a stone mortar, sprinkling on it a little water, until reduced to a pulp; then express and strain the juice, and evaporate it in a vacuum-apparatus or in a shallow porcelain dish, by means of a water-bath, to a pilular consistence.—*U. S.*

Take of fresh dandelion-root 4 pounds. Crush the root, press out the juice, and allow it to deposit; heat the clear liquor to 212° F., and maintain the temperature for 10 minutes; then strain, and evaporate by a water-bath, at a temperature not exceeding 160° F., until the extract has acquired a suitable consistence for forming pills.—*Br.*

The juice of taraxacum contains albumen, which is very properly removed in the second process by heating the juice for a short time to the boiling-point and straining from the coagulum. Collected in the autumn, the fresh root yields 8 to 10 per cent. of extract; the fresh spring root, with the leaves, yields a smaller amount, varying between 4½ and 6 per cent., and, after drying by exhaustion with cold water, from 25 to 40 per cent. This is the extract recognized by the German Pharmacopœia, that of the French Codex being made from the fresh leaves, with a yield of 2½ to 3 per cent. The extract is of a brown color, and should yield a nearly clear solution with water.

Medical Uses.—Owing to its liability to spoil, this extract is not an eligible preparation. It may be prescribed in the *dose* of 10 grains (*Gm.* 0.60) and upward, dissolved in some aromatic water and taken after meals.

EXTRACTUM TARAXACI FLUIDUM, U. S.—FLUID EXTRACT OF TARAXACUM.

Extrait liquide de pissenlit, Fr. ; Flüssiges Löwenzahn-Extrakt, G.

Preparation.—Taraxacum, in No. 30 powder, 100 Gm. (25 oz. av.); Alcohol. Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Mix 2 parts of alcohol with 3 parts of water (or, by measure, 22 fluidounces of alcohol with 27 fluidounces of water), and, having moistened the powder with 30 Gm. (7½ oz. av. or 7½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the taraxacum is exhausted. Reserve the first 85 Cem. (20½ fluidounces) of the percolate; by means of a water-bath distil off the alcohol from the remainder, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

The present fluid extract is similar to that of 1860, except that it contains a stronger alcohol; that of 1870 contained one-fourth its measure of glycerin. On keeping, these preparations deposit a slight precipitate of inert matter. Prepared from good dandelion-root, the fluid extract is an efficient preparation, of a reddish-brown color and bitterish-sweet taste. We have seen commercial fluid extracts bearing this name which, to judge from their appearance and their more decided bitterness, were evidently made from chicory-root.

Medical Uses.—It is a more permanent preparation than the decoction of dandelion, and at the same time quite as operative. *Dose.* 1 or more fluidrachms (Gm. 4), largely diluted.

EXTRACTUM TRITICI FLUIDUM, U. S.—FLUID EXTRACT OF TRITICUM.

Fluid extract of couch-grass, E. ; Extrait liquide de chiendent, Fr. ; Flüssiges Quecken-extrakt, G.

Preparation.—Triticum, finely cut, 100 Gm. (25 oz. av.); Alcohol. Water, each a sufficient quantity; to make 100 Cem. (24 fluidounces). Pack the triticum in a cylindrical percolator and pour boiling water upon it until it is exhausted. Evaporate the percolate to 80 Cem. (19½ fluidounces), and, having added to it 20 Cem. (4½ fluidounces) of alcohol, mix well and set it aside for 48 hours. Then filter the liquid, and add to the filtrate enough of a mixture composed of 4 parts (or 13 measures) of water and 1 part (or 4 measures) of alcohol to make the fluid extract measure 100 Cem. (24 fluidounces).—U. S.

The manipulation for preparing this new fluid extract will be successful only if suitable provision be made to let the liquid pass from the percolator in drops, the drug being too coarse and unyielding to permit its packing like most of the other powders. We consider digestion preferable to percolation, since the drug is thus easily exhausted, and by shortening the process fermentation of the strongly saccharine liquid is prevented. For the reason stated, the liquid should be rapidly concentrated. The fluid extract is of a brown color and sweet taste.

EXTRACTUM GRAMINIS, P. G. Couch-grass 1 part, boiling water 5 parts: digest for 6 hours, strain, boil down to 3 parts, filter, and evaporate to the proper consistence. The yield varies between 25 and 35 per cent. The French Codex directs exhaustion with cold water, boiling, straining, and evaporating; the yield is stated to be 9 or 10 per cent.

Medical Uses.—The fluid extract diluted with water or added to some emollient infusion, such as that of flaxseed or of barley, may be freely used in irritations of the genito-urinary tract, of the intestinal canal, of the bronchia, etc. A decoction of the fresh plant is to be preferred.

EXTRACTUM UVÆ URSI FLUIDUM, U. S.—FLUID EXTRACT OF UVA URSI.

Extrait liquide de busserole, Fr. ; Flüssiges Bärentraubenblätter-Extrakt, G.

Preparation.—Uva Ursi, in No. 30 powder, 100 Gm. (25 oz. av.); Glycerin 10 Gm. (2½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 Cem. (24 fluidounces).

Mix the glycerin with 90 Gm. (22½ oz. av. or 23½ fluidounces) of diluted alcohol, and, having moistened the powder with 35 Gm. (8¼ oz. av. or 8½ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the *uva ursi* is exhausted. Reserve the first 70 Ccm. (16¾ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Except in the reduction of the glycerin and a slight increase of the alcoholic strength, this fluid extract does not differ from that of 1870. It is of a dark-brown color and has the bitter and astringent taste of the leaves.

Medical Uses.—It probably possesses all the virtues of the plant. Like nearly all medicines intended to act upon the urinary organs, it should be given largely diluted. *Dose*, a fluidrachm (Gm. 4).

EXTRACTUM VALERIANÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF VALERIAN.

Extrait liquide de valériane, Fr.; *Flüssiges Baldrian-Extrakt*, G.

Preparation.—Valerian, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts (22 fluidounces) of alcohol with 1 part (9 fluidounces) of water, and, having moistened the powder with 30 Gm. (7½ oz. av. or 7¾ fluidounces) of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the valerian is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

Experience has shown that the stronger alcoholic menstruum of the previous pharmacopœias is not necessary for the preservation of this fluid extract. As now made, it is of a deep red-brown color and of the characteristic odor and taste of valerian. If the percolation and the evaporation of the weak tincture have been well managed, but little loss of volatile oil will occur.

EXTRACTUM VALERIANÆ has been dismissed from most pharmacopœias. The French Codex directs it to be made with alcohol sp. gr. .914; the yield is 19 or 20 per cent. It may be readily prepared by concentrating the fluid extract at the heat of a water-bath.

Medical Uses.—An efficient preparation of this valuable drug. *Dose*, 1 fluidrachm (Gm. 4).

EXTRACTUM VERATRI VIRIDIS FLUIDUM, *U. S.*—FLUID EXTRACT OF VERATRUM VIRIDE.

Fluid extract of American veratrum, E.; *Extrait liquide de vétrate américain*, Fr.; *Flüssiges Grüngermer-Extrakt*, G.

Preparation.—Veratrum Viride, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 30 Gm. (7½ oz. av. or 8¾ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the veratrum viride is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—*U. S.*

No change has been made except in manipulation. The resins and alkaloids are readily taken up and held in solution by the menstruum directed, and the fluid extract is therefore about double the strength of the tincture of the same drug.

Medical Uses.—This preparation is a very potent depressor of the heart's action. *Dose*, 1 to 3 minims (Gm. 0.05–0.15).

EXTRACTUM VIBURNI FLUIDUM, U. S.—FLUID EXTRACT OF VIBURNUM.

Fluid extract of blackhaw-bark, E.; *Extrait liquide de viburne*, Fr.; *Flüssiges Viburnum-extrakt*, G.

Preparation.—Viburnum, in No. 60 powder, 100 Gm. (25 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 Ccm. (24 fluidounces). Mix 2 parts (22 fluidounces) of alcohol with 1 part (9 fluidounces) of water, and, having moistened the powder with 30 Gm. (7½ oz. av. or 8 fluidounces) of menstruum, pack it moderately in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the viburnum is exhausted. Reserve the first 85 Ccm. (20½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

A newly-introduced fluid extract of a deep brown-red color and of the astringent and bitter taste of the bark.

Medical Uses.—Doubtless this preparation represents the undetermined virtues of viburnum. *Dose*, 30 to 60 minims (Gm. 2–4).

EXTRACTUM XANTHOXYLI FLUIDUM, U. S.—FLUID EXTRACT OF XANTHOXYLUM.

Fluid extract of prickly ash, E.; *Extrait liquide d'écorce de clavier*, Fr.; *Flüssiges Zahnwehrindenextrakt*, G.

Preparation.—Xanthoxylum, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 25 Gm. (6½ oz. av. or 7½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the xanthoxylum is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

A newly-introduced fluid extract of a reddish-brown color, and possessing the acrid taste of the bark.

Medical Uses.—It is probable that this preparation contains all the active constituents of xanthoxylum. Its *dose* is stated to be from ½ to 1 fluidrachm (Gm. 2–4).

EXTRACTUM ZINGIBERIS FLUIDUM, U. S.—FLUID EXTRACT OF GINGER.

Extrait liquide de gingembre, Fr.; *Flüssiges Ingwer-Extrakt*, G.

Preparation.—Ginger, in No. 40 powder, 100 Gm. (25 oz. av.); Alcohol a sufficient quantity; to make 100 Ccm. (24 fluidounces). Moisten the powder with 25 Gm. (6½ oz. av. or 7½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the ginger is exhausted. Reserve the first 90 Ccm. (21½ fluidounces) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure 100 Ccm. (24 fluidounces).—U. S.

Ginger is readily exhausted by alcohol; the brownish-red fluid extract is between five and six times stronger than the tincture of ginger, and has the same sensible properties, but in a higher degree. It is used in preparing Syrupus zingiberis, U. S.

Medical Uses.—It is a convenient substitute for the tincture on account of its

greater strength, and for the infusion on account of its small bulk. *Dose*, 10 or more minims (Gm. 0.60).

FARINA TRITICI, *Br.*—WHEATEN FLOUR.

Wheat flour, E.; *Farine de froment*, *Farine de blé*, Fr.; *Weizenmehl*, G.

The grain of wheat, *Triticum vulgare*, Villars, s. Tr. sativum, Lamarck, ground and sifted. Bentley and Trimen, *Med. Plants*, 294.

Nat. Ord.—Graminaceæ.

Origin.—An annual or biennial herbaceous plant which, though now unknown in the wild state, is probably indigenous to Central Asia, but has been under cultivation from a very early period, and is at present raised in most countries of the temperate zones. The smooth and jointed stem (culm) is 3 to 5 feet (0.9 to 1.5 M.) high; the leaves are long, linear, somewhat rough; the terminal spikes are 3 to 4 inches (37 to 50 Mm.) long, with a flat and finely hairy axis (rachis), and four- or five-flowered, flattened spikelets, producing usually three fruits, which are oval-oblong, obtuse, grooved on the upper side, and of a yellowish or brownish color. Numerous varieties have been produced by cultivation, some having the chaff awnless or the lower paleæ more or less awned and the fruit of a white or reddish color. Spring or summer wheat (Tr. æstivum) is awned or bearded, winter wheat (Tr. hybernum) mostly awnless.

Of other species of wheat which are cultivated the following may be mentioned: *Trit. turgidum*, Linné, of which Tr. compositum, or Egyptian wheat, is a variety with compound spikes; Tr. durum, Desfontaines, or *horny wheat*, with long awns, including the varieties villosum, hordeiforme, and others; Tr. Spelta, Linné, or *spelt*, with triangular ovate and obtuse grains, which are little mealy, and Tr. monococcum, Linné, or *one-grained wheat*, with small spikes and three flowers in each spikelet, two being barren, the third one producing a somewhat triangular grain.

Wheat grain, like the similar graminaceous fruits, has the integuments of the fruit and seed united; underneath this covering is a layer of cells containing *gluten*, and then follows the cellular tissue of the so-called albumen or perisperm, this being filled with numerous *starch-granules*. Wheat is most generally prepared for food by grinding, and separating by means of sieves the broken integuments, or *bran*, from the fine amylaceous white portion, or *flour*.

Description.—Wheaten flour is a very fine white powder, without odor and of an insipid taste. The starch-granules, which largely compose it, have been described on page 195.

Composition.—Air-dry wheat contains, according to Millon (1854), 12 to 17 per cent. of water, 8 to 16 per cent. of gluten, about 2 per cent. of fat, about 2 per cent. of cellulose, and 1½ to 2 per cent. of ash. Older analyses of different kinds of wheat were principally made by A. Vogel (1818), Proust (1820), and Henry and Vauquelin (1822). The amount of starch varies between 60 and 70 per cent., and the weight of nitrogen between 1.6 and 2.7 per cent. A small quantity of saccharine matter is also present, and the ash contains nearly 50 per cent. of phosphoric acid. The inorganic constituents are mostly found in the bran, to the extent of over 7 per cent., while the nitrogenated principles enter chiefly the flour. If the latter be kneaded with cold water as long as the liquid becomes milky, a yellowish-gray elastic and glutinous mass remains, which is the *gluten* of Beccaria, retains about 70 per cent. of water, and consists, according to Von Bibra, in the dry state of about 70 per cent. *vegetable fibrin*, 3.8 to 9.3 *vegetable casein*, 7.5 to 19.5 *glutin*, and 4.6 to 8.2 per cent. of fat. When fresh it dissolves in dilute phosphoric acid and in solution of potassa. On drying it assumes a hornlike appearance and partly loses its solubility. According to Boussingault, it contains 15 per cent. of nitrogen.

To purify it, Ritthausen (1862-67) dissolves it in cold very dilute potassa solution (1 to 1000 parts of water), decants from the undissolved starch, and precipitates with acetic acid. The precipitate is repeatedly treated with fresh portions of alcohol, commencing with spec. gr. .914, and increasing the strength finally to absolute alcohol. After another washing with ether the insoluble portion constitutes *gluten-casein*, which is slightly soluble in acetic acid, freely soluble in potassa, and becomes insoluble by heat. On evaporating the united alcoholic liquids to one-half and cooling, *gluten-fibrin* is separated, which is freed from adhering casein by dissolving it repeatedly in 60 and 70 per cent. alcohol. It is freely soluble in dilute acetic acid, and when boiled with water, in which it is insoluble, it is converted into a jelly. After the separation of gluten-fibrin the greater portion

of the alcohol is evaporated; the precipitate appearing on cooling is treated with a little alcohol, washed with ether, dissolved in a little 65 per cent. alcohol, and precipitated by absolute alcohol. The precipitate is *mucedin*; the solution contains *glutin* or *gliadin*. The former yields with cold or boiling water a milk-like liquid; the latter is soluble in water, alcohol, acetic acid, potassa, etc., the aqueous solution being precipitated by the salts of the heavier metals; *glutin* contains sulphur and 18 per cent. of nitrogen. These principles are the most important ones of the *vegetable protein compounds*.

Off. Prep.—Cataplasma fermenti, *Br.*

Medical Uses.—Wheaten flour is often used as a dusting-powder to allay the heat and pain of local inflammations, such as superficial *burns* and *scalds*, *erysipelas*, *erythema*, *intertrigo*, *prickly heat*, etc. But it is very far inferior for such purposes to powdered starch. Its dietetic uses need not here be considered, but one among them, which is also partly medicinal, is worthy of notice: it is the administration of an uncooked paste made from wheaten flour in many cases of *diarrhœa*, and especially in those depending upon debility. The summer diarrhœas of this climate are usually curable by this simple remedy if the patient rests and abstains from other food.

FEL BOVIS, U. S.—OX-GALL.

Fel borinum, *Fel tauri*, *Bilis bubula*.—*Ox-bile*, E.; *Fiel (Bile) de bœuf*, Fr.; *Ochsen-galle*, *Rindsgalle*, G.

The fresh gall of *Bos Taurus*, *Linné*.

Class Mammalia. Order Ruminantia.

Origin and Properties.—Bile is a green or brownish-green viscid, transparent, or more frequently translucent, liquid which is separated by the liver in the gall-bladder; it has a peculiar odor, which becomes prominent on heating, a nauseous, sweet, and bitter taste, a specific gravity of about 1.02, a slight alkaline or sometimes a neutral reaction, and dissolves completely when agitated with water. On warming it becomes thinner, and may then be readily strained through moistened muslin, whereby fragments of tissue, epithelial cells, etc. are removed. When mixed with its own weight or twice its bulk of alcohol a precipitate is produced in fresh bile consisting almost exclusively of mucilaginous matter, and the liquid filtered from it and freed from alcohol by evaporation resists putrefaction for a long time.

Constituents.—The principal coloring matter of bile appears to be *bilirubin*, formerly called *coperyrrhin*, $C_{42}H_{58}N_2O_6$, which is slightly soluble in alcohol and ether, but dissolves in chloroform, bisulphide of carbon, and benzol; it forms an amorphous or crystalline orange-colored or red powder. It is accompanied by *bilifuscin*, a dark olive-brown powder soluble in alcohol and in hot chloroform; *biliprasin*, a green-black powder insoluble in chloroform, soluble in alcohol, with a green, or in the presence of ammonia with a brown, color; and *bilihumin*, a blackish powder insoluble in simple solvents and often found in biliary concretions. *Biliverdin*, formed by the oxidation of bilirubin, is a dark-green powder soluble in alcohol with a green color and insoluble in water, ether, and chloroform (Städeler, 1864). The fatty matter of bile is chiefly *cholesterin*, $C_{26}H_{44}O$, which is also an ingredient of the brain, the nerves, the yolk of eggs, etc. It crystallizes in colorless laminae or prisms, is unchanged by boiling potassa, dissolves in ether, chloroform, and hot alcohol, and is chemically a monatomic alcohol. Ox-gall contains about 3 per cent. each of the sodium salts of two peculiar acids, named *glycocholic* (the *cholic acid* of some older authors) and *taurocholic* (Strecker's *choleic acid*), a part of the former of which, together with the remaining pigments, is precipitated by neutral acetate of lead from fresh bile previously decolorized by animal charcoal. When to the filtrate from this precipitate subacetate of lead is carefully added until the insoluble compound formed has a white color, the precipitate will consist of glycocholate and taurocholate of lead, and the filtrate contains only taurocholic acid, which is precipitated on the further addition of basic acetate of lead. Hüfner (1874) observed that glycocholic acid usually crystallizes out when fresh beef-gall is mixed with an excess of hydrochloric acid and ether. Emich (1882) prefers the use of benzol in the place of ether, and ascertained that in those cases where crystals are not obtained by this treatment the glycocholate has been reduced to about $\frac{3}{4}$ per cent. and the taurocholate increased to about $5\frac{1}{2}$ per cent. Glycocholic acid, $C_{26}H_{43}NO_6$, is in very fine white needles of a silky lustre and a sweetish-bitter taste. At 20° C. (68° F.) it requires for solution 11,100 parts of benzol, 9090 parts of chloroform, 1075 parts of ether, 36.3 parts of 50 per cent. alcohol or 3030 parts of water, but is much more soluble in solutions of taurocholic acid. On being boiled with acids it

is converted into insoluble *paraglycocholic acid*, melting at 183°C . (361.4°F .), while glycocholic acid melts at 132°C . (269.6°F .). Its salts have a sweet taste and are mostly soluble in water and alcohol. Boiled with alkalis, it takes up 1 molecule of water and splits into *glycochol* (*glycin* or *amidocacetic acid*), $\text{C}_2\text{H}_5\text{NO}_2$, and *cholic acid* (*cholalic acid* of Strecker), $\text{C}_{26}\text{H}_{46}\text{O}_5$, which has a bitter and afterward sweetish taste. *Taurocholic acid*, $\text{C}_{26}\text{H}_{46}\text{NSO}_7$, is in silky acicular crystals easily soluble in water and alcohol, and when boiled with alkalis decomposed into *cholic acid* and *taurin* (*amido-isethionic acid*), $\text{C}_2\text{H}_7\text{NSO}_3$.

Ox-bile contains the two biliary acids in nearly equal proportions; human bile mainly taurocholic acid, which is found in dog-bile almost to the exclusion of other acids. Both acids, dissolved in water and mixed with a little syrup and afterward with oil of vitriol, acquire a red color, changing to carmine, purple, and violet (*Pettenkofer's test for bile*). Using syrupy phosphoric in place of sulphuric acid, Drechsel (1881) observed that the reaction is less interfered with by an excess of sugar. Cholic acid shows a similar behavior, and the coloration is also obtained with unpurified bile, and with glucose as well as cane-sugar; according to Van den Broek (1846), the principal constituents of bile give the reaction with sulphuric acid without the previous addition of sugar.

Pharmaceutical Preparations.—*FEL BOVIS INSPISSATUM*, *U. S.*; *EXTRACTUM FELLIS BOVINI*.—Inspissated ox-gall, *E.*; Fiel épaissi, Extrait de bile de bœuf, *Fr.*; Eingedickte Rindsgalle, *G.*—Fresh ox-gall 100 parts; to make 15 parts. Heat the ox-gall to a temperature not exceeding 80°C . (176°F .); strain it through muslin, and evaporate the strained liquid, on a water-bath in a porcelain capsule, to 15 parts.—*U. S.* By this process the fragments of tissue present in bile are strained off and the water is mostly evaporated. Following strictly the letter of the pharmacopœial directions, the product must vary in consistence and permanence. The French Codex more properly directs the evaporation to be continued until a firm extract is obtained; the yield is from 11 to 13, or sometimes 15, per cent.

FEL BOVIS PURIFICATUM, *U. S.*; *FEL BOVINUM PURIFICATUM*, *Br.*; *FEL TAURI DEPURATUM*.—Purified ox-gall or ox-bile, *E.*; Fiel de bœuf purifié, Bile purifié, *Fr.*; Gereinigte Ochsen-galle, *G.*—Fresh ox-gall 3 parts (30 oz. av.); Alcohol 1 part (10 oz. av. or $11\frac{1}{2}$ fluidounces). Evaporate the ox-gall in a porcelain capsule on the water-bath to 1 part (10 oz. av.); then add to it the alcohol, agitate the mixture thoroughly, and let it stand, well covered, for 24 hours. Decant the clear solution, filter the remainder, and, having mixed the liquids and distilled off the alcohol, evaporate to a pilular consistence.—*U. S.* The British Pharmacopœia directs fresh ox-bile 1 pint to be precipitated with rectified spirit 2 pints; the remainder of the process is identical with the foregoing. The object is the removal of the mucilage, whereby ox-gall is rendered less prone to change.

Both preparations are deep yellowish-green extract-like masses having the peculiar odor, taste, and behavior of bile, and being completely soluble in water. Only purified ox-gall is completely soluble in spirit, and its aqueous solution is not precipitated by alcohol.

The German Pharmacopœia of 1872 directed a still purer article, from which, besides the mucilage, the biliary coloring matters also have been removed; the decolorization is effected after the removal of the mucilage by distilling off the alcohol and then adding to the residue recently-purified and well-washed still moist animal charcoal; 8 to 10 parts of it will be sufficient for 100 parts of bile. The mixture is occasionally agitated, and when the liquid shows only a slight yellow color it is passed through a moistened filter, evaporated in a porcelain capsule by means of a water-bath, and then completely exsiccated in a drying closet or by means of a sand-bath, the heat of which must not be allowed to rise above 100°C . (212°F .). If spread upon glass plates it may be sealed, or the dry mass is reduced to powder and preserved in small well-corked vials. The yield is nearly 7 per cent. It forms a yellow or yellowish-white powder, which attracts moisture from the atmosphere and dissolves completely in water and alcohol, the solutions being of a yellowish color and of the sweet and bitter taste of bile. When heated to redness it burns, leaving a small amount of a white alkaline ash. This preparation is sometimes sold as *choleate* or *choleinate of sodium*.

Physiological Action.—The function of the bile is far from being thoroughly understood, for its composition is exceedingly complex, but, along with the pancreatic juice, it seems intended to neutralize the acidity of the chyme received by the duodenum from the stomach, and at the same time to emulsify the fatty matters which the acid secretions of the stomach are not fitted to prepare for absorption. It is further probable

that the excess of bile not so employed tends to quicken the peristaltic movements of the bowels. It is at least pretty certain that when the bile is profusely secreted it occasions diarrhoea. It is quite certain that in doses of from half an ounce to an ounce fresh ox-bile acts as a laxative, and that if its use be persisted in it is very apt to excite a burning sensation in the rectum and to induce hæmorrhoids. On the other hand, it is a familiar fact that when from any cause bile enters the stomach from the intestine it occasions loss of appetite, nausea, and even vomiting—for the reason, doubtless, that it neutralizes the gastric juice, which during healthy digestion is always strongly acid. In this way, probably, it may impair or wholly prevent the gastric digestion of starchy food. There is no physiological probability nor any clinical evidence to show that bile, however introduced into the stomach, can promote in any way the digestion of food in that organ. That when administered medicinally it may, on reaching the duodenum, reinforce the action of the bile secreted there, is indeed probable. When the latter secretion, therefore, is deficient, it may tend to prevent the fermentative and putrefactive decomposition of the food, aid in the solution of its fatty constituents, promote the peristaltic action of the intestine, and in a sufficient dose provoke purgation.

Medical Uses.—Ox-gall (or pig-gall, which is supposed to be more analogous to human bile) is thought to be an efficient remedy for habitual *constipation* depending upon atony of the intestine. After its use the bowel is not so apt to become torpid as after the use of ordinary purgatives. It is perhaps of some interest to note that the medicine which most nearly resembles it in this respect is aloes, which, like bile, is very bitter and tends to irritate the rectum. The *dyspeptic* derangements which are apt to attend constipation, and which often depend upon a distended colon compressing the liver or its ducts, usually subside under purgation of any kind. It is very doubtful if ox-gall exhibits any of the special virtues which have been attributed to it under these circumstances. In *jaundice* depending upon catarrh of the bile-ducts this medicine is sometimes found advantageous, probably in virtue both of its purgative operation and of its supplying for duodenal digestion the agent which the liver fails to secrete. The objection to its use, that it will be absorbed into the blood already overcharged with bile, is more specious than sound. Bile has been used as a *vermifuge* for lumbricoid ascarides. As a topical remedy it has been applied with alleged success to the treatment of various *glandular* hypertrophies and indurations, but this method has not been accepted.

The administration of bile in a liquid state is too disgusting to be recommended. It may be given in the form of inspissated bile, which is official. 5 grains of this preparation are estimated to be equal to 100 grains of fresh bile. It may be made into pills coated with gelatin or enclosed in gelatin capsules. If taken after meals this coating delays the escape of the bile until the food is ready to pass through the pylorus. About 10 grains (Gm. 0.60) may be given at a dose.

FERRI ARSENIAS, Br.—ARSENATE OF IRON.

Ferrum arsenicum, Arsenias ferrosus.—*Ferrous arseniate*. E.; *Arséniate de fer*, Fr.; *Arsensaures Eisen*, G.

Formula $3\text{Fe}(\text{FeO})\text{AsO}_4 \cdot 16\text{H}_2\text{O}$. Molecular weight 1088.1.

Preparation.—Take of Sulphate of Iron 9 ounces; Arseniate of Soda, dried at 300°F ., 4 ounces; Acetate of Soda 3 ounces; boiling Distilled Water a sufficiency. Dissolve the arseniate and acetate of soda in two pints, and the sulphate of iron in 3 pints, of the water; mix the two solutions, collect the white precipitate which forms on a calico filter, and wash until the washings cease to be affected by a dilute solution of chloride of barium. Squeeze the washed precipitate between folds of strong linen in a screw press, and dry it on porous bricks in a warm air-chamber whose temperature shall not exceed 100°F .—*Br*.

On mixing solutions of ferrous sulphate and the official disodium arseniate a white precipitate takes place, which is a mixture of ferrous arseniate ($\text{Fe}_3\text{As}_2\text{O}_8$) and ferrous hydrarseniate ($\text{FeH}_4\text{As}_2\text{O}_8$). In the presence of sodium acetate, however, only the former is precipitated, and free acetic acid is found in the liquid, besides sulphate of sodium. The reaction occurs as follows: $3\text{FeSO}_4 + 2\text{Na}_2\text{HAsO}_4 + 2\text{NaC}_2\text{H}_3\text{O}_2 = \text{Fe}_3\text{As}_2\text{O}_8 + 2\text{HC}_2\text{H}_3\text{O}_2 + 3\text{Na}_2\text{SO}_4$. The white precipitate is very bulky, and while being washed to free it from the mother-liquor and dried it is oxidized and converted into ferrous-ferrie arseniate of the formula given above (Wittstein, 1866). The change is indicated by the gradual disappearance of the white color until the salt finally becomes olive-

green or blue-green. In the reaction and final result the process corresponds nearly with the one for the blue phosphate of iron.

Properties.—Arseniate of iron is a green or blue-green amorphous powder insoluble in water and alcohol, but dissolving readily in dilute hydrochloric acid, yielding a bright-yellow solution in which blue precipitates are produced with both ferrocyanide and ferridcyanide of potassium, and which yields with sulphuretted hydrogen first a milkiness (sulphur) and afterward a yellow precipitate of sulphide of arsenic. It contains 31.68 per cent. of As_2O_3 and 26.4 per cent. of water, most of which is expelled when heated to 100°C . (212°F .), the remainder being given off at a red heat without loss of arsenic. It may be distinguished from phosphate of iron, which resembles it in appearance, by boiling a small portion with an excess of caustic soda, filtering and neutralizing exactly with nitric acid, when a brick-red precipitate of arseniate of silver will be produced on the addition of silver nitrate. Phosphate of iron similarly treated yields a yellow precipitate. To determine the amount of ferrous salt, which theoretically corresponds to 19.82 per cent. of ferrous oxide, the British Pharmacopœia directs the dissolving of 20 grains in an excess of diluted hydrochloric acid, and adding thereto, gradually, volumetric solution of bichromate of potash until a drop of the acid solution ceases to give a blue precipitate with potassium ferrideyanide; at least 170 grain-measures of the test solution are required for the purpose, indicating 18 per cent. of FeO .

Medical Action and Uses.—It is difficult to conjecture on what grounds this compound was made officinal, since the proportion of iron contained in $\frac{1}{18}$ gr. (Gm. 0.004), the dose of it recommended, is too inconsiderable to have any curative action. Iron and arsenic are, both of them, medicines the dose of which must vary greatly and frequently with the nature of the disease and the special condition of the patient, and it is better that they should be given separately. To any liquid preparation of iron the solution of potassium arsenite may be added at the time of administration. The arseniate of iron may be given in a pill, and in the dose of $\frac{1}{20}$ grain (Gm. 0.003), gradually increased to $\frac{1}{2}$ grain (Gm. 0.03).

FERRI BROMIDUM.—BROMIDE OF IRON.

Ferrum bromatum.—*Ferrous bromide*, E.; *Bromure ferreux*, Fr.; *Eisenbromür*, *Ferro-bromid*, G.

Formula FeBr_2 . Molecular weight 215.

Preparation and Properties.—It is prepared by gradually adding 2 parts of bromine to 1 part of iron filings or wire and 10 parts of water, and digesting until the liquid has a greenish color, when it is filtered and evaporated in an iron dish to dryness. It forms a grayish-black mass which, on exposure to air, acquires a brown color through oxidation. From its hot concentrated solution in water it may be obtained in transparent pale-green rhombic plates of the composition $\text{FeBr}_2 \cdot 6\text{H}_2\text{O}$. On being heated to redness in contact with the atmosphere it is converted into ferric oxide and ferric bromide, the latter subliming in yellow scales. An aqueous solution of bromide of iron, preserved by sugar, has been proposed as a convenient preparation. (See SYRUPUS FERRI BROMIDI.)

Physiological Action and Medical Uses.—5 grains of this substance dissolved in 2 drachms of water and injected into a dog's jugular vein occasioned dilated pupils, spasmodic twitching, and death in 10 minutes; 10 grains introduced in the same manner produced a general tetanic spasm, in which the animal died. In both cases the veins were engorged, the heart was distended with coagula, and its irritability was very faint. Half a drachm thrown into the stomach brought on violent vomiting, dilatation of the pupils, rapid pulse and respiration, and diarrhœa with dark stools. Signs of inflammation were found in the lungs and stomach.

It may seem singular that two agents so physiologically antagonistic as iron and bromine should have been united in the same medicine, since the one tends to produce what the other is employed to subdue. Practically, however, the bromine of the compound is its only active element, as may be inferred from the experiments just related. This preparation has been recommended as an energetic astringent and anti-strumous medicine, and has been prescribed in *hypertrophy* of the heart and uterus, for *scrofulous glandular swellings*, both topically and internally, in *spermatorrhœa*, *blenorrhœa*, *leucorrhœa*, *hysteria*, *chorea*, and pulmonary *phthisis*. It has been given in doses of from $\frac{1}{2}$ grain to 2 grains (Gm. 0.3–0.12). There is not the slightest evidence of its ever having been useful as a medicine, and, as it is dangerously poisonous, it ought never to be used inter-

nally. It is now, says Husemann, entirely obsolete, and Trousdale and Pidoux pronounce it unworthy of special notice.

FERRI CARBONAS SACCHARATUS, *U. S.*, *Br.*—SACCHARATED CARBONATE OF IRON.

Ferrum carbonicum saccharatum, *P. G.*; *Carbonas ferrosus saccharatus*.—*Saccharated ferrous carbonate*, *E.*; *Saccharure de proto-carbonate de fer (de carbonate ferreux)*. *Fr.*: *Zuckerhaltiges Ferrocarbonat*, *G.*

Formula of ferrous carbonate $\text{FeCO}_3 \cdot \text{H}_2\text{O}$. Molecular weight 133.9.

The mixture of ferrous carbonate with sugar contains 20.5 per cent. *Br.*, 10 per cent. *P. G.*, 9.67 per cent. *U. S.*, of iron.

Preparation.—Sulphate of iron 10 parts; Bicarbonate of Sodium 7 parts; Sugar, in fine powder, 16 parts; Distilled Water a sufficient quantity. Dissolve the sulphate of iron in 40 parts of hot distilled water and the bicarbonate of sodium in 100 parts of warm distilled water, filter the solutions separately and allow them to cool. Add the solution of sulphate of iron gradually to the solution of bicarbonate of sodium contained in a capacious flask, and mix thoroughly by shaking. Fill up the flask with boiling distilled water and set the mixture aside for 2 hours. Draw off the supernatant liquid from the precipitate by means of a siphon, and then fill the flask again with hot distilled water and shake it. Pour off the clear liquid, and repeat the operation until the decanted liquid gives but a slight turbidity with test solution of chloride of barium. Transfer the drained precipitate to a porcelain capsule containing the powdered sugar, and mix intimately; evaporate the mixture to dryness by means of a water-bath, and reduce the product to powder. Keep the powder in small, well-stopped vials.—*U. S.* Using ounces for parts, the yield will be $20\frac{3}{4}$ ounces.

Both the British and German Pharmacopœias mix the iron and alkali solutions while hot, and thereby avoid absorption of oxygen during cooling; in other respects the manipulation does not materially differ. For 10 parts of ferrous sulphate there are ordered 7 parts of sodium bicarbonate, *P. G.*, $6\frac{1}{2}$ parts of ammonium carbonate, *Br.*; and the ferrous carbonate thus obtained is mixed with sugar 5 parts. *Br.* (yield $9\frac{1}{4}$ parts)—first with milk-sugar 2 parts and sugar 6 parts—and when dry with sufficient sugar to make 20 parts, *P. G.*

Ferrous sulphate and sodium bicarbonate decompose each other, forming ferrous carbonate, carbonic acid gas, and sodium sulphate; thus: $\text{FeSO}_4 + 2\text{NaHCO}_3 = \text{FeCO}_3 + \text{CO}_2 + \text{H}_2\text{O} + \text{Na}_2\text{SO}_4$. The operation must be performed with the air as much excluded as possible; hence the importance of employing boiling water from which the air has been expelled, of generating carbonic acid gas during the operation by the use of sodium bicarbonate, of performing the washing by decantation in deep cylindrical and well-covered vessels, and of collecting and draining, or, as directed by the *Br. P.*, expressing the precipitate rapidly; the subsequent addition of the sugar will, in a measure, protect it against oxidation until it has been finally dried.

Properties.—Ferrous carbonate forms small lumps or a gray or greenish-gray inodorous powder having a neutral reaction to moistened litmus-paper and a sweet taste like that of sugar, followed by a very feeble chalybeate taste. On exposure to dry air it is slowly, or in damp air rapidly, oxidized, and is therefore best preserved in small well-filled and sealed vials; if it has changed to a brown color and effervesces only slightly with acids, it should be rejected. When heated in contact with the air it becomes black, evolving the odor of burning sugar, and is finally converted into red-brown ferric oxide. Water dissolves only the sugar, but the powder is completely dissolved with effervescence in dilute hydrochloric acid, and this solution gives blue precipitate with both potassium ferricyanide and ferrocyanide, showing the presence of ferrous and of ferric salt. Pure ferrous carbonate contains 53.7 per cent. of ferrous oxide; the anhydrous salt, FeCO_3 (mol. weight 115.9), represents 62.07 per cent. of the oxide.

Tests.—The powder, placed upon moistened red litmus-paper, should not change the red color to blue (absence of alkali). The solution in diluted hydrochloric acid should yield no precipitate or but a slight turbidity with chloride of barium, indicating only traces of sulphate left behind from the mother-liquor. "If 8 Gm. of the saccharated carbonate of iron be dissolved in water with an excess of hydrochloric acid, and the solution mixed with 33 Ccm. of the volumetric solution of bichromate of potassium, the mixture should still afford a blue color or precipitate with test-solution of ferricyanide of potassium (presence of at least 15 per cent. of anhydrous ferrous carbonate)."—*U. S.*

The quality indicated requires, however, 34.5 (not 33) Ccm. of the volumetric solution. The British Pharmacopœia demands 36.24 per cent. of anhydrous ferrous carbonate, so that 2 Gm. of this preparation is oxidized by 20.8 Ccm. (or 20 grains by 208 grain-measures) of the volumetric solution of potassium bichromate. If none of the iron had been peroxidized, the powder would contain 20.09 per cent. U. S., 20.85 per cent. P. G., 42.8 per cent. Br., of anhydrous ferrous carbonate. The German Pharmacopœia determines the total iron only.

Off. Prep.—*Pilula ferri carbonatis, Br.*

Medical Action and Uses.—This preparation is intended to take the place of the subcarbonate, one of the oldest pharmaceutical preparations of iron, and which was intended to be a substitute for rust of iron, which from time immemorial had been used in medicine. It is one of the most employed members of its class, and may be recommended in all forms of *anæmia* and *anæmic chlorosis*, and in *neuralgia*, *chorea*, and other nervous affections depending upon a deficiency of red corpuscles in the blood. In large doses, mixed with water, it may be resorted to when the hydrated peroxide cannot be procured in cases of poisoning by *arsenious acid*. The dose is 5 grains (Gm. 0.30) and upward.

FERRI CHLORIDUM, U. S.—CHLORIDE OF IRON.

Ferrum sesquichloratum, P. G.; *Ferrum muriaticum oxydatum*, *Chloridum vel Chlorurum ferrium*, *Ferri perchloridum*.—*Sesquichloride (Perchloride) of iron*, *Ferric chloride*, E.; *Perchlorure de fer*, *Chlorure ferrique*, Fr.; *Eisenchlorid*, G.

Formula $\text{Fe}_2\text{Cl}_6 \cdot 12\text{H}_2\text{O}$. Molecular weight 540.2.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 15 parts (1½ oz. av.); Hydrochloric Acid 86 parts (9½ oz. av.); Nitric Acid, Distilled Water, each a sufficient quantity. Put the iron wire into a flask capable of holding double the volume of the intended product; pour upon it 54 parts (6 oz. av.) of hydrochloric acid previously diluted with 25 parts (2½ oz. av.) of water, and let the mixture stand until effervescence ceases; then heat it to the boiling-point, filter through paper, and, having rinsed the flask and iron wire with a little boiling distilled water, pass the rinsings through the filter. To the filtered liquid add 27 parts (3 oz. av.) of hydrochloric acid, and pour the mixture slowly and gradually, in a stream, into 8 parts (1 oz. av.) of nitric acid contained in a capacious porcelain vessel. After effervescence ceases apply heat, by means of a sand-bath, until the liquid is freed from nitrous odor and ceases to yield a blue precipitate with test solution of ferrieyanide of potassium. Should this reagent produce a blue color, add a little more nitric acid and evaporate off the excess. Then add the remaining 5 parts (½ oz. av.) of hydrochloric acid and enough distilled water to make the whole weigh 60 parts (6¾ oz. av.), and set this aside, covered with glass, until it forms a solid crystalline mass. Lastly, break it into pieces, and keep the fragments in a glass-stoppered bottle, protected from light.—U. S.

In making this salt an excess of iron is advantageously used to facilitate the saturation of the first portion of hydrochloric acid; the metal, in combining with the chlorine of the acid, will produce ferrous chloride, FeCl_2 , hydrogen being given off. The whole liquid should be passed through a paper filter, and the filtrate at once mixed with hydrochloric acid, exactly equal to one-half of the first portion, to prevent the deposition of ferric oxychloride, which would be formed by the oxidizing influence of the atmospheric air. The mixture may now be heated to near boiling, and the nitric acid poured in small portions down the side of the porcelain capsule, and the mixture continually stirred; or, to avoid loss of hydrochloric acid, the cold acid solution is now directed to be poured into nitric acid, when effervescence will commence and the oxidation be completed on applying heat. The extrication of the red vapors causes the liquid to froth considerably, hence the necessity of using a capsule holding at least three times the measure of the liquid. Diehl (1867) prefers to heat about three-fourths of the nitric acid, and to add to it gradually the hot mixture of ferrous chloride and hydrochloric acid, afterward more nitric acid as required; frothing is avoided by this manipulation. The object of this part of the process is to transform the ferrous into ferric chloride: the hydrochloric and nitric acids react upon each other, with the production of chlorine, which unites with the ferrous chloride, and of nitric oxide, which escapes, water being formed at the same time, according to the equation $6\text{FeCl}_2 + 6\text{HCl} + 2\text{HNO}_3 = 3\text{Fe}_2\text{Cl}_6 + 2\text{NO} + 4\text{H}_2\text{O}$. The liquid should now be tested for ferrous salt by placing a drop upon a porcelain plate and adding a drop of freshly-dissolved potassium ferrieyanide. If a blue color or precipitate is pro-

duced a little more nitric acid is required. Should the brown color be merely darkened, the iron has been all oxidized; but there may be an excess of nitric acid, which is detected by placing a drop of the liquid upon a plate in contact with a little ferrous sulphate and adding a drop of strong sulphuric acid. The production of a black color indicates the presence of free nitric acid, which cannot be completely removed by boiling, but requires the addition of a little hydrochloric acid and the application of heat to expel the nitric oxide and chlorine formed, until no more nitric acid is shown by the test. During this and the subsequent operation the use of iron spatulas or stirrers must be carefully avoided; only porcelain or glass should be used.

On evaporating a solution of ferric chloride to the crystallizing point, vapors containing hydrochloric acid are given off as soon as the temperature reaches a certain point, which varies with the strength of the solution; and if the heat is raised to the boiling-point ferric chloride is mechanically carried off. Should evaporation become necessary, it should be done at a gentle heat, and it will be found of advantage to have a slight excess of hydrochloric acid at the beginning of the evaporation. If this acid has been of the official strength, about 63 parts (7 oz. av.) of crystallized ferric chloride will be finally obtained. The crystallization may be effected by keeping the capsule in a warm place until the contents solidify, but the crystals will then be very damp from enclosed moisture. It is far better to follow the directions of the Pharmacopœia, and have the liquid of less weight than the expected salt; on cooling, the mass will now remain liquid, and is set aside loosely covered to protect it from dust and other impurities, and at the same time to admit the atmosphere, from which it will attract moisture and gradually crystallize. The crystals begin to form as small circular nodules having a radiated appearance, floating upon the liquid, and increasing in size until the entire liquid forms a solid mass, which adheres firmly to the vessel. By warming it slightly the mass is readily detached, and should be at once broken into pieces, and put into dry, well-stopped bottles.

Properties.—The official ferric chloride forms orange-colored wart-like pieces which have a crystalline texture and a slight odor of hydrochloric acid, are very deliquescent, forming a thick red-brown liquid having a density of about 1.55, and formerly known as *Oleum martis per deliquium*. The salt is readily and completely soluble in water, alcohol, and ether, yielding yellowish-brown solutions of an acid reaction and a strongly styptic ferruginous taste. The crystals fuse, according to Ordway, at 35.5° C. (96° F.); at a higher temperature they are partly decomposed and volatilized. The aqueous solution shows the reactions of ferric salts and chlorides in yielding a red-brown precipitate with ammonia-water or other alkalies, a blue one with potassium ferrocyanide, and a white one, insoluble in nitric acid, with silver nitrate.

Tests.—The complete solubility in the solvents mentioned is generally an indication of the absence of other metallic salts. The presence of nitric acid or of ferrous salt is detected as described above. A few drops of an aqueous solution of the salt, to which a small crystal of ferrous sulphate has been added, should, on the addition of a drop of strong sulphuric acid, not show a black or brown-black color, and a few drops of a similar solution should, on the addition of a drop of freshly-prepared solution of potassium ferrocyanide, produce an olive-brown color, without a trace of blue. A solution of the chloride in water should not be precipitated by barium chloride (absence of sulphate), and when precipitated by an excess of ammonia the filtrate, on evaporation to dryness, should leave only ammonium chloride, which is completely volatilized at a red heat (absence of alkalies, alkaline earths, zinc, etc.). Copper, if present, is detected by the black precipitate formed in the ammoniacal filtrate with sulphuretted hydrogen, and zinc by the white precipitate formed under the same condition. A 1 per cent. solution of the salt in distilled water when heated to boiling in a test-tube should remain clear (absence of oxychloride); the hot liquid is of a dark red-brown color, and is precipitated by sodium chloride, the precipitate being soluble again in pure water, but on continuing the heat the liquid becomes permanently turbid (Krecke, *Jour. Prak. Chem.*, 1871. iii. p. 286).

Allied Salt.—*FERRUM CHLORATUM*, *P. G.* 1872; *Ferrum muriaticum oxydulatum*, *Chloridum ferrosus*.—Ferrous chloride, *E.*: Protochlorure de fer, *Fr.*; Eisenchlorür, *G.* Formula $\text{FeCl}_2 \cdot 2\text{H}_2\text{O}$. Molecular weight 162.7—520 parts of hydrochloric acid are allowed to act upon 110 parts of iron wire, finally with the application of heat, until hydrogen gas ceases to be given off, when the solution is rapidly filtered. If now 1 part of hydrochloric acid and sufficient distilled water to make the whole weigh 1000 parts are added, *Liquor ferri chlorati* (*s. muriatici oxydulati*) is obtained. The salt is prepared by evaporating the solution immediately after filtration, and very rapidly, until a pellicle is formed, when 1 part of hydrochloric acid is added, and the evaporation continued with stirring until the mass becomes rather stiff: the capsule is now

removed from the fire, and the salt, after it has solidified, is powdered. It is a greenish-white powder, and dissolves in its own weight of water, affording a green solution, which, on being mixed with three times its measure of alcohol, yields no precipitate (absence of ferrous sulphate, etc.). Since ferrous chloride is very easily oxidized on exposure to air, Hager recommended to deoxidize the recently-prepared and powdered salt by exposing it in a thin layer for several hours to the direct sunlight. It contains 34.3 per cent. of iron, 43.6 of chlorine, and 22.1 of water of crystallization. Its concentrated aqueous solution yields crystals containing $4\text{H}_2\text{O}$ = 36.2 per cent., which are deliquescent in moist air and on exposure rapidly turn yellowish-green.

Medical Action and Uses.—Chloride of iron is a powerful astringent and hæmæstatic. It is chiefly used topically for stanching hæmorrhage, as in epistaxis, in hæmoptysis (by inhaling an atomized solution), in bleeding from leech-bites, from the jaw after the extraction of teeth, from the tonsils, from ulcers of the neck of the uterus, from the umbilical cord, from the uterus during and subsequent to abortion, from fungous tumors of various parts, etc. It is reported to have acted favorably as a caustic upon *lupoid* or *scrofulous* ulcers when dissolved in 2 parts of water, and upon various chronic *diseases of the skin* when applied in an ointment (1:20). St. Germain claims to have cured vascular *nævi* by injecting them once a week with a single drop of a solution made with 5 parts of "perchloride of iron," 3 parts of chloride of sodium, and 12 parts of distilled water (*Practitioner*, xxvi. 361). Chloride of iron, if kept in a bottle, gradually deliquesces, and may then be applied with a glass rod or brush. As a hæmæstatic, 5 parts of the chloride may be dissolved in 100 parts of distilled water and applied on lint.

(A more detailed account of the action and uses of this preparation will be found in the article on SOLUTION OF CHLORIDE OF IRON.)

Ferrous chloride, it is stated by German authorities, may be given internally in doses of from 1 to 4 grains (Gm. 0.06–0.20).

FERRI CITRAS, U. S.—CITRATE OF IRON.

Ferrum citricum, Citras ferricus.—*Ferric citrate*, E.; *Citrate de sesquioxyde de fer, Citrate ferrique*, Fr.; *Citronensaures Eisenoxyd, Ferricitrat*, G.

Formula $\text{Fe}_2\text{C}_6\text{H}_5\text{O}_7 \cdot 6\text{H}_2\text{O}$. Molecular weight 597.8.

Preparation.—Solution of Citrate of Iron a convenient quantity. Evaporate the solution at a temperature not exceeding 60°C . (140°F .) to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.—U. S.

At a higher temperature than indicated by the formula the salt is slowly reduced to ferrous compound. When the solution is concentrated to a thick, syrupy liquid it is spread on plates, and then dried in a dry or warm place. Failure in sealing is usually due to the incomplete saturation of the citric acid with ferric hydrate, occasionally to the presence of saline impurities retained by the negligently washed hydrate. The yield is near 44 per cent.

Properties.—If of the proper composition, the salt readily comes off the plates in the form of thin, transparent, garnet-red scales which yield a red-brown powder, are permanent in the air, inodorous, and have a faint ferruginous taste and an acid reaction. It is insoluble in alcohol, and dissolves completely but slowly in cold water, and easily in boiling water. Its solution is darkened, but not precipitated, by ammonia. When strongly heated the salt is decomposed, emitting fumes having the odor of burnt sugar and leaving an ash consisting of ferric oxide, weighing 26.73 (26. U. S.) per cent. Wittstein obtained from the dry salt, by ignition, 29.5 to 30 per cent. of oxide of iron; and this result agrees with the statement of Rother (1883), that the scales lose only 10 per cent. of water; this would make the formula $\text{Fe}_2(\text{C}_6\text{H}_5\text{O}_7)_2 \cdot 3\text{H}_2\text{O}$ and the molecular weight 543.8. On being boiled with an excess of potassa solution the salt or its solution yields a precipitate of ferric hydrate, and the filtrate, on being neutralized with acetic acid and then boiled with test solution of calcium chloride, gives a white granular precipitate of calcium citrate.

Tests.—Ferric citrate is not liable to adulteration. The presence of tartaric acid would be detected by acidulating the solution with a few drops of hydrochloric acid, and then adding some potassium acetate, when cream of tartar would be precipitated. The ash obtained by incinerating the salt should not have an alkaline reaction (absence of fixed alkalis).

Ammonio-citrate of iron is sometimes sold as *soluble citrate of iron*; it resembles the former in appearance and behavior, except that it has a neutral reaction, is more readily

soluble in cold water, gives off the odor of ammonia when heated with an excess of potassa solution, and does not strike a blue color on mixing its solution with potassium ferrocyanide unless it be acidulated with hydrochloric acid.

Medical Uses.—This is a mild preparation, and suitable for children and persons of a delicate stomach. It should be given in a watery solution, and in the *dose* of from 5 to 20 grains (Gm. 0.30–1.20).

FERRI ET AMMONII CITRAS, U. S.—CITRATE OF IRON AND AMMONIUM.

Ferri et ammoniæ citras, Br.; *Ferrum citricum ammoniatum*, *Ferri ammonio-citras*, *Ferro-ammonium citricum*.—*Ammonio-ferric citrate*, *Ammonio-citrate of iron*, *Soluble citrate of iron*, E.; *Citrate de fer et d'ammoniaque (de fer ammoniacal)*, *Citrate ferrique ammoniacal*, Fr.; *Ferriammonicitrat*, *Citronensaures Eisenoxyd-Ammonium* (*Ammoniak*), G.

Preparation.—Take of Solution of Citrate of Iron 3 parts (21 oz. av. or a pint); Water of Ammonia 1 part (7 oz. av. or 7 fluidounces). Mix the solution of citrate of iron with the water of ammonia, evaporate the mixture, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—U. S.

Take of solution of persulphate of iron 8 fluidounces; solution of ammonia 19½ fluidounces; citric acid 4 ounces; distilled water a sufficiency. Mix 14 fluidounces of the solution of ammonia with 2 pints of distilled water, and to this add gradually the solution of persulphate of iron, previously diluted with 2 pints of distilled water, stirring them constantly and briskly. Let the mixture stand for 2 hours, stirring it occasionally; then put it on a calico filter, and when the liquid has drained away wash the precipitate with distilled water until that which passes through the filter ceases to give a precipitate with chloride of barium. Dissolve the citric acid in 8 ounces of distilled water, and, having applied the heat of a water-bath, add the oxide of iron, previously well drained, and stir them together until the whole or nearly the whole of the oxide has dissolved. Let the solution cool: then add 5½ fluidounces of solution of ammonia. Filter through flannel, evaporate to the consistence of syrup, and dry it in thin layers on flat porcelain or glass plates at a temperature not exceeding 100° F. Remove the dry salt in flakes, and keep it in a stoppered bottle.—Br.

The second formula requires the preparation of hydrate of iron by decomposing ferric sulphate with ammonia. It is washed, and then dissolved in citric acid to obtain a solution of ferric citrate, which, without being filtered, is mixed with ammonia. The turbid liquid at once becomes deeper-colored, and is filtered and concentrated. The United States Pharmacopœia, recognizing a solution of ferric citrate, simply requires it to be mixed with ammonia and concentrated.

Properties.—The salt closely resembles citrate of iron in appearance and behavior, except as stated above. Impurities, if present, may be determined in the same manner. On ignition the salt yields 25 per cent. U. S., not less than 27 per cent. Br., of ferric oxide. Being made from normal ferric citrate with the addition of ammonia, it is probably a mixture or compound of ammonio-ferric citrate with ferric oxy-citrate.

Off. Prep.—*Ferri et strychninæ citras*, *Liq. ferri et quiniæ citratis*, U. S.; *Vinum ferri citratis*, U. S., Br.

Medical Uses.—The advantages of an iron salt containing ammonia are more than contestable upon theoretical grounds, and there is no clinical evidence of its special value. The addition to a solution of the salt of a solution of citric acid causes effervescence. The *dose* is 5 or more grains (Gm. 0.30).

FERRI ET AMMONII SULPHAS, U. S.—SULPHATE OF IRON AND AMMONIUM.

Ferrum sulfuricum oxydatum ammoniatum, *Ferrum ammonio-sulphuricum*, *Ferri ammonio-sulphas*, *Sulphas ammonico-ferricus*, *Alumen ammoniacale ferricum*.—*Ammonio-ferric sulphate*, *Ammonio-ferric alum*, E.; *Sulfate de fer et d'ammoniaque*, *Sulfate ferrique ammoniacal*, *Alun de fer ammoniacal*, Fr.; *Ferriammonsulfat*, *Schwefelsaures Eisenoxyd-Ammonium*, *Ammoniakalischer Eisentalun*, G.

Formula $(\text{NH}_4)_2\text{Fe}_2(\text{SO}_4)_4 \cdot 24\text{H}_2\text{O}$. Molecular weight 963.8.

Preparation.—Take of Solution of Tersulphate of Iron 2 pints; Sulphate of Ammo-

nium $4\frac{1}{2}$ troyounces. Heat the solution of tersulphate of iron to the boiling-point, add the sulphate of ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air.—*U. S.* 1870.

On dissolving the ammonium sulphate in the liquid with the aid of heat a double salt is formed which crystallizes on cooling; the mother-liquor will yield another crop of crystals on being concentrated to about one-half. If the solution of ferric sulphate happens to be slightly deficient in acid, the crystals may be of an unsightly appearance; they should then be redissolved in the mother-liquor by heat and a small quantity of sulphuric acid added before crystallizing.

Properties.—This salt crystallizes like alum in regular octahedrons, which are transparent and colorless or of a pale amethyst or violet color, particularly if crystallized from a solution containing a little free acid. They have the spec. grav. 1.712, are inodorous, of an acid and strongly astringent taste, and efflorescent on exposure to air. The salt suffers decomposition when continually heated in the water-bath or kept in the melted state, even in closed vessels. On the application of heat it melts, parts with its water of crystallization, and is further decomposed, leaving ultimately a light-brown or red-brown residue. The salt is insoluble in alcohol and ether; at 15° C. (59° F.) it requires 3 parts, and at the boiling temperature 0.8 part, of water for solution. The aqueous solution has an acid reaction and is of a brown-yellow color, which gradually changes to red, a basic salt being afterward deposited, and the decomposition being hastened by continued boiling of the solution. This shows the chemical reactions of ferric salts, sulphuric acid, and ammonia, yielding a blue precipitate with potassium ferrocyanide, a white one insoluble in hydrochloric acid with barium chloride, and a red-brown one with potassa solution, an excess of which on heating causing the evolution of vapors of ammonia.

Tests.—If the solution be boiled with an excess of potassa solution, and the colorless alkaline filtrate heated with excess of ammonium chloride, or neutralized with hydrochloric acid and again rendered alkaline by ammonia, it should not yield a white gelatinous precipitate of aluminium hydrate.

Medical Action and Uses.—Like most of the compounds of sulphuric acid with metals, this one is astringent, but its astringency appears to be modified by the ammonia in its composition. It may be advantageously used in chronic *mucous fluxes* of the bowels, vagina, and bronchia when these affections are prolonged by general feebleness and a relaxation of the tissues. *Dose*, from 5 to 15 grains (Gm. 0.30–1.0).

FERRI ET AMMONII TARTRAS, *U. S.*—TARTRATE OF IRON AND AMMONIUM.

Ferri ammonio-tartras, Ferrum tartaricum ammoniatum.—*Ammonio-ferric tartrate, Ammonio-tartrate of iron, E.*; *Tartrate de fer et d'ammoniaque, Tartrate ferrique ammoniacal, Fr.*; *Ferriammoniotartrat, Weinsaures Eisenoxyd-Ammonium, G.*

Formula $2(\text{FeO})\text{NH}_4\text{C}_4\text{H}_4\text{O}_6 \cdot 5\text{H}_2\text{O}$. Molecular weight 565.8.

Preparation.—Solution of Tersulphate of Iron 90 parts (18 oz. av. or $13\frac{3}{4}$ fluidounces); Tartaric Acid 60 parts (12 oz. av.); Water of Ammonia 72 parts ($14\frac{1}{2}$ oz. av. or $14\frac{1}{2}$ fluidounces); Carbonate of Ammonium, Distilled Water, Water, each a sufficient quantity. To the water of ammonia, previously diluted with 180 parts (36 oz. av. or $34\frac{1}{2}$ fluidounces) of cold water, add, constantly stirring, the solution of tersulphate of iron, previously diluted with 900 parts (180 oz. av. or 10 $\frac{1}{2}$ pints) of cold water. Pour the whole on a wet muslin strainer, allow the precipitate to drain, then return it to the vessel, and mix it intimately with 1000 parts (200 oz. av. or 12 pints) of cold water. Again drain it on the strainer, and repeat the operation once or oftener until the washings cause but a slight cloudiness with test solution of chloride of barium. Then allow the precipitate to drain completely. Dissolve one-half of the tartaric acid in 130 parts (26 oz. av. or 25 fluidounces) of distilled water, neutralize the solution exactly with carbonate of ammonium, then add the other half of the tartaric acid, and dissolve by the application of a gentle heat. Then, whilst continuing the heat, which should not exceed 60° C. (140° F.), add the magma of hydrated oxide of iron in small portions at a time until it is no longer dissolved. Filter the solution, evaporate it, at the before-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—*U. S.*

This formula is essentially that suggested by Prof. Procter (1841). By neutralizing one-half of the tartaric acid with ammonium carbonate, ammonium tartrate is formed, which is converted into the acid salt by the addition of the reserved tartaric acid. On digesting this with ferric hydrate a solution is obtained, which, by careful evaporation and drying upon plates, yields the officinal salt in scales.

Properties.—It is in transparent, garnet-red, inodorous scales of a sweetish and slightly ferruginous taste, and yields a rust-colored powder. The Pharmacopœia permits the salt if of a yellowish-brown color. In dry air it is permanent; in a moist atmosphere it is hygroscopic, but scarcely deliquescent. When heated it gives off water and ammonia, is then charred, with the odor of burning sugar, and finally leaves 27.9 per cent. (25 per cent. *U. S.*) of ferric oxide, which amount corresponds with the formula given above. It is very probable, however, that compounds of somewhat different composition may be formed by the officinal process. The salt is not soluble in alcohol or ether, but dissolves slowly and freely in glycerin and water. The latter solution is neutral to test-paper, is darkened but not precipitated by ammonia or by cold solutions of fixed alkalies or their carbonates, and is not colored blue by potassium ferrocyanide unless acidulated. When acidulated with hydrochloric acid and mixed with potassium acetate, potassium bitartrate is precipitated. When heated with potassa solution in excess, a red-brown precipitate of ferric hydrate is deposited, ammonia is given off, and the colorless filtrate, when cooled and strongly acidulated with acetic acid, yields a white crystalline precipitate of potassium bitartrate.

Tests.—The ash obtained on incineration should not have an alkaline reaction; this test readily distinguishes this salt from the next.

Medical Uses.—The only advantage of this salt is the one it shares with the other ammonium salts—viz. that of great solubility. In proportion to its bulk, like them also, it contains but little iron. Its *dose* is from 10 to 30 grains (*Gm.* 0.60–2.0).

FERRI ET POTASSII TARTRAS, *U. S.*—TARTRATE OF IRON AND POTASSIUM.

Ferrum tartaratum, Br.; *Ferri potassio-tartras*, *Ferri-kali tartaricum*, *Ferrum tartarizatum*, *Tartras ferri-potassicus*, s. *potassico-ferricus*, s. *ferrico-kalicus*.—*Potassio-ferric tartrate*, *Tartarated (tartarized) iron*, *Ferro-tartrate of potassium*, E.; *Tartrate de fer et de potasse*, *Tartrate ferri-potassique*, *Tartre chalybé*, *Tartre martial*, Fr.; *Ferrikalitartrat*, *Weinsaures Eisenoxyd-Kali*, *Eiseneisenstein*, G.

Preparation.—Solution of Tersulphate of Iron 12 parts (18 oz. av. or 13½ fluidounces); Bitartrate of Potassium 4 parts (6 oz. av.); Distilled Water 32 parts (48 oz. av. or 46 fluidounces); Water of Ammonia, Water, each a sufficient quantity. To 10 parts (15 oz.) of water of ammonia, diluted with 20 parts (30 oz. av. or 28½ fluidounces) of cold water, add, constantly stirring, the solution of tersulphate of iron, previously diluted with 100 parts (150 oz. av. or 9 pints) of cold water. Pour the whole on a wet muslin strainer, allow the precipitate to drain, then return it to the vessel and mix intimately with 120 parts (180 oz. av. or 10½ pints) of cold water. Again drain on the strainer, and repeat the operation once or oftener until the washings produce but a slight cloudiness with test solution of chloride of barium. Put the drained precipitate into a stone or porcelain vessel, add to it 32 parts (48 oz. av. or 46 fluidounces) of distilled water, heat the mixture on a water-bath to a temperature not exceeding 60° C. (140° F.), add the bitartrate of potassium, and stir until the hydrated oxide of iron is dissolved. Filter while hot, and let the filtrate stand in a cool, dark place for 24 hours; then stir it well with a porcelain or glass spatula, so that the precipitate which has formed in it may be thoroughly incorporated with the liquid. Now add, very cautiously, just enough water of ammonia to dissolve the precipitate, evaporate the solution in a porcelain vessel to the consistence of thick syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—*U. S.*

The formula of the British Pharmacopœia is like the above, the proportions used being solution of persulphate of iron 5½ fluidounces, solution of ammonia 10 fluidounces, and acid tartrate of potassium 2 ounces. As in the preceding case, ferric hydrate is first formed, and this is used for saturating the potassium salt. A salt of the formula $K_6Fe_26C_4H_4O_6$ is probably first formed, which would yield somewhat over 12 per cent. (Dulk found 12.78 per cent.) of ferric oxide; the British Pharmacopœia requires 15; Soubeiran and Capitaine obtained 30.8 per cent. of ferric oxide, and regarded the salt as

having the composition $K(FeO)(C_4H_4O_6)$. It is likely that different basic compounds may be formed by prolonged digestion. To render the salt perfectly and readily soluble in water, the U. S. P. now directs the addition of a little ammonia-water to the filtered solution before evaporation—a course recommended for this and analogous salts by Mr. G. H. C. Klie in 1876.

Properties.—In its physical properties, as well as in its behavior to solvents, alkalies, and potassium ferrocyanide, it resembles tartrate of iron and ammonium, from which it differs in giving off a slight odor of ammonia when heated with potassa solution, and, when incinerated, in leaving an ash which has an alkaline reaction to test-paper and effervesces on the addition of hydrochloric acid.

TARTARUS FERRATUS, *s. Tartarus martiatus*, is made by digesting 1 part of iron filings and 5 parts of commercial cream of tartar with water until a small portion of it is found to be almost wholly soluble in water when it is dried and powdered. It is a dirty-greenish powder, gradually turning brown, and is almost wholly soluble in 16 parts of cold water. It consists chiefly of potassio-ferrous tartrate, but is rarely used now, having been superseded by the potassio-ferric salt.

GLOBULI MARTIS, *s. Glob. tartari ferruginosi*.—Iron balls, Steel balls, *E.*; Boules de Mars, B. de Nancy, *Fr.*; Stahlkugeln, *G.*—As made by the French Codex, they are an impure tartrate of iron and potassium, made by digesting iron filings and crude tartar in a strained decoction of *vulnery species* (consisting of twenty different herbs and flowers), and after evaporation, with the aid of a little gum-arabic, forming the mass into balls weighing about 30 Gm. (1 oz.). Other formulas omit the herbs.

Medical Uses.—This salt is one of the richest in iron, the most agreeable to the taste, the least irritating to the bowels and oppressive to the stomach, and the least apt to occasion constipation, of all the soluble ferruginous preparations. *Dose*, from 5 to 20 grains (Gm. 0.30–1.20) three times a day, before meals.

Tartarus ferratus, as above stated, is made into balls which in France are known as *boules de Mars* and *boules de Nancy*, and, dissolved in hot water, are added to baths as a substitute for natural chalybeate waters. It is also given internally in carbonated water, sherry wine, or syrup.

FERRI ET QUININÆ CITRAS, U. S.—CITRATE OF IRON AND QUININE.

Ferri et quiniæ citras, Br., U. S. 1870; *Chininum ferro-citricum*, P. G.; *Citras ferrico-quinicus*.—*Citrate de fer et de quinine*, Fr.; *Ferrichinincitrat*, *Citronsäures Eisen-Chinin*, G.

Preparation.—Citrate of Iron 88 parts ($5\frac{1}{2}$ oz. av.); Quinine, dried at 100° C. (212° F.) until it ceases to lose weight, 12 parts ($\frac{3}{4}$ oz. av.); Distilled Water a sufficient quantity; to make 100 parts ($6\frac{1}{2}$ oz. av.). Dissolve the citrate of iron in 160 parts (10 oz. av. or 9½ fluidounces) of distilled water by heating on a water-bath, at a temperature not exceeding 60° C. (140° F.). To this solution add the quinine, and stir constantly until it is dissolved. Lastly, evaporate this solution, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—*U. S.*

Take of solution of persulphate of iron 4½ fluidounces; sulphate of quinia 1 ounce; diluted sulphuric acid 12 fluidrachms; citric acid 3 ounces; solution of ammonia, distilled water, each a sufficiency. Mix 8 fluidounces of the solution of ammonia with 2 pints of distilled water, and to this add the solution of persulphate of iron, previously diluted with 2 pints of distilled water, stirring them constantly and briskly. Let the mixture stand for 2 hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away wash the precipitate with distilled water until that which passes through the filter ceases to give a precipitate with chloride of barium. Mix the sulphate of quinia with 8 ounces of distilled water, add the diluted sulphuric acid, and when the salt is dissolved precipitate the quinia with a slight excess of solution of ammonia. Collect the precipitate on a filter and wash it with 1½ pints of distilled water. Dissolve the citric acid in 5 ounces of distilled water, and, having applied the heat of a water-bath, add the oxide of iron previously well drained; stir them together, and when the oxide has dissolved add the precipitated quinia, continuing the agitation until this also has dissolved. Let the solution cool, then add, in small quantities at a time, 12 fluidrachms of solution of ammonia diluted with 2 fluidounces of distilled water, stirring the solution briskly, and allowing the quinia, which separates with each addition of ammonia, to dissolve before the next addition is made. Filter the solution, evaporate it

to the consistence of a thin syrup, and then dry it in thin layers on flat porcelain or glass plates at a temperature of 100° F. Remove the dry salt in flakes and keep it in a stoppered bottle.—*Br.*

The process of the U. S. Pharmacopœia consists simply in dissolving quinine in solution of ferric citrate. The apparently complicated process of the British Pharmacopœia in its first part directs the preparation of ferric hydrate and quinine, which are successively dissolved in citric acid; but it differs very materially in the subsequent addition of ammonia and in the formation of ammonium citrate, by which the physical properties of the resulting scales are changed.

The corresponding salt of the German Pharmacopœia again differs in containing, besides quinine, both ferric and ferrous salt, but no ammonia; it is made by digesting powdered iron 3 parts with citric acid 6 parts and water 500 parts, adding afterward quinine 1 part, freshly precipitated by soda solution from 1.3 parts of quinine sulphate; the solution is then evaporated and scaled.

Properties.—The product of the first process is in transparent, inodorous scales of a yellowish green-brown to reddish-brown color, varying according to their thickness. When heated to near redness, like other citrates it emits fumes having the odor of burnt sugar, and it finally leaves a brown ash free from alkaline reaction to test-paper. The salt is permanent in the air, or, according to the U. S. P., slowly deliquescent on exposure; it dissolves slowly in cold, more readily in hot, water, is slightly soluble in alcohol, and insoluble in ether. The solution is slightly acid to test-paper, has a bitter and mildly chalybeate taste, and yields with tannin a grayish-black precipitate consisting of the mixed tannates of iron and quinine. On the addition of ammonia the liquid darkens in color, yields a white curdy precipitate of quinine, and the filtrate gives a blue precipitate with potassium ferrocyanide after the addition of hydrochloric acid. The solution of the salt on being heated with excess of potassa solution gives a precipitate of ferric hydrate and quinine, without evolving vapors of ammonia, and the filtrate after the addition of calcium chloride, again filtering, and then boiling, yields a white granular precipitate of calcium citrate.

The product of the British Pharmacopœia corresponds with the behavior and tests described above, except that it is readily soluble in cold water; it is of a greenish golden-yellow color and in the air somewhat deliquescent.

Tests.—"Dissolve 4 Gm. of the scales in 30 Cem. of water in a capsule with the aid of heat. Cool, and transfer the solution to a glass separator, rinsing the capsule; add an aqueous solution of 0.5 Gm. of tartaric acid, and then solution of soda in decided excess. Extract the alkaloid by agitating the mixture with four successive portions of chloroform, each of 15 Cem. Separate the chloroformic layers, mix them, evaporate them in a weighed capsule on the water-bath, and dry the residue at a temperature of 100° C. (212° F.). It should weigh 0.48 Gm."—*U. S.* "50 grains dissolved in a fluidounce of water and treated with a slight excess of ammonia give a white precipitate which, when collected on a filter and dried, weighs 8 grains; the precipitate is almost entirely soluble in ether, and when burned leaves but a minute residue."—*Br.* "If the solution of 1 Gm. of the salt in 4 Cem. of water be precipitated with soda solution, and then agitated with 10 parts of ether, the ethereal liquid on being evaporated should leave behind at least 0.09 Gm. of quinine."—*P. G.* The salt contains 16 per cent. *Br.*, 12 per cent. *U. S.*, 10 per cent. *P. G.*, of quinine. It might be added that its solution in dilute sulphuric acid shows the characteristic behavior of quinine solutions. (See QUININÆ SULPHAS.)

Medical Uses.—This preparation has no demonstrable advantage over an extemporaneous union of its components except from the convenience of dispensing it. 5 parts of it contain about 1 part of quinia, and it may be prescribed in pill or solution, before meals, in the *dose* of about 5 grains (Gm. 0.30).

FERRI ET STRYCHNINÆ CITRAS, U. S.—CITRATE OF IRON AND STRYCHNINE.

Ferri et strychninæ citras. U. S. 1870.—*Citrate de fer et de strychnine.* Fr.: *Citronensäures Eisen-Strychnin*, G.

Preparation.—Citrate of Iron and Ammonium 98 parts (490 grains); Strychnine 1 part (5 grains); Citric Acid 1 part (5 grains); Distilled Water 120 parts (600 grains or 10½ fluidrachms); to make 100 parts (500 grains). Dissolve the citrate of iron and ammonium in 100 parts of distilled water, and the strychnine, together with the citric

acid, in 20 parts of distilled water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60°C . (140°F .), to the consistency of syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—*U. S.*

This is simply a mixture of citrate of strychnine with ammonio-ferric citrate, sealed in precisely the same manner as the other iron preparations.

Properties.—It closely resembles ammonio-citrate of iron in appearance, and has the same behavior to reagents as described above, but differs from it in the distinctly bitter taste and in the white precipitate produced by ammonia, the precipitate being soluble in boiling alcohol, from which, if the solution is sufficiently concentrated, crystals will be obtained giving the peculiar reactions of strychnine. The alkaloid will also be obtained by adding potassa solution to the solution of the salt, agitating with chloroform, and evaporating the chloroform solution.

Test.—If 1 Gm. of the salt be dissolved in 4 Cem. of distilled water, and this liquid mixed with 1 Cem. of potassa solution, and the mixture be well agitated with fresh portions of chloroform until exhausted, the mixed chloroform solutions on being evaporated should leave a residue weighing between 0.009 and 0.01 Gm.

Medical Uses.—This very unnecessary official compound may be prescribed in doses of 1 or 2 grains (Gm. 0.05–0.10) and cautiously increased.

FERRI FERROCYANIDUM.—FERROCYANIDE OF IRON.

Ferri ferrocyanuretum, Ferrum ferrocyanatum (s. borussicum, s. zooticum), Ferrocyanidum ferricum, Cyanuretum ferroso-ferricum, Cæruleum borussicum.—*Ferrocyanuret of iron, Prussian blue, Williamson's blue, Paris blue, E.; Ferrocyanure (Prussiate, Cyanure) de fer, Bleu de Prusse (de Berlin), Fr.; Ferrocyaneisen, Berliner Blau, G.*

Formula, $\text{Fe}_4(\text{FeCy}_6)_3 = \text{Fe}_4\text{Fe}_3(\text{CN})_6$. Molecular weight 859.3.

Preparation.—Take of Ferrocyanide of Potassium 9 troyounces; Solution of Tersulphate of Iron a pint; Water 3 pints. Dissolve the ferrocyanide of potassium in 2 pints of the water, and add the solution gradually to the solution of tersulphate of iron previously diluted with the remainder of the water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it and rub it into powder.—*U. S.* 1870.

The process is one of simple decomposition, the basylous radicals exchanging their acids; thus, $3\text{K}_4\text{FeCy}_6 + 2\text{Fe}_2(\text{SO}_4)_3 = 6\text{K}_2\text{SO}_4 + \text{Fe}_4(\text{FeCy}_6)_3$. The precipitate requires considerable washing to free it from the potassium salt, and when dried at a temperature of about 40°C . (104°F .) or less it retains $18\text{H}_2\text{O}$ in combination, which it gradually loses at a higher temperature.

For uses in the arts Prussian blue is made by precipitating ferrous sulphate with potassium ferrocyanide, and exposing the bluish-white precipitate to the air or treating it with oxidizing agents until it has acquired the proper shade; the commoner varieties contain alumina and other impurities. The pigment was accidentally discovered by Diesbach, a manufacturer of colors in Berlin, and a notice of the discovery published in 1710; but processes for preparing it were first published by Woodward, John Brown, and Stephane F. Geoffroy (1724–25); most of the noted chemists of the past and of the early part of the present century were engaged in the investigation of its composition and of that of allied compounds.

Properties.—Ferric ferrocyanide is in hard dark-blue masses which exhibit upon the fresh somewhat conchoidal fracture a reddish metallic lustre and yield a deep-blue powder. It is inodorous, tasteless, insoluble in water, alcohol, and dilute mineral acids, but dissolves while moist in solution of ammonium nitrate with a violet-blue color, and yields with oxalic acid, equal to one-sixth or upward of its own weight, a powder which dissolves completely in water, and which has been used as *wash-blue* and *blue ink*; the residue left on evaporating the solution to dryness has been known as *Bleu Suisse* or *Swiss blue*. Commercial Prussian blue should be previously purified for this purpose by treating it with dilute hydrochloric or sulphuric acid and washing it with water. Concentrated mineral acids decompose it, with the liberation of hydrocyanic acid; when boiled with alkalis ferric hydrate is separated and alkaline ferrocyanide dissolved; and when heated in contact with air ammoniacal vapors are given off and a rust-colored residue is left containing ferric oxide and potassium cyanate, the latter resulting from potas-

sium compounds present in the pigment. Prussian blue is hygroscopic, and contains about 28 per cent. of water.

Impurities and Adulterations.—On boiling impure Prussian blue with dilute hydrochloric acid, the presence of carbonates will be indicated by effervescence, and the potassium sulphate, alumina, and ferric hydrate will enter into solution. Ammonia-water added to the solution will precipitate some of these impurities, and the filtrate may be tested for calcium by oxalic acid or evaporated to dryness and ignited, when no residue should be left. The ammonia, if any, is evolved when boiled with potassa solution, which leaves ferric hydrate behind, and, if alumina should have been present, the clear liquid will yield a white precipitate on being neutralized with hydrochloric acid and again rendered alkaline by ammonia. On incinerating Prussian blue and treating the residue with strong hydrochloric acid, barium sulphate (heavy spar) will be left undissolved, and the clear acid filtrate, when diluted with water, will yield a black precipitate with sulphuretted hydrogen should lead or allied metals have been present.

Allied Compounds.—**SOLUBLE PRUSSIAN BLUE.** On adding a solution of a ferric salt (anhydrous ferric chloride 1 part) to a solution of potassium ferrocyanide 3 parts (not the reverse), keeping the latter in excess, the deep blue precipitate will become soluble in water as soon as the greater portion of the foreign salts has been washed out; the precipitate is *potassium ferri-ferrocyanide* $K_3Fe_3'''(Fe''Cy_6)_2$. A similar soluble precipitate is obtained by adding a ferrous salt (ferrous sulphate 11 parts) to a solution of red prussiate of potash (potassium ferricyanide), but it has the composition $K_2F_2'''(Fe'''Cy_{12})$, and is *potassium ferro-ferricyanide*.

TURNBULL'S BLUE, FERRICYANIDUM FERROSUM, $Fe_3(Fe_2Cy_{12})$, was discovered by Gmelin (1827), and is obtained by adding potassium ferricyanide to the solution of a ferrous salt.

Medical Uses.—The daily *dose* of this preparation is stated by certain authorities to be from $\frac{1}{2}$ drachm to 5 drachms (Gm. 2–20). It is probably inert. To this statement, contained in the first edition of the present work, may be added the more recent conclusions of Hayem from a series of careful and minute observations. Ferrocyanide of potassium is valueless as a chalybeate, and has no influence in regenerating the blood. Its iron remains inert, and the elements of the cyanogen exert no poisonous action. It may be taken for weeks or months in the daily dose of several Gm. without in the least affecting the health, and in doses of from 2 to 6 Gm. it neither alters the quantity of the urine nor the elimination of urea. Cases of anæmia which, after a prolonged trial it failed entirely to benefit, were readily and permanently cured by the soluble salts of iron—the chloride, for example.

FERRI HYPOPHOSPHIS, U. S.—HYPOPHOSPHITE OF IRON.

Ferrum hypophosphorosum, Hypophosphis ferricus.—*Ferric hypophosphite*, E.; *Hypophosphite de fer*, Fr.; *Ferrihypophosphit, Unterphosphorigsaures Eisenoxyd*, G.

Formula $Fe_2PH_2O_2$. Molecular weight 501.8.

Preparation.—A solution of hypophosphite of sodium which is free from carbonate is added to a solution of ferric chloride or ferric sulphate, which should not contain any excess of acid. The precipitate is well washed with distilled water and dried with a moderate heat. It is a process of double decomposition between the sodium and ferric salts. The presence of carbonate in the former would contaminate the salt with a corresponding quantity of ferric hydrate, while an excess of acid would occasion loss by preventing the ferric hypophosphite from being precipitated.

Properties.—It is a white or grayish powder, inodorous, nearly tasteless, slightly soluble in water, more so in hypophosphorous acid, but freely so in hydrochloric acid. Like other insoluble or sparingly-soluble ferric salts, it dissolves in solutions of an alkali citrate, with a green color. It is readily oxidized by nitric acid and other oxidizing agents, and when heated in the dry state evolves inflammable hydrogen phosphide and leaves ferric pyrophosphate. Its formula is given above; it contains, in addition, water of hydration, the amount of which has not been determined.

Tests.—It should be completely soluble in dilute acetic acid, which leaves white ferric phosphate undissolved. This solution should not be precipitated by oxalate of ammonium (absence of calcium salt).

Medical Action.—It is theoretically assumed to possess virtues belonging to phosphorus as well as iron—an assumption which nothing justifies. It may be given in *doses* of from 5 to 10 grains (Gm. 0.30–0.60).

FERRI IODIDUM SACCHARATUM, U. S.—SACCHARATED IODIDE OF IRON.

Ferrum iodatum saccharatum.—Saccharated ferrous iodide, E.; *Saccharure d'iodure de fer*, Fr.; *Eisenjodürzucker*, G.

Formula of ferrous iodide FeI_2 . Molecular weight 309.1.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 6 parts (30 grains); Iodine 17 parts (85 grains); Distilled Water 20 parts (100 grains or $1\frac{1}{4}$ fluid-drachms); Sugar of Milk 80 parts (400 grains). Mix the iron, iodine, and distilled water in a flask of thin glass; shake the mixture occasionally until the reaction ceases and the solution has acquired a green color and lost the smell of iodine; then filter it through a wetted filter into a porcelain capsule containing 40 parts of sugar of milk. Rinse the flask and iron wire with a little distilled water, pass the rinsings through the filter into the capsule, and evaporate on a water-bath, constantly stirring, until a dry mass remains. Transfer the mass quickly to a heated iron mortar containing the remainder of the sugar of milk, and reduce the whole to powder. Transfer the powder at once to small, well-dried bottles, which must be securely stopped and kept in a cool and dark place.—U. S.

This is the process of the German Pharmacopœia of 1872, modified only by slightly increasing the iodine, so that the finished preparation may contain fully 20 per cent. of ferrous iodide. Iodine unites with the iron in the presence of water, heat being produced, which may increase to such an extent that some iodine may be volatilized; should violet-colored vapors make their appearance in the flask, the violence of the reaction should be checked by immersing the flask in cold water; toward the end of the process it may, on the other hand, become necessary to hasten the combination of the last portions of iodine by the application of a gentle heat. Instead of bringing the whole of the iodine in contact with the whole amount of iron, as directed in the formula, it is better to add one of these in several portions, waiting after each addition until the reaction has nearly ceased. In warm weather especially it will be preferable, in order to avoid loss by evaporation, to introduce the iodine and water into the flask and to add the iron gradually. The green liquid, being a very concentrated solution of ferrous iodide, should be passed through a small wetted filter, and the flask and filter should be well rinsed twice with a small quantity of distilled water to recover all the iodide. 17 parts of iodine yield $20\frac{1}{4}$ parts of ferrous iodide, and this quantity, mixed with 80 parts of milk-sugar, will give a mixture containing 20.6 per cent. of ferrous iodide if all loss has been avoided.

Properties.—Saccharated ferrous iodide is a yellowish or grayish-white powder, very hygroscopic, odorless, having a sweetish ferruginous taste and a slightly acid reaction. It is soluble in 7 parts of water at 15°C . (59°F .), forming an almost clear and nearly colorless solution, and is only partially soluble in alcohol. When strongly heated the compound swells up, chars, evolves the odor of iodine and of burnt sugar, and on ignition leaves a residue which should yield nothing soluble to water (absence of alkali salts). The aqueous solution yields a light-greenish precipitate with ammonia, and a blue precipitate with test solution of ferricyanide of potassium. If mixed with some gelatinized starch, and afterward with a little chlorine-water, the solution assumes a blue color.

Tests.—The aqueous solution of saccharated ferrous iodide should not be colored blue on the addition of gelatinized starch (absence of free iodine). “On mixing an aqueous solution of 5 Gm. of saccharated iodide of iron with a solution of 1 Gm. of nitrate of silver and filtering, the filtrate should still produce a precipitate or cloudiness with test solution of nitrate of silver (presence of at least 20 per cent of ferrous iodide).”—U. S. This is an error; the test, as stated, indicates more than 18.214 per cent. of ferrous iodide. While it may perhaps be perfectly admissible to regard the percentage stated as the lowest limit, the test was better adapted to the product of the P. G. 1872, which contained only 19.5 per cent. of ferrous iodide.

Allied Preparations.—FERRI IODIDUM, Br.: *Ferrum iodatum*, P. G.: *Ioduretum ferrosium*.—Iodide of iron, Ferrous iodide, E.: *Iodure de fer*, Fr.: *Eisenjodür*, G.—The British and French Pharmacopœias still recognize this unstable salt, which is made by uniting iodine and iron in the proportion given above and in the presence of water, filtering the green solution, and evaporating it rapidly in a dish of polished iron until a drop of the solution taken out on the end of an iron wire solidifies on cooling. The liquid should now be poured out on a porcelain dish, and as soon as it has solidified should be broken into fragments and enclosed in a well-stopped bottle. The solution of ferrous iodide, on evaporation, is readily oxidized: hence the direction to evaporate in a polished iron dish, which, however, cannot prevent the formation of oxide, or possibly oxy-iodide, of iron. The residuary salt is therefore never completely soluble in water. The German Pharmacopœia orders the salt to be prepared extemporaneously by combining iodine 82 parts and

powdered iron 30 parts under distilled water 100 parts: the filtered liquid contains 100 parts of ferrous iodide, and is used in this condition for liquid preparations, or if required in pills the solution is rapidly evaporated in an iron dish.

According to De Luca, pure anhydrous ferrous iodide is white, and in the presence of moisture greenish. The Pharmacopœias require it to be green with a tinge of brown. By the above process, however, it is usually obtained as a steel-gray laminated mass, with a metallic lustre, fusing at about 177° C. (350° F.) and evolving vapors of iodine. It is deliquescent when pure, dissolves readily with a green color in water, also in glycerin and alcohol, the solution yielding a dark-blue precipitate with potassium ferrieyanide, and separating iodine on the addition of a little chlorine-water, when on the further addition of mucilage of starch a blue color will be produced.

Solid ferrous iodide is at best a very unsatisfactory medicinal preparation, owing to the unavoidable changes occurring under ordinary circumstances. It would be better, by far, when ferrous iodide is desired in a solid form, to evaporate a definite quantity of the officinal syrup, and convert that at once into pills by the addition of some vegetable powder. The saccharated ferrous iodide is to a certain extent, though not indefinitely, protected by the sugar.

Medical Action and Uses.—They are sufficiently described under SYRUPUS FERRI IODIDI, which, with *Pilula ferri iodidi*, is the only other officinal preparation (*U. S. P.*) that contains iodine and iron in combination. The *dose* of this iodide may be stated at 5 grains (Gm. 30), three times a day. It should be prescribed in pilular form and taken after meals.

FERRI LACTAS, *U. S.*—LACTATE OF IRON.

Ferrum lacticum, P. G.; *Lactas ferrosus*.—*Ferrous lactate*, E.; *Lactate ferreux*, *Lactate de fer*, Fr.; *Ferrolaktat*, *Eisenlaktat*, *Milchsäures Eisenoxydul*, G.

Formula $\text{Fe}_2\text{C}_3\text{H}_5\text{O}_3 \cdot 3\text{H}_2\text{O}$. Molecular weight 287.9.

Preparation.—A formula for the preparation of this salt was given by the *U. S. P.* 1870: a fluidounce of lactic acid diluted with a pint of distilled water is digested in an iron vessel with $\frac{1}{2}$ ounce of iron filings until the action has ceased, when the hot solution is filtered and crystallized. In this process the iron unites directly with the acid, displacing the basylous hydrogen, the solution of ferrous lactate merely requiring to be evaporated and crystallized. It may also be prepared from crystalline calcium lactate, $\text{Ca}(\text{C}_3\text{H}_5\text{O}_3)_2 \cdot 5\text{H}_2\text{O}$, obtained in the preparation of lactic acid (see page 71) by dissolving 31 parts of it in 750 or 800 parts of water, and mixing this with a solution of 28 parts of crystallized ferrous sulphate; by double decomposition ferrous lactate is formed and remains in solution, while most of the calcium sulphate is precipitated, the remainder being removed by mixing the liquid with one-tenth volume of alcohol; the filtrate is finally evaporated and crystallized. A similar process has been adopted by the French Codex.

Both these processes involve considerable evaporation, which may be avoided, according to Pagenstecher (1842), by mixing an alcoholic solution of sodium lactate (see Boutron and Frémy's process for lactic acid, page 71) with a freshly-prepared solution of ferrous chloride, when nearly the whole of the ferrous lactate will crystallize out, and the alcohol used may be recovered by distilling the mother-liquor. Thus prepared, the salt is less prone to oxidation.

Properties.—Ferrous lactate forms a greenish-white or yellowish crystalline powder or crusts consisting of small needle-shaped crystals containing 19 per cent. of water of crystallization, and having a slight peculiar odor, a sweetish and mild chalybeate taste, and a slightly acid reaction. The dry salt is nearly permanent in dry air, but in a damp atmosphere is gradually converted into ferric salt. It is almost insoluble in cold alcohol, but may be crystallized from boiling diluted alcohol; it dissolves slowly at 10° C. (50° F.) in 48 parts, and at 15° C. (59° F.) in 40 parts, *U. S.*, in 38.2 parts, *P. G.*, of water, and in 12 parts of boiling water, the solutions being of a greenish-yellow color, and it is freely soluble with a green color in solutions of alkali citrates. On the application of heat it turns brown and black, and then, with frothing, emits white acid vapors having the odor of burnt sugar, and finally leaves brownish-red ferric oxide, amounting to 27.7 (about 27 *P. G.*) per cent. The aqueous solution yields a dark-blue precipitate with potassium ferrieyanide, and a light-blue one with potassium ferrocyanide; in contact with the air it turns speedily brown, forming ferric lactate, and then yields at once a dark-blue precipitate with potassium ferrocyanide. The salt, boiled for 15 minutes with an excess of nitric acid diluted with an equal bulk of water, yields on cooling white granules of mucic acid.

Tests.—The salt is not liable to be contaminated with impurities except ferric salt, the formation of which is difficult to prevent by processes requiring much evaporation. Accidental and wilful adulterations are detected by adding to the cold aqueous solution neutral acetate of lead, which should scarcely cause a slight turbidity (absence of more than traces of chlorides, sulphates, citrates, malates, or tartrates). The cold aqueous solution, acidulated with nitric acid, should remain clear or become merely opalescent with silver nitrate (chloride) or barium chloride (sulphate), and if acidulated with hydrochloric acid should with hydrosulphuric acid merely become opalescent from the separation of sulphur by ferric salt, but should not be precipitated or acquire a dark color (absence of heavy metals). A mixture of the salt with strong sulphuric acid should not evolve the odor of butyric acid, nor should it acquire a brown or black color (absence of gum, sugars, and other foreign organic matter). For the detection of cane-sugar the aqueous solution, acidulated with sulphuric acid, should be boiled for 10 to 15 minutes, then rendered alkaline by soda solution, and warmed with test solution of potassio-cupric tartrate, which would then yield a red precipitate of cuprous oxide. The ash obtained by incinerating the salt should not have an alkaline reaction (absence of alkalis).

Off. Prep.—Syrupus hypophosphitum cum ferro, *U. S.*

Medical Action and Uses.—Lactate of iron has been alleged to be more assimilable than other ferruginous salts, upon the ground that lactic acid is a normal secretion of the stomach. Admitting this ground to be settled, the inference is illogical. Clinically, it may be said that lactate of iron is a very unirritating salt, and that owing to its feeble flavor it is taken without repugnance. The statements made of its curative powers are neither more nor less than may be made of other mild salts of iron. It may be given in the *dose* of 1 or more grains (Gm. 0.06) in pill or in solution. Owing to its difficult solution in water and its liability to oxidation, it is not readily dispensed in a liquid form, but it may be dissolved in hot syrup to the extent of about 4 grains to the fluidounce. Attempts have been made to cure *erectile tumors* by injecting them with a solution of "8 grains of lactate of iron to a drachm of distilled water." The statement is incorrect, since the salt requires 48 parts of cold water to dissolve it.

FERRI OXALAS, *U. S.*—OXALATE OF IRON.

Ferrum oxalicum, Oxalus ferrosus.—Ferrous oxalate, *E.*; *Oxalate ferreux, Oxalate de fer, Fr.*; *Ferrooxalat, Oxalsäures Eisenoxydul, G.*

Formula $\text{FeC}_2\text{O}_4 \cdot \text{H}_2\text{O}$. Molecular weight 161.9.

Preparation.—Take of Sulphate of Iron 2 troyounces; Oxalic Acid 436 grains; Distilled Water a sufficient quantity. Dissolve the sulphate of iron in 30 fluidounces, and the oxalic acid in 15 fluidounces, of distilled water. Filter the solutions, and having mixed them with agitation, set aside the mixture until the precipitate is deposited. Decant the clear liquid, wash the precipitate until the washings cease to redden litmus, and dry it with a gentle heat.—*U. S.* 1870.

On adding a solution of oxalic acid to a solution of ferrous salt the acid of the latter is liberated, while the iron unites with the former to ferrous oxalate, which, being almost insoluble, is deposited.

Properties.—It is a pale almost lemon-yellow, inodorous, crystalline powder, requiring 4500 parts of cold and nearly the same quantity of boiling water for solution. Owing to this sparing solubility, the salt is almost tasteless and but little prone to oxidation in the air. It dissolves in cold concentrated hydrochloric and in hot diluted sulphuric acid, but is scarcely soluble in oxalic acid. Alkalies and their carbonates decompose it, with the formation of alkaline oxalates and ferrous hydrate or carbonate; the precipitate, when rapidly collected, washed, and dissolved in diluted hydrochloric acid, yields a dark-blue precipitate with test solution of potassium ferricyanide, while the filtrate from the precipitate, on being supersaturated with acetic acid, gives with calcium chloride a white precipitate of calcium oxalate soluble in hydrochloric acid. When heated to about 155°C . (311°F .) it loses its water of crystallization, and at a higher temperature is completely decomposed, with a faint combustion, yielding in contact with the air 49.3 per cent. of ferric oxide. This corresponds with the formula given above, the correctness of which was proved (1861) by H. Croft and E. Reynold. Formerly it was assumed to contain double the amount of water ($2\text{H}_2\text{O}$).

Medical Uses.—The special therapeutical uses of this preparation are unknown to us. The *dose* is stated to be 2 or 3 grains (Gm. 0.10–0.15).

FERRI OXIDUM HYDRATUM, U. S.—HYDRATED OXIDE OF IRON.

Ferri peroxidum humidum, Br.; *Hydras ferrius*.—Moist peroxide of iron, Ferric hydrate, E.; *Sesquioxyde (Peroxyde) de fer hydraté humide*; *Hydrate de peroxyde de fer gélatineux*, Fr.; *Feuchtes Eisenoxydhydrat*, G.

Formula of freshly-prepared ferric hydrate $\text{Fe}_2(\text{HO})_6$. Molecular weight 213.8.

Preparation.—Solution of Tersulphate of Iron 10 parts (5 oz. av. or $3\frac{1}{2}$ fluidounces); Water of Ammonia 8 parts (4 oz. av. or 4 fluidounces); Water a sufficient quantity. To the water of ammonia, previously diluted with 20 parts (10 oz. av. or $9\frac{1}{2}$ fluidounces) of cold water, add, constantly stirring, the solution of tersulphate of iron previously diluted with 100 parts (50 oz. av. or 3 pints) of cold water. Pour the whole on a wet muslin strainer, and allow the precipitate to drain; then return it to the vessel and mix it intimately with 120 parts (60 oz. av. or $3\frac{1}{2}$ pints) of cold water. Again drain it on the strainer, and repeat the operation. Lastly, mix the precipitate with enough cold water to make the mixture weigh 20 parts (10 oz. av.).

When hydrated oxide of iron is to be made in haste for use as an antidote, the washing may be performed more quickly, though less perfectly, by pressing the strainer forcibly with the hands until no more liquid passes, and then adding enough water to make the whole weigh about 20 parts (10 oz. av.). *Note.*—The ingredients for preparing hydrated oxide of iron as an antidote should always be kept on hand, in a special place, in bottles holding respectively about 10 troyounces or 300 Gm. of solution of tersulphate of iron and about 8 troyounces or 240 Gm. of water of ammonia.—U. S.

Ferric hydrate is prepared from the solution of the sulphate by decomposing the salt with ammonia (U. S. P.), or with soda (Br. P.), the latter authority ordering 4 fluidounces of its solution of persulphate after diluting with a pint (Imp.) of distilled water, to be gradually poured into 33 fluidounces of soda solution, and to set aside for 2 hours before straining and washing the precipitate upon the strainer. In the one case ammonium sulphate, in the other sodium sulphate, is formed—salts which are readily soluble in water and almost completely removed by washing and decantation, as directed above. The brown ferric hydrate remaining behind has the formula Fe_2HO . It combines very easily with weak acids, and for this reason is an effectual antidote to arsenic, which forms with it an insoluble salt. It cannot be dried without losing water and being converted into oxyhydrate of the formula $\text{Fe}_2\text{O}_2\cdot 2\text{HO}$, which has a more decided reddish tint and combines less readily with acids, and not at all with arsenious acid. This change is retarded by keeping the hydrate, as obtained by the above process, mixed with water in the form of a magma; but after some time it parts with half its water of hydration, forming the reddish-brown ferric oxyhydrate, $\text{Fe}_2\text{O}_3\cdot\text{Fe}_2\text{HO}$, which has lost the power of combining with weak acids, such as arsenious or acetic acid. A similar effect may be wholly or partly obtained during the preparation of the hydrate if the mixture be allowed to become hot. Its effectiveness as an antidote is due to two conditions—the making of the hydrate at the ordinary, not at an elevated, temperature, and its recent preparation; the magma with water should be smooth, not granular, and should be easily soluble in acetic acid without effervescence; if insoluble, it is not effectual as an antidote to arsenic.

But since the apothecary does not receive previous notice when the antidote will be required, it is best to make it fresh, when needed, by a process which will occupy but a few minutes. This may be accomplished by at once collecting upon a strainer and expressing as directed by the United States Pharmacopœia; the mixture will then contain some ammonium sulphate and a little ammonia; the latter, however, should be scarcely recognizable by the odor. The same object is attained extemporaneously by substituting magnesia for the more caustic ammonia or soda. (See FERRI OXID. HYDRAT. C. MAGN., p. 690.)

Off. Prep.—Emplastrum ferri, Trochisci ferri, U. S.; for these purposes the above magma is to be dried at a temperature not exceeding 80°C . (176°F .).

Other Forms of Ferric Oxide.—FERRI PEROXIDUM HYDRATUM, Br.; Ferrum oxydatum fuscum, Ferrum hydricum, Oxydum ferricum hydratum, Ferrugo, Rubigo.—Hydrated peroxide of iron, Ferric hydrate, E.; Hydrate ferrique, Sesquioxyde de fer hydraté, Hydrate de sesquioxyde de fer sec, Fr.; Eisenoxydhydrat, Ferrihydrat, G. Formula $\text{Fe}_2\text{O}_3\cdot 2\text{H}_2\text{O} = \text{Fe}_2\text{O}_2\cdot 2\text{HO}$. Molecular weight 177.8.—It is obtained by drying the moist ferric hydrate described above at a temperature not exceeding 100°C . (212°F .), and is identical with the ferric hydrate used by the U. S. P. for preparing iron plaster and troches of iron. It is of a dark red-brown color, and is nearly insoluble in acetic acid, but should dissolve freely and without effervescence in diluted hydrochloric acid.

FERRI SUBCARBONAS, U. S. 1870, CROCIUS MARTIS APERITIVUS (APERIENS).—Subcarbonate of iron,

E. : Safran de mars apéritif, *Fr.* : Eisensafran, *G.*—It is prepared by mixing solutions of 8 ounces of ferrous sulphate and 9 ounces of sodium carbonate, washing thoroughly with water, and drying without heat. The French Codex directs ferrous sulphate 15 parts and sodium carbonate 18 parts.

On mixing a solution of sodium carbonate with a solution of pure ferrous sulphate in boiled water, a white precipitate of ferrous carbonate is obtained, which in contact with the air rapidly darkens, changing in color through various shades of green, blue, and olive into brown, carbonic acid gas being at the same time given off. This change of color is accompanied with its conversion into ferric hydrate, with the exception of small and variable proportions of ferrous carbonate, which escape oxidation. This preparation must therefore be regarded as identical, or nearly so, with ferric hydrate.

It is an amorphous reddish-brown powder, inodorous and almost tasteless, and closely resembling ferric hydrate. Dilute hydrochloric acid dissolves it with slight effervescence, the yellow liquid yielding blue precipitates with ferricyanide (difference from pure ferric hydrate) and ferrocyanide of potassium, but not with barium chloride (absence of sulphates). If it has been dried at an elevated temperature it is of a brighter red color, does not readily dissolve in warm dilute hydrochloric acid, and consists mainly of the oxyhydrate, $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. Dried at ordinary temperature, it consists chiefly of the oxyhydrate, $\text{Fe}_2\text{O}_3 \cdot \text{Fe}_2\text{6HO}$.

FERRI OXIDUM RUBRUM, CROCUS MARTIS ASTRINGENS, COLCOTHAR, CAPUT MORTUUM.—Ferric oxide, *E.* : Colcothar, Safran de mars astringent, *Fr.* : Eisenoxyd, Rother Eisensafran, Englisch-Roth, Tottenkopf, *G.*—It is obtained by heating to redness either one of the above hydrates or by igniting ferrous sulphate in contact with air, when the salt is decomposed, water and sulphuric and sulphurous acids being given off. It is brown-red, more or less gritty, inodorous, tasteless, and insoluble in diluted acids. It is no longer employed medicinally, the ferric hydrate being used instead, but it is extensively used in the arts. It forms the main constituent of iron paint, which is sold as *English red*, *Berlin red* (Minium de fer, *Fr.* : Eisenmennige, *G.*), and under various other names, and usually consists of ferric oxide mixed with from 5 to 50 per cent. of alumina or other insoluble compound. When obtained as a fine powder by elutriation it is known as *polishing rouge*, *terre douce de vitriol*, *rouge anglais*, *Polirroth*, and employed for polishing metals. The mineral *hematite* or *red hematite*, *ferret d'Espagne*, *sanguine*, *Blutstein*, is ferric oxide, while the various *brown hematites* are different ferric hydrates.

FERRUM OXIDATUM SACCHARATUM SOLUBILE, *P. G.*—Soluble saccharated oxide of iron, Saccharated iron, *E.* : Saccharate de fer, Saccharure d'oxyde de fer soluble, *Fr.* : Eisenzucker, Lösliches Eisenoxyd, *G.*—Dissolve sugar 9 parts in distilled water 9 parts; add solution of ferric chloride (spec. grav. 1.281) 30 parts, and afterward, with continued stirring, a cold solution prepared of sodium carbonate 24 parts and hot water 48 parts; after the extrication of most of the carbonic acid gas add soda solution (sp. gr. 1.160) 24 parts, and when the precipitate has dissolved add powdered sodium bicarbonate 9 parts, followed by boiling water 600 parts, and set aside; decant the clear liquid, and wash the precipitate twice with boiling water 400 parts by decantation, and afterward upon a strainer, until the filtrate becomes merely opalescent with test solution of silver nitrate; express, mix the residue with powdered sugar 50 parts, dry at the heat of a steam-bath, add sufficient sugar to make the weight of the mixture 100 parts, and rub into a uniform powder. —*P. G.*

Ferric salts yield with alkali carbonates precipitates of ferric hydrate, but in the presence of sugar a compound with the latter is produced which is soluble in pure water and in caustic alkalies, but not in saline solutions. The solution of this precipitate in caustic soda and its reprecipitation by sodium bicarbonate and the immediate addition of boiling water, effects its separation in a denser condition, in which it may be more readily washed. The washing is not continued until all the carbonate and chloride of sodium has been removed, since the water would then dissolve the ferric compound. The last portions of the mother-liquor are removed by pressure, and the residue is mixed with sugar and dried as directed. It is a reddish-brown powder, has a sweet and mild chalybeate taste, and is entirely soluble in distilled water, yielding a deep reddish-brown solution of a feeble alkaline reaction. It contains 3 per cent. of metallic iron. The aqueous solution is not altered by potassium ferrocyanide, except after the addition of hydrochloric acid, when it is colored a dingy green, then dark-blue, a precipitate being slowly produced.

SYRUPUS FERRI OXYDATI SOLUBILIS, *P. G.*—Syrup of soluble ferric oxide, *E.* : Sirop d'oxyde de fer soluble, Sirop de saccharate de fer, *Fr.* : Eisensyrup, *G.*—Soluble saccharated oxide of iron, distilled water, and simple syrup, of each equal parts; dissolve. It is of a deep red-brown color and contains 1 per cent. of iron.

Medical Action and Uses.—Hydrated oxide of iron is chiefly used as an antidote to arsenic. But although the chemical relations of an arsenical solution may favor the precipitation of its arsenic by freshly-prepared hydrated oxide of iron, there is good reason to suppose that in ordinary cases of arsenical poisoning the greater part of the poison remains in the stomach undissolved, and that the iron, in so far as it is useful, operates chiefly as a mechanical antidote by enveloping the arsenic and shielding the stomach until the bulk of the mass or an emetic causes its discharge, in the same manner as the subcarbonate of iron does in similar cases. This statement is inferred from the fact that a very large excess of the oxide is essential to its efficiency.

The *subcarbonate of iron* of the previous editions of the Pharmacopœia seems to have been discarded on account of its speedily losing its original character by the action of the oxygen of the atmosphere. Whether or not that change impairs its therapeutic virtues is perhaps not so readily determined. At all events, it is one of the oldest pharmaceutical preparations of iron, and was intended to imitate and take the place of rust of iron, which from time immemorial had been used in medicine. It continues to be one of the most employed members of its class, but is ineligible whenever it is desired to introduce a large amount of iron into the blood. It has been recommended in all forms of *anæmia* and *anæmic chlorosis*, and in *neuralgia*, *chorea*, and other nervous affections depending upon a deficiency of red corpuscles in the blood. In a disease of a different order, *tetanus*, a number of cures have been attributed to this medicine, but of late years it has been entirely supplanted by other means, and the question of its utility is unsettled. Subcarbonate of iron in large doses, mixed with water, may be resorted to when the hydrated peroxide cannot be procured in cases of poisoning by *arsenious acid*. Four grave cases of poisoning by very large doses of arsenious acid were treated in this manner by Leale, and all recovered (*Amer. Jour. of Med. Sci.*, Jan. 1880, p. 80). The dose of subcarbonate of iron is from 5 grains (Gm. 0.30) upward. In some cases of neuralgia it has been taken by the teaspoonful. Caution should be exercised, lest it accumulate in the bowels and obstruct them.

For the reasons now given the subcarbonate has been supplanted by the oxide of iron, protected by the sugar surrounding it from peroxidation. It is probable that from this cause it more readily enters into combination with the acids of the stomach and enters the circulation, so that for all the purposes above mentioned it is more suitable than the old subcarbonate of iron, the case of arsenical poisoning alone excepted. In that case the subcarbonate no doubt acts partly by its mass in a mechanical manner, and partly by combining with the arsenious acid. The soluble saccharated carbonate is one of the most efficient of all the ferruginous preparations, and one of the most acceptable to the stomach. It should be taken a short time before meals to ensure its thorough solution and absorption, and in doses of from 3 to 10 or 15 grains (Gm. 0.20–1). Powdered "subcarbonate of iron" is one of the many dry powders which have been used in the treatment of indolent *ulcers*. *Syrup of soluble oxide of iron* is a convenient form for the administration of iron to children, and in teaspoonful doses.

FERRI OXIDUM HYDRATUM CUM MAGNESIA.—HYDRATED OXIDE OF IRON WITH MAGNESIA.

Antidotum arsenic, P. G.—*Antidote to arsenic*, E.; *Contre-poison de l'arsenic*, Fr.; *Gegengift des Arseniks*, G.

Preparation.—Solution of Tersulphate of Iron 1000 grains (65 Gm. or 13½ fluidrachms); Magnesia 150 grains (10.0 Gm.); Water a sufficient quantity. Mix the solution of tersulphate of iron with twice its weight (4½ fluidounces) of water, and keep the mixture in a well-stopped bottle. Rub the magnesia with water to a smooth and thin mixture; transfer this to a bottle capable of holding 32 fluidounces or about 1 liter, and fill it up with water. When the preparation is wanted for use, mix the two liquids by adding the magnesia mixture gradually to the iron solution, and shake them together until a homogeneous mass results. *Note.*—The diluted solution of tersulphate of iron and the mixture of magnesia with water should always be kept on hand, ready for immediate use.—*U. S.*

A similar preparation has been contained in the German Pharmacopœia, which now orders solution of ferric sulphate (sp. gr. 1.429) 100 parts with water 250 parts, and magnesia 15 parts with water 250 parts. These proportions agree nearly with the older formula. There does not appear to be any necessity for mixing the magnesia with about 100 times its weight of water; about 15 times its weight (or, for the above quantity, 8 or 9 fluidounces) of water would be sufficient. This is conveniently kept in a quart bottle, and when needed the diluted iron solution should be gradually added, with vigorous shaking, to the magnesia mixture, so as to prevent the formation of a basic insoluble iron salt. The magnesia is used in excess, more than is necessary for separating all the ferric hydrate, and the mixture is prevented from becoming heated by the previous diffusion of the magnesia in water. Neither filtration nor straining is requisite, the compounds of the mixture being ferric and magnesium hydrates and magnesium sulphate, none of which has any caustic or otherwise injurious effect nor forms a soluble compound with arsenic. The mixture being made only when needed, the ferric hydrate is in that

condition in which it readily combines with arsenious acid and has not become inert for the purpose by long keeping.

Action and Uses.—If freshly made and promptly administered in large doses, it is probable that this mixture is a more efficient antidote to arsenic than either of its ingredients would be alone.

FERRI OXIDUM MAGNETICUM, Br.—MAGNETIC OXIDE OF IRON.

Ferrum oxydatum magneticum, Oxydum ferroso-ferricum.—Black oxide of iron, E.; *Oxyde ferroso-ferrique, Oxyde de fer noir (magnétique), Ethiops martial*, Fr.; *Magneteisen, Ferroferrioxyd, Eisenoxyd-Oxydul*, G.

Formula $\text{Fe}_3\text{O}_4 = \text{FeO} \cdot \text{Fe}_2\text{O}_3$. Molecular weight 231.7.

Preparation.—Take of Solution of Persulphate of Iron $5\frac{1}{2}$ fluidounces; Sulphate of Iron 2 ounces; Solution of Soda 4 pints; Distilled Water a sufficiency. Dissolve the sulphate of iron in 2 pints of the water, and add to it the solution of persulphate of iron; then mix this with the solution of soda, stirring them well together. Boil the mixture; let it stand for 2 hours, stirring it occasionally; then put it on a calico filter, and when the liquid has drained away, wash the precipitate with distilled water until what passes through the filter ceases to give a precipitate with chloride of barium. Lastly, dry the precipitate at a temperature not exceeding 120°F .—Br.

Magnetic oxide, which is found in Sweden as magnetic iron ore, consists of 1 molecule each of ferrous and ferric oxides. When solutions of ferrous and ferric salts are mixed in molecular proportions, and then precipitated by a caustic alkali, the same compound is thrown down in a hydrated condition. The mixture should without delay be boiled for some time until the precipitate has become denser and settles readily. It may then without difficulty be washed by decantation, and finally upon the filter, without being prone to oxidation, as before the boiling.

Properties.—It is an inodorous and tasteless brownish-black powder, which is strongly attracted by the magnet and dissolves without effervescence in warm hydrochloric acid diluted with half its volume of water. This solution yields blue precipitates with both ferrocyanide and ferrieyanide of potassium. When heated in a test-tube it gives off moisture, and when the heat is continued in contact with the air red ferric oxide is left. Lefort (1852) found magnetic oxide of iron to contain 1 molecule, or 7.2 per cent., of water. According to the British Pharmacopœia, it contains about 20 per cent.

Its purity is ascertained by the tests given, and by sulphuretted hydrogen added to the dilute solution in hydrochloric acid, which should produce only a white turbidity from separated sulphur, but not a black precipitate (absence of copper, etc.). Should it have been insufficiently washed, the alkaline sulphates or chlorides may be detected in the distilled water shaken with a portion of the oxide.

Under the name of *Ethiops martialis* various pharmacopœias formerly recognized black ferroso-ferric oxide, which varied in composition according to the different methods of preparation.

Medical Action and Uses.—This preparation has been but little used of late, owing to the want of uniformity in its composition. It is, however, rich in iron, and may be prescribed in all cases for which the subcarbonate is employed. The dose is from 5 to 20 grains (Gm. 0.30–1.30), and should be taken after meals.

FERRI PHOSPHAS, U. S.—PHOSPHATE OF IRON.

Ferri et sodii citro-phosphas; Ferrum phosphoricum cum natrio citrico.—Soluble ferric phosphate, *Sodio-ferric citro-phosphate*, E.; *Citro-phosphate de fer et de soude*, Fr.; *Natrium-ferricitrophosphat*, G.

Preparation.—Citrate of Iron 5 parts (5 oz. av.); Phosphate of Sodium 6 parts (6 oz. av.); Distilled Water 10 parts (10 oz. av. or $9\frac{1}{2}$ fluidounces). Dissolve the citrate of iron in the distilled water by heating on a water-bath. To this solution add the phosphate of sodium, and stir constantly until it is dissolved. Evaporate the solution, at a temperature not exceeding 60°C . (140°F .), to the consistence of thick syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—U. S.

The pharmacopœial names for this compound are incorrect, and should be changed, although analogous to those of the medicinal pyrophosphate of iron; both might very appropriately be designated as soluble ferric phosphate and pyrophosphate, to distinguish

them from these salts, which are insoluble in water. Ferric citrate and sodium phosphate are mixed in the proportion of their molecular weights as given by the Pharmacopœia; the dark-red color of the liquid changes to green, when on evaporation the amorphous double salt is left behind and obtained in scales. The yield is 7 parts (7 oz. av.).

Properties.—Sodio-ferric citro-phosphate is in thin, bright-green, transparent scales, permanent in dry air when excluded from the light, but turning dark on exposure to light, odorless, having an acidulous, slightly saline taste and a slightly acid reaction; freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt is rendered blue by test solution of ferrocyanide of potassium, but does not yield a blue precipitate with this reagent unless it has been acidulated with hydrochloric acid. When heated with solution of potassa in excess a brown-red precipitate is thrown down, and the filtrate, after being supersaturated with acetic acid, yields a light-yellow precipitate with test solution of nitrate of silver (difference from pyrophosphate). 100 parts of the salt represent about 13.5 parts of metallic iron."—*U. S.*

Composition.—According to R. Rother, the salt contains 1 molecule of water, and its formula is $\text{FePO}_4 \cdot \text{Na}_2\text{H}(\text{C}_6\text{H}_5\text{O}_7) \cdot \text{H}_2\text{O}$, the molecular weight being 405. (See papers by R. Rother on this and allied compounds in *Amer. Jour. Phar.*, 1876, p. 171, and 1883, p. 165.)

Off. Prep.—Syrupus ferri quiniæ et strychninæ phosphatum, *U. S.*

True Phosphates of Iron.—**FERRI PHOSPHAS.** *Br.*—Fertum phosphoricum, Phosphas ferroso-ferricus.—Phosphate of iron, Ferroso-ferric phosphate, *E.*; Phosphate de fer, Phosphate ferroso-ferrique, *Fr.*; Ferroferriphosphat, Phosphorsäures Eisenoxydul-Oxyd, *G.* Formula $\text{Fe}_2\text{PO}_4 \cdot \text{FePO}_4 \cdot 12\text{H}_2\text{O}$; molecular weight 724.6.—Take of sulphate of iron 3 ounces; phosphate of soda $2\frac{1}{2}$ ounces; acetate of soda 1 ounce; boiling distilled water 4 pints. Dissolve the sulphate of iron in one-half of the water, and the phosphate and acetate of soda in the remaining half. Mix the two solutions, and after careful stirring transfer the precipitate to a calico filter, and wash it with hot distilled water till the filtrate ceases to give a precipitate with chloride of barium. Finally, dry the precipitate at a temperature not exceeding 120°F. —*Br.*

The mineral *virianite*, which forms pale-blue crystals, is mainly ferrous phosphate. On bringing together solutions of ferrous sulphate and sodium phosphate a white precipitate of ferrous phosphate is produced, which on exposure and during the washing is oxidized, and acquires a more or less blue, greenish-blue, or grayish-blue color. During the reaction a portion of the sulphuric acid is set free, and retains phosphate of iron in solution, to obtain which sodium acetate is added, which, reacting with the free sulphuric acid, forms sodium sulphate and free acetic acid, in which the phosphates of iron are insoluble. The French Codex omits this addition, and uses the salts in the proportion of ferrous sulphate 1 part and sodium phosphate 3 parts. The washing of the precipitate must be continued until the filtrate fails to give a reaction for sulphuric acid.

Thus prepared, it is a tasteless and inodorous bluish powder, varying somewhat in shade. It is insoluble in water, but dissolves in hydrochloric acid, yielding a yellow solution in which dark-blue precipitates are produced by both ferro- and ferricyanide of potassium. If the acid solution is treated with sufficient tartaric acid, and then with an excess of ammonia, no precipitate is produced, but on the addition of sulphate of magnesium a white precipitate of ammonio-magnesium phosphate falls. When the powder is boiled with caustic soda the filtrate, after being neutralized, yields a yellow precipitate with nitrate of silver. Both precipitates indicate phosphoric acid. The chemical composition varies to some extent, and is influenced by its exposure to the atmosphere while moist, the temperature at which it is dried, etc. The above formula is that of Rammelsberg. Wittstein obtained a somewhat different result. The British Pharmacopœia regards it as ferrous phosphate partially oxidated, and requires 20 grains of it dissolved in hydrochloric acid to give a blue precipitate with potassium ferricyanide until 250 grain-measures of the volumetric solution of potassium bichromate have been added.

The salt should yield nothing to hot distilled water (insufficient washing), and the solution in hydrochloric acid should yield only a white turbidity of sulphur with sulphuretted hydrogen, but not a black (copper, etc.) or a yellow (arsenic) precipitate. The same solution, digested with bright copper, should not form a dark deposit of arsenic upon the metal.

FERRI PHOSPHAS ALBUS, PHOSPHAS FERRICUS.—Ferric phosphate, White phosphate of iron, *E.*; Phosphate ferrique, *Fr.*; Ferriphosphat, *G.* $\text{Fe}_2\text{PO}_4 \cdot 4\text{H}_2\text{O}$; molecular weight 373.8.—On mixing 4 fluidounces of solution of tersulphate of iron with the solution of 1 ounce of sodium acetate, and adding solution of sodium phosphate, a white precipitate

of ferric phosphate is obtained. After washing and drying at 100° C. it is a white or yellowish-white tasteless powder having the composition stated, is decomposed by alkalis, and dissolves readily in dilute mineral acids, in citric and tartaric acid, and in alkaline citrates, the latter solutions having a green color. The freshly precipitated and washed salt, mixed with water until the mixture contains 1.0 or 1.2 per cent. of ferric phosphate, has been used under the name of *Lac ferri, milk of iron*.

Medical Action and Uses.—Owing to its insolubility in water phosphate of iron must be given in pill or in powder, of which the latter is preferable, in the *dose* of from 5 to 10 grains (Gm. 0.30–0.60). It is extremely doubtful whether the phosphoric acid in its composition confers any special virtues upon it.

FERRI PYROPHOSPHAS, U. S.—PYROPHOSPHATE OF IRON.

Ferri et sodii citro-pyrophosphas, Ferrum pyrophosphoricum cum sodio citrico, Pyrophosphas ferricus cum citrate sodico.—Pyrophosphate of iron with sodium citrate, *Sodio-ferric citro-pyrophosphate*, E.; *Citro-pyrophosphate de fer et de soude*, Fr.; *Pyrophosphorsaures Eisenoxyd mit Citronensaurem Natron*, G.

Preparation.—Citrate of Iron 9 parts (9 oz. av.); Pyrophosphate of Sodium 10 parts (10 oz. av.); Distilled Water 18 parts (18 oz. av. or $17\frac{1}{2}$ fluidounces). Dissolve the citrate of iron in the distilled water by heating on a water-bath. To this solution add the pyrophosphate of sodium, and stir constantly until it is dissolved. Evaporate the solution, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stopped bottles in a dark place.—U. S.

On precipitating a solution of sodium pyrophosphate by ferric sulphate a white precipitate of *ferric pyrophosphate*, $\text{Fe}_3\text{P}_2\text{O}_7$, is obtained, which, like other insoluble ferric salts, is readily soluble in alkaline citrates, forming green solutions. Formerly ammonium citrate was used for this purpose, but, owing to the slow volatilization of the ammonia, the salt gradually became insoluble. Sodium phosphate is not subject to the same disadvantage. The present formula also proceeds inversely from the former one, and instead of dissolving the ferric pyrophosphate in the alkaline citrate now adopts the suggestion of Mr. Rother (1876), and directs the alkali pyrophosphate to be mixed with ferric citrate, when, practically, the same compound will be produced. The relative proportions, however, have been changed, the salts being used in the approximate proportions of 2 molecules of ferric citrate and 3 of crystallized sodium pyrophosphate. The yield is $14\frac{1}{2}$ parts ($14\frac{1}{2}$ oz. av.).

Properties.—The salt is obtained in inodorous transparent apple-green scales, which are permanent in dry air when excluded from the light, but turn dark on exposure to light. The salt has an acidulous, slightly saline, and scarcely chalybeate taste and a slightly acid reaction, is insoluble in alcohol, but dissolves freely in water, yielding a greenish solution; this gives with potassium ferrocyanide a blue color, but no precipitate unless acidulated with hydrochloric acid. Excess of ammonia produces no precipitate, but boiling with caustic potassa yields a yellowish-white, and if an excess of the latter be used a red-brown, precipitate; and the filtrate separated from this precipitate, after being supersaturated with acetic acid, yields a white precipitate with test solution of nitrate of silver (difference from phosphate). 100 parts of the salt represent about 11.5 parts of metallic iron, U. S.

Composition.—This preparation is evidently of a complex nature. Regarding the chemical composition of this and similar preparations two views have been entertained. According to the one, they are double salts of ferric pyrophosphate and alkali citrate; according to the other, which has been advocated by Rother (1876), they should be regarded as mixtures of alkali-ferric pyrophosphate, $\text{Fe}_3\text{P}_2\text{O}_7 \cdot 3\text{Na}_4\text{P}_2\text{O}_7$, with alkali-ferric citrate and ferric citrate. The formula given for the double pyrophosphate corresponds with that of Gladstone for sodio-ferric pyrophosphate, for which Fleitmann and Persoz (1848) give the formula $\text{Fe}_4(\text{P}_2\text{O}_7)_3 \cdot 2\text{Na}_4\text{P}_2\text{O}_7$.

Allied Salt.—FERRI ET SODII PYROPHOSPHAS, Natrium pyrophosphoricum ferratum.—Sodio-ferric pyrophosphate, E.; *Pyrophosphate de fer et de soude*, Fr.; *Natrium ferri-pyrophosphat*, G.—It is prepared by adding to a solution of 200 parts of sodium pyrophosphate in 400 parts of water so much ferric chloride in aqueous solution that a permanent precipitate is not produced, and mixing with the greenish liquid 1000 parts of alcohol. A white amorphous powder is thus obtained, which, according to Fleitmann, contains 7 molecules (9 per cent.) of water, and dissolves slowly in water, yielding a greenish solution; this on boiling separates a white precipitate,

acquires with ammonia a red color, is not precipitated by alkaline carbonates, phosphates, or acetates, but with chloride of sodium yields a precipitate of the double salt, while the addition of ferric chloride causes the precipitation of ferric pyrophosphate.

Medical Action and Uses.—The tastelessness, solubility, and richness in iron of this salt render it one of the best ferruginous preparations. *Dose*, from 2 to 5 grains (Gm. 0.18–0.30). The dose of pyrophosphate of iron and sodium is stated at from 2 to 5 grains (Gm. 0.10–0.30).

SALICYLATE OF IRON has had attributed to it qualities which are unlike those of any other iron salt, such as “promoting secretion and stimulating the skin,” while it “promotes perspiration, lowers the temperature, and reduces the pulse.” It has been recommended for *diphtheria*, *aphthæ*, *erysipelas*, etc. (White, *Glasgow Med. Jour.*, Aug. 1879).

FERRI SULPHAS, U. S., Br.—SULPHATE OF IRON.

Ferrum sulfuricum, P. G.; *Sulfas ferrosus*, *Ferrum vitriolatum purum*, *Vitriolum martis purum*.—*Ferrous sulphate*, E.; *Sulfate (Protosulfate) de fer*, *Sulfate ferreux*, Fr.; *Ferrosulfat*, *Schwefelsaures Eisenoxydul*, G.

Formula of crystallized or precipitated ferrous sulphate $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$; molecular weight 277.9; of exsiccated ferrous sulphate $\text{FeSO}_4 \cdot \text{H}_2\text{O}$; mol. weight 169.9.

Preparation.—Take of Iron Wire 4 ounces; Sulphuric Acid 4 fluidounces; Distilled Water $1\frac{1}{2}$ pints. Pour the water on the iron placed in a porcelain dish, add the sulphuric acid, and when the disengagement of gas has nearly ceased boil for 10 minutes. Filter now through paper, and after the lapse of 24 hours separate the crystals which have been deposited from the solution. Let these be dried on filtering-paper placed on porous bricks, and preserved in a stoppered bottle.—*Br.*

Ferrous sulphate is obtained on a large scale from alum shale and by roasting iron pyrites, exposing it to the air, and exhausting the mass with water; also by passing solutions of copper sulphate over scraps of iron, whereby copper is precipitated, the iron entering into solution. It is also obtained as a by-product in various manufactures where sulphuric acid is used for the purpose of purifying certain products. The article thus obtained is usually impure and not fit for medicinal purposes, except for disinfecting, and in this impure state is known in commerce as *copperas*, or *green vitriol* (*Coquerose verte*, *Vitriol vert*, Fr.; *Kupferwasser*, *Grüner Vitriol*, G.). For medicinal use it should be prepared directly from sulphuric acid acting upon iron wire or clean iron filings in the presence of water, when hydrogen is evolved, ferrous sulphate remaining in solution; $\text{Fe}_2 + 2\text{H}_2\text{SO}_4$ yields $2\text{H}_2 + 2\text{FeSO}_4$. The salt is prone to oxidation if its chemically neutral solution is evaporated to crystallization, but in the presence of some free sulphuric acid yields crystals which are far more permanent. This explains the necessity of having some free sulphuric acid in the liquid from which ferrous sulphate is crystallized. The crystals are collected upon a diaphragm, washed rapidly with a little water, and, according to the French Codex, with a little alcohol, to remove the mother-liquor, and then dried.

Properties.—Ferrous sulphate is in transparent bluish-green monoclinic prisms, or

FIG. 123.

Crystal of Ferrous Sulphate.

sometimes in rhombic crystals having the specific gravity 1.9. When crystallized from neutral solutions the salt is pale-green, and in the presence of ferric salt of a deeper, more emerald-green, color. It is inodorous, has a styptic and somewhat saline taste, a slight acid reaction, melts by heat in its water of crystallization, leaving finally a whitish residue, and when exposed to the air effloresces and is gradually oxidized: the efflorescence takes place more rapidly above 35°C . (95°F .), and when finally heated to 115°C . (239°F .) the loss of water of crystallization amounts to 38.86 per cent. The salt is insoluble in alcohol and ether, but dissolves at 10°C . (50°F .) in 1.64, at 30°C . (86°F .) in 0.7, and at 100°C . (212°F .) in 0.3, parts of water; according to Schiff (1857), the solution, saturated at 15°C . (59°F .), contains 1 part of the crystallized salt to 1.71 parts of water. The aqueous solution yields a white precipitate insoluble in hydrochloric acid with barium chloride, a dark-blue one with potassium ferriyanide, and a bluish-white one with potassium ferrocyanide.

Tests.—Impurities are rarely present if the salt has been prepared from iron and sulphuric acid. The aqueous solution treated with hydrosulphuric acid should yield not more than a faint white turbidity of sulphur (limit of ferric salt), should not give

a blackish precipitate (copper, etc.), and when completely precipitated by sulphhydrate of ammonium the filtrate on evaporation and ignition should leave no residue (magnesium, alkalis). The aqueous solution, after being oxidized with nitric acid and supersaturated with ammonia, should yield a filtrate which is not affected by sulphuretted hydrogen (zinc, manganese); and if the oxidized liquid be supersaturated with potassa solution, the filtrate neutralized with hydrochloric acid and again supersaturated with ammonia, no precipitate (alumina) should occur. "If 4.167 Gm. of sulphate of iron are dissolved in water acidified with diluted sulphuric acid, and the solution treated with volumetric solution of bichromate of potassium until a drop no longer gives a blue color with test-solution of ferrieyanide of potassium, the required number of Ccm. of the volumetric solution multiplied by 2 equals the percentage of unoxidized ferrous sulphate in crystals."—*U. S.*

Pharmaceutical Uses.—Nearly all the official compounds of iron, with the exception of the chloride, iodide, sulphide, and nitrate, are prepared from the sulphate, either directly or indirectly. Ferrous sulphate is used in preparing *Mistura ferri comp.*, *U. S.*, *Br.*; *Pil. aloes et ferri, Br.*; *Massa ferri carbonatis, Pil. ferri comp., U. S.*

FERRI SULPHAS PRÆCIPITATUS, U. S.; **FERRI SULPHAS GRANULATA, Br.**—Precipitated or granulated sulphate of iron or ferrous sulphate, *E.*; Sulfate ferreux précipité, *Fr.*; Präcipitirtes Ferrosulfat, *G.*—Sulphate of iron 100 parts ($12\frac{1}{2}$ oz. av.); distilled water 170 parts ($21\frac{1}{4}$ oz. av. or $20\frac{3}{4}$ fluidounces); sulphuric acid 4 parts ($\frac{1}{2}$ oz. av.); alcohol a sufficient quantity. Dissolve the sulphate of iron in the distilled water, previously mixed with the sulphuric acid, and filter the solution. Allow the filtrate to become cold, pour it gradually and while stirring into an equal volume (26 fluidounces) of alcohol, and set the mixture aside for 1 day in a well-covered vessel. Drain the crystalline powder which has settled in a funnel, wash it with alcohol until the washings cease to redden blue litmus-paper, fold it in a piece of muslin, and press it gently. Finally, spread the powder on bibulous paper and dry it quickly in the sunlight or in a dry-room at the ordinary temperature, and keep it in well-stopped bottles.—*U. S.*

The British Pharmacopœia gives the same directions as for the crystallized salt, except that on filtering the solution is collected in a jar containing 8 fluidounces of alcohol, which quantity is insufficient for precipitating all the ferrous sulphate. The German Pharmacopœia likewise directs the salt to be prepared from iron wire, but uses about an equal volume of alcohol for precipitating the warm aqueous solution. The salt thus prepared is a very pale bluish-green powder, which, if it has been properly dried, is less readily oxidized on exposure than the crystals, but in other respects shows precisely the same behavior as the crystallized salt, and is tested in the same manner.

FERRI SULPHAS EXSICCATUS, U. S., Br.; **FERRUM SULFURICUM SICCUM, P. G.**—Dried (exsiccated) sulphate of iron or ferrous sulphate, *E.*; Sulfate ferreux desséché, *Fr.*; Entwässertes Ferrosulfat, *G.*—Sulphate of iron, in coarse powder, a convenient quantity. Expose the sulphate of iron in an unglazed earthen vessel to a moderate heat, occasionally stirring, until it has effloresced. Then increase the heat to 149° C. (300° F.), and maintain it at that temperature until the salt ceases to lose weight. Lastly, reduce the residue to fine powder and keep it in well-stopped bottles.—*U. S.*

The process of the British Pharmacopœia is the same, except that a porcelain or iron dish is used and the heat permitted to be raised to about 204° C. (400° F.). The yield is about 61 per cent. The German Pharmacopœia employs only the heat of a water-bath, at which the loss amounts to 35 or 36 per cent. Crystallized ferrous sulphate contains 45.3 per cent. of water of crystallization, a portion of which is lost in a dry atmosphere at the ordinary temperature, the remainder, except 1 molecule, at 115° C. (239° F.). The last molecule of water is expelled only at about 280° C. (536° F.), and, if proper care be taken, without the loss of sulphuric acid.

Exsiccated ferrous sulphate forms a grayish-white powder which dissolves slowly in cold, more rapidly in hot, water, leaving only a small quantity of ferric oxysulphate. Otherwise, the behavior and tests of purity are the same as for the crystalline salt, nearly 10 parts of which are represented by 6 parts of the exsiccated salt.

Medical Action and Uses.—The intense astringency of the sulphates of iron renders them, as a rule, ineligible for internal administration, except when it is intended to exert a directly constringing action upon the capillaries, not only of the alimentary canal, but of remote organs. If the dose much exceeds 1 or 2 grains (Gm. 0.06–0.12) it is apt to occasion gastric pain and vomiting, and the prolonged use of even smaller doses is not free from the risk of impairing the digestive function. Besides passive *hæmorrhages*, it is well adapted to control excessive secretions produced by debility, as *sweating, chronic diarrhœa, leucorrhœa, gleet, and hydruria*. Externally, it has been used as an

application to the skin in superficial traumatic *erysipelas*, but it is quite useless in the idiopathic form of the disease. A solution of $\frac{1}{2}$ ounce (Gm. 16) of the salt in a pint of water, or an ointment containing 2 drachms (Gm. 8) to the ounce of lard, may be employed in the former affection. An ointment made with 1 or 2 parts of the dried sulphate to 30 of lard is a useful application in cases of obstinate local diseases of the skin, such as eczema, intertrigo, and impetigo. It may also aid in healing the sores occasioned by *rupia*, *ecthyma*, *syphilis*, and *scrofula*, but has no advantage over zinc ointment for this purpose.

FERRI SULPHURETUM.—SULPHURET OF IRON.

Sulphuretum ferrosium.—*Sulphide of iron*, E.; *Sulfure de fer*, Fr.; *Schwefeleisen*, G.

Formula FeS . Molecular weight 87.9.

Preparation.—Iron unites with sulphur in various proportions, some of the compounds, like iron pyrites, FeS_2 , being found in nature. The monosulphide, which is employed for generating sulphuretted hydrogen, is made by mixing 3 parts of iron filings with 2 parts of sublimed sulphur, introducing the mixture in small portions into a crucible heated to bright redness and kept covered after each addition; or, a rod of iron is raised nearly to a white heat and then brought into contact with sulphur; ferrous sulphuret will at once form and melt, and should be permitted to drop into cold water to solidify.

Properties.—It is in yellowish-black or blackish masses or irregular pieces, which have a metallic lustre and are permanent in dry air, but are oxidized when kept in a damp atmosphere. It dissolves readily in dilute sulphuric or hydrochloric acid, with the evolution of sulphuretted hydrogen, and without leaving any residue when the sulphuret is pure. As met with, it sometimes contains an excess of sulphur, but usually has an excess of iron, and the sulphuretted hydrogen evolved is mixed with hydrogen.

Sulphuretted hydrogen, *hydrogen sulphide*, or *hydrosulphuric acid* is a colorless gas having a disgusting odor suggesting that of rotten eggs. Its specific gravity is 1.19; water dissolves three times its volume of the gas; the solution is not permanent in the air, but is oxidized, water being formed and white sulphur deposited. The formula of sulphuretted hydrogen is H_2S , its molecular weight 34.

This compound has no direct medicinal value. It is used for the production of hydrosulphuric acid.

FERRI VALERIANAS, U. S.—VALERIANATE OF IRON.

Ferrum valerianicum.—*Ferric valerianate*, E.; *Valérianate de fer*, Fr.; *Ferrivalerianat*, *Baldriansaures Eisenoxyd*, G.

Preparation.—This salt is best obtained by adding to a cold solution of ferric sulphate or ferric chloride a cold solution of sodium valerianate as long as a precipitate is produced, collecting this upon a filter, washing it with a little water, and drying it at a temperature not exceeding 20°C . (68°F). The salt is formed by double decomposition, sodium sulphate or chloride remaining in solution, while ferric valerianate is precipitated. An elevated temperature and continued washing should be avoided, since valerianic acid would be removed and a more basic salt remain behind.

Properties.—The salt is a dark brick-red light amorphous powder which has a slight odor and a taste of valerianic acid. When slowly heated it gradually parts with all its acid without melting, but when rapidly heated it fuses and gives off dense inflammable vapors having only a faint odor of valerianic acid, but a strong odor of butyric acid. The salt is with difficulty moistened with cold water, but boiling water decomposes it, gradually setting free all the acid and leaving ferric hydrate. The salt is easily soluble in hydrochloric acid (Wittstein, 1845). On treating freshly-precipitated ferric hydrate with valerianic acid, Ludwig (1849) obtained a granular dark red-brown powder which was only partly soluble in alcohol, leaving a basic salt behind.

Composition.—The formula given by the Pharmacopœia, $\text{Fe}_2(\text{C}_5\text{H}_9\text{O}_2)_6$, mol. weight 717.8, requires 22.26 per cent. Fe_2O_3 . Ludwig's alcoholic solution when spontaneously evaporated left a salt yielding 21.5 per cent. Fe_2O_3 ; the formula $\text{Fe}_2(\text{C}_5\text{H}_9\text{O}_2)_6 \cdot \text{H}_2\text{O}$ requires 21.72 per cent. Dried at 50°C . (122°F), the same salt yielded 30 per cent., and Wittstein's salt, dried at 20°C . (68°F), gave 27 per cent. Fe_2O_3 ; the formula $\text{Fe}_2(\text{C}_5\text{H}_9\text{O}_2)_6 \cdot \text{FeOC}_5\text{H}_9\text{O}_2$ requires 27.34 per cent. The salt is evidently of variable composition.

depending on the process, the care with which it has been washed, and the temperature at which it has been dried.

Medical Action and Uses.—It was expressly stated, when this preparation was first introduced into medicine, that it would be an error to regard it as a true anti-spasmodic, on account of the valerianic acid in its composition, and that its value depended mainly upon the iron it contained, the acid acting only as an adjuvant. It should have been added that the iron might be introduced into the system under many more eligible forms and in more suitable doses than were recommended for this salt. It is probably but little used, even for the affections for which it was originally recommended, and which were described as "chlorosis with hysterical or epileptiform attacks." It was prescribed in pills in the *dose* of from 1 to 3 grains (Gm. 0.05–0.15) several times a day.

FERRUM, U. S., Br.—IRON.

Mars.—*Fer*, Fr.; *Eisen*, G.

Symbol Fe. Atomicity bivalent and sexivalent (Fe_2). Atomic weight 55.9.

Metallic iron, in the form of fine, bright, and non-elastic wire, *U. S.*; wrought iron in the form of wire or nails free from oxide, *Br.*

Origin.—Iron is the most useful and one of the most widely-diffused metals in nature, being present in most rocks and soils, and generally forming one of the constituents of the ashes of plants and animals. It is rarely found in the metallic state. It is often combined with sulphur, as *iron pyrites*, more frequently oxidized, as *magnetic iron*, *spathic iron*, *hematite*, and other ores, and likewise in combination with mineral acids. It is found in large quantities in several states of North America and in Great Britain, Sweden, Germany, France, and other European countries.

The manufacture of metallic iron must of necessity vary with the nature of the ore, but the principle is in all cases the same. The ore frequently requires roasting or calcination, mainly for the purpose of rendering it more porous and better adapted for the smelting process; this process is conducted in blast-furnaces, the ore being mixed with carbonaceous matter—coke and the like—some flux, either lime or clay, being added at the same time, whereby a more readily fusible silicate of aluminium and calcium is formed, which on cooling forms the glass-like slag. The crude iron obtained from the blast-furnace is called *pig* or *cast iron*, and contains various proportions of carbon, silicon, sulphur, phosphorus, and other impurities, from which it must be purified to adapt it for various uses in the arts. In the *refining* or *puddling* process it is fused, and by stirring brought into contact with a blast of air, by which the impurities are oxidized, or the oxidation is effected with the aid of an impure oxide of iron (iron scales). The slag still remaining in the iron is then at a white heat pressed out under a steam-hammer, and the iron thus purified rolled out into bars. For many purposes a further purification is requisite.

Properties.—Iron is a grayish metal of the spec. grav. 7.7 to 7.9. Its tenacity or strength is nearly twice as great as that of any other metal commonly used, and when heated to redness it possesses a ductility admitting of its being drawn into the thinnest wire. At a white heat it becomes pasty and may be welded, but it can be fused only by the full heat of a blast-furnace, and on congealing it expands somewhat in volume. Iron remains unchanged in dry air, but in the presence of moisture its surface becomes covered with brown-red oxide (*rust*). It enters into combination with nearly all the elements, and forms the base of two important series of salts, the *ferrous* and *ferric*, in the former of which it is a dyad, Fe'' , in the latter a hexad (Fe_2)^{VI}.

Ferrous salts, when anhydrous, are mostly white, and bluish-green in the hydrated state; the oxalate is yellow. When moist or in solution they are easily oxidized on exposure to the air or under the influence of oxidizing agents. Their aqueous solutions are colored brownish-black by nitric oxide, and yield black precipitates with sulphhydrate of ammonium, and white ones, changing to green, black, and brown, with alkalis and their carbonates; the precipitation, particularly with ammonia, is incomplete. Soluble phosphates precipitate white ferrous phosphate, changing to greenish-blue; potassium ferrocyanide produces a bluish-white precipitate, changing to dark-blue, and potassium ferricyanide a dark-blue one. Ferrous solutions free from ferric salt are not affected by potassium sulphocyanide or tannin. The soluble normal ferrous salts have an acid reaction to test-paper; those insoluble in water dissolve in hydrochloric acid.

Ferric salts are either normal or basic: the normal salts, when soluble, have an acid reaction, are mostly white when anhydrous, and brown or brown-yellow when hydrated:

the basic salts are of a darker brown or reddish-brown color. Those insoluble in water dissolve in hydrochloric acid. Sulphuretted hydrogen reduces ferric to ferrous salts, sulphur being separated; ammonium sulphhydrate produces the same reduction, and afterward a black precipitate. Alkalies and alkaline carbonates added in excess separate brown ferric hydrate, in the latter case with the evolution of carbonic acid: the precipitation is prevented by the presence of tartaric acid and some other organic compounds. Alkali acetate, added in the cold, colors the solutions deep brown-red, the color disappearing on the addition of hydrochloric acid: on boiling a brown precipitate of basic ferric acetate or ferric hydrate is deposited. Solutions of ferric salts treated with metallic iron, sulphurous acid, or other deoxidizing agents are reduced to ferrous salts. Sodium phosphate precipitates white ferric phosphate, which is insoluble in acetic acid, becomes brown by ammonia, and if excess of sodium phosphate be present dissolves in ammonia with a red-brown color. Arseniate of sodium has a behavior similar to that of the phosphate. Gallo-tannic acid causes a blue-black color and precipitate (writing ink). Meconic acid and sulphocyanides color the solutions blood-red, the color produced by the latter reagent being destroyed by corrosive sublimate and by strong mineral acids. Potassium ferri-cyanide darkens the solutions of ferric salts to an olive-brown color: potassium ferrocyanide precipitates Prussian blue.

Pharmaceutical Uses.—Besides the salts of iron treated of elsewhere, the following may be noticed:

FERRI BENZOAS.—Benzoate of iron, *E.* $\text{Fe}_26(\text{C}_6\text{H}_5\text{O}_2.6\text{H}_2\text{O})$; mol. weight 945.8.—Solution of tersulphate of iron is precipitated by a concentrated solution of benzoate of sodium or of ammonium, the precipitate collected on a filter, washed with a little cold water, pressed, and dried. It is a brownish orange-colored powder having little taste, and turning brown when heated to about 135°C . (275°F .), with the loss of water: at a higher temperature benzoic acid sublimes and the salt is decomposed. Water and alcohol dissolve a portion of the compound, leaving a basic salt. Basic ferric benzoates of a reddish or pale-brownish color are obtained from solution of subsulphate of iron or of ferric chloride mixed with ammonia-water insufficient in quantity for precipitation by adding solution of benzoate of ammonium.

FERRI TANNAS.—Tannate of iron, *E.*—Ferric tannates, free from gallate and containing but little of ferrous compound, are produced by precipitating cold solutions of ferric salts with tannin; a mixture of ferrous salt and tannin exposed to the air likewise deposits ferric tannate. Wittstein (1847) found these precipitates to contain between 8.4 and 56.25 per cent. of ferric oxide, the nature of the iron salt and the order of mixing the solutions influencing the composition of the precipitate. A compound containing about one-third its weight of ferric oxide is obtained by preparing the hydrated oxide from 3 fluidounces of solution of tersulphate of iron and triturating the washed and pressed precipitate with 1 troyounce of tannin and sufficient alcohol, after which it is dried in a water-bath. Tannate of iron is a black or bluish-black powder which is decomposed by mineral and the stronger organic acids. When boiled with water the ferric is reduced to ferrous salt.

FERRI MALAS.—Malate of iron, *E.*—Impure malate of iron is recognized by several European pharmacopœias as **EXTRACTUM FERRI POMATUM**, which is prepared by digesting the expressed juice of sour apples with 3 or 4 per cent. of iron filings until the reaction has ceased, filtering, and evaporating. It has a blackish-green color, and contains a variable quantity of iron, sometimes as much as 8 per cent. 1 part of it dissolved in 9 parts of cinnamon-water, containing one-tenth its weight of alcohol, is known as **TINCTURA FERRI POMATA**, *P. G.*

Off. Prep.—Besides *Ferrum reductum* the following *chemical* compounds and mixtures are officinal: *Ferri arsenias*, *Br.*; *Ferri carbonas saccharatus*, *U. S.*, *Br.*; *Ferri chloridum*, *Ferri citras*, *U. S.*; *Ferri et ammon. citras*, *U. S.*, *Br.*; *Ferri et ammon. sulphas*, *Ferri et ammon. tartras*, *U. S.*; *Ferri et potass. tartras* (*Ferrum tartaratum*), *Ferri et quiniæ citras*, *U. S.*, *Br.*; *Ferri et strychninæ citras*, *Ferri hypophosphis*, *U. S.*; *Ferri iodidum*, *Br.*; *Ferri iodidum saccharatum*, *Ferri lactas*, *Ferri oxalas*, *U. S.*; *Ferri oxidum humidum* (*hydratum*), *U. S.*, *Br.*; *Ferri oxidum magneticum*, *Ferri peroxidum hydratum*, *Br.*; *Ferri oxid. hydrat. c. magnesia*, *Ferri phosphas*, *U. S.*, *Br.*; *Ferri pyrophosphas*, *U. S.*; *Ferri sulphas*, *Ferri sulphas exsiccatus*, *Br.*; *Ferri sulphas præcipitatus* (*granulata*), *U. S.*, *Br.*; *Ferri valerianas*, *U. S.*

The following are solutions of iron salts in water, syrup, alcohol, or wine: *Liquor ferri acetatis*, *Liq. ferri chloridi*, *Liq. ferri citratis*, *Liq. ferri et quiniæ citrat.*, *U. The following pharmaceutical preparations contain iron in various forms: *Emplastr. ferri, U. S., Br.*; *Mistura ferri aromatica, Br.*; *Mistura ferri et ammonii acetatis, U. S.*; *Mistura ferri comp., Pil. aloes et ferri, Pil. ferri iodidi, U. S., Br.*; *Pil. ferri carbon, Br.*; *Pil. ferri comp., U. S.*; *Trochisci ferri redacti, Br.*; *Troch. ferri, U. S.*

Physiological Action.—*On Animals:* Iron is an essential constituent of the animal economy, and is chiefly found in the red corpuscles of the blood, rendering them fit vehicles for carrying oxygen to every part of the economy. The animals in whose blood the proportion of iron approaches most nearly to that of man are the ox, the dog, the goose, and the hog. By experiment it has been proved that the quantity of iron in the blood, the bile, and the milk may be increased by administering various preparations of the metal with the food. Very curious conclusions have been reached by Drs. Meyer and Williams, and especially by the latter (*Archiv. f. exper. Pathol., etc.*, xiii. 70; *Boston Med. and Surg. Jour.*, Aug. 1882, p. 105)—viz.: "That iron has without doubt poisonous qualities; that the symptoms which it causes come chiefly from the alimentary canal, and that in fatal doses it diminishes the amount of carbonic acid in the blood; that the action of iron on the economy probably resembles that of arsenic and platinum; and that we are justified in believing that the action of iron on man in excessive doses would be similar to that observed in animals." It is true that the experiments which led to this judgment were performed upon frogs, rabbits, cats, and dogs, and generally by venous injections. In corroboration of their conclusions one of the authors observes: "But, more than this, it has been observed in healthy men that very large doses of iron caused weakness, a disposition to sleep, colicky pains in the region of the stomach, and vomiting;" upon which remark the commentary may be suggested that precisely such symptoms are habitually observed in healthy men who have eaten more food than they require.

On Man: In medicinal doses, varying greatly according to the preparation employed, iron does not produce any immediate effects, but after a variable interval it gives rise to a condition of plethora with characteristic phenomena. In large doses it is apt to derange the digestion, causing oppression after eating, and sometimes gastralgia and pyrosis, and, if continued, the dyspeptic derangements increase and the tongue becomes coated, while a feverish condition is induced, and constipation alternating with diarrhœa. The feces are blackened, either by the formation of salts of iron with the tannic acid of the food or by the sulphur derived from its decomposition. But preparations which are insoluble in the stomach, and the potassio-tartrate, have not this effect. A small portion only is excreted with the urine, yet enough in some instances to become a constituent of urinary calculi and also to provoke a genito-urinary irritation. Doubtless also, in appropriate morbid conditions, iron may stimulate the sexual function, as it does all others, by increasing the organic vigor. It augments the excretion of urea and raises the animal temperature. Some of the preparations are more or less irritant, especially the chlorides, the sulphates, and the iodides, and have occasioned death by their local action on the stomach—an effect due chiefly to the acid or the iodine associated with the metal. There is little doubt that the whole physiological and therapeutical action of iron depends upon its power of absorbing oxygen from the air in the lungs and carrying it to the various organs and tissues. Its proportion in the blood is therefore, other things being equal, a measure of vital activity and energy. It appears that a point of saturation may be reached beyond which the use of iron may, on the one hand, produce plethora, or, on the other, be eliminated from the economy as superfluous. But plethora, it must be remembered, is an exaggerated degree of a normal state.

It is admitted, as Hayem points out (*Bull. de thérap.*, c. 289), that the hæmoglobin of the blood carries oxygen to the tissues by means of the iron it contains. Originally, the red corpuscles are much smaller than when mature, and hence the mere enumeration of them does not represent the amount, nor even the proportion, of hæmoglobin in the blood. Their number varies with sex, age, constitution, food, the state of pregnancy, menstruation, etc. It is of singular interest that the colorless lymph and chyle are richer in hæmoglobin than the blood itself. Indeed, it would seem that the color of the red corpuscles is due to oxidation, effected chiefly, if not exclusively, in the lungs. It is also remarkable that during the administration of iron an amount of it nearly equal to

that which is taken may be recovered from the feces. Notwithstanding elaborate and long-continued experiments, the form and manner in which iron is absorbed from the alimentary canal are quite undetermined; but it is probably both absorbed and secreted by the stomach, and is eliminated by the intestinal, and indeed by all, secretions and excretions.

Hayem has insisted upon a capital point in the estimation of the red corpuscles of the blood—viz. that their number alone is not an accurate measure of the richness of the fluid, which, besides mature corpuscles, contains a large proportion of immature, or even of embryonic, cells, in which the proportion of the ferruginous element is far less than in the perfected red corpuscles, and which, if they do not receive appropriate nourishment, never reach their maturity. (Compare Willcocks, *Practitioner*, xxxi. 7, 94.) He found that a Cmm. of blood drawn from the finger of a healthy person contains about 5,000,000 red corpuscles (*Bull. de thérap.*, c. 294), and that in anæmia produced by lead-poisoning the absolute number remained about the same, though their size was altered, and they contained only half the normal proportion of hæmoglobin. The statement of Baxter and Willcocks is not in apparent accord with that of Hayem. They allege that iron first increases the number of the corpuscles, whilst their functional value remains at its original level, or may even sink below it. "The patient's symptoms are always relieved when the number of corpuscles attains its normal level, even though their individual value shows no corresponding improvement" (*Practitioner*, xxiv. 446).

Medical Uses.—Naturally, iron is indicated chiefly when the proportion of red corpuscles in the blood is permanently diminished. Their transient loss by hæmorrhage is better repaired by food, out of which the constituents of the blood are normally elaborated, supposing that the assimilative functions are not impaired. But when such impairment exists the speediest and the surest cure is brought about by the introduction of iron into the economy. By its means the proportion of red corpuscles in the blood appears to be, if it is not actually, increased, and their condition, as seen under the microscope, is changed from pale and shrivelled to red and full; through them more oxygen is introduced into the system, and a more active assimilation of nutriment, as well as a more perfect renewal of tissue, is secured. The cases in which *anæmia* may be thus remedied comprise those associated or not with chlorosis, hypochondria, convalescence from prolonged and exhausting diseases, malarial and saturnine, and some other cachexiæ attended with imperfect elaboration of the blood or its habitual waste, certain varieties of dyspepsia, some forms of albuminuria, etc. But in these and other diseases which do not involve incurable organic lesions it often happens that iron remains inoperative—in all probability because it is not digested, and not received, if at all, into the system in such a form as to make it an efficient oxygen-bearer in the blood. It has been proved that in such cases the inhalation of oxygen gas exerts a powerful although a transient stimulating influence upon the nutritive and animal functions, and that to render its action more permanent a prolonged systematic treatment by iron is essential. Conversely, it is a fact familiar to practitioners that the mere administration of iron forms but one element of the treatment in all cases of chronic anæmia. What may be accomplished medicinally by means of oxygen is more effectually and certainly attained by those various hygienic measures, including exercise, active and passive, change of scene, etc., which increase the activity of the respiratory act while stimulating the whole nervous system. Although in the greater number of *chronic nervous diseases* distinguished by morbid susceptibility the condition of the blood is impaired, and the restoration of this fluid to its normal state is an essential element of the cure, yet it often happens that the disorder is apparently limited to the nervous system, especially when the latter has been directly affected by the morbid cause. In such cases the use of iron is more prejudicial than profitable; it oppresses and does not invigorate; it impairs the appetite, constipates the bowels, and induces a dangerous plethora. Such a mode of action doubtless explains the injurious effect of iron in the greater number of cases of *epilepsy*—a disease which experience shows to be benefited, as a rule, by agents that diminish the amount of blood in the brain (vegetable diet, belladonna, bromide of potassium), and not by those which, like iron, increase it. There may be cases of the disease in which the attacks are rendered more frequent by a morbid susceptibility of the nervous system induced by sexual, and especially by unnatural sexual, excitement, and an associated anæmia; in these it is quite intelligible that iron should be salutary, especially in conjunction with appropriate hygienic measures. It was probably such cases that Gowers has reported to have been ameliorated or cured by means of iron (*Times and Gaz.*, April, 1880, p. 447). When anæmia constitutes only one out of many symptoms of a disease, the use of iron will be more or less efficient

in proportion as the anæmia depends or not upon removable causes. The anæmia of tuberculosis, of cancer, the interstitial form of Bright's disease, and some other affections is subordinate to an incurable lesion, and iron can therefore act only as a palliative. In these, and indeed in nearly all forms of anæmia, iron is food, and, like other food, must be productive of good or evil according to the patient's need of it and his power of assimilating it.

Scanty as well as excessive *menstruation* may be appropriately treated by iron, for either may be due to a deficiency of normal blood. When the catamenia are profuse but watery they are diminished by iron and the proportion of solids in the discharge is increased; on the other hand, when they are both scanty and pale iron is the best agent for increasing them. The former case is the more hopeful one, because it shows a certain energy, with a due supply of material; the latter, in its chronic type, is usually a sign of progressive and incurable exhaustion, but sometimes also it results from uterine congestion, which must first be treated before iron can be of much avail. This object is usually sought by means of aloetic purges and other stimulant and derivative agencies. In all cases of active *uterine hæmorrhage*, if there be any such independently of disease of the womb, iron should not be given internally, no matter how great may be the anæmia which excessive and repeated losses occasion; but when the flow is passive the case enters the category of passive hæmorrhages generally; and for these, whether they take place from the organ named, from the rectum, bladder, kidneys, or other part, iron becomes one of the best remedies—not, however, as iron, but in combination with a mineral acid, in which compound the astringency is derived from the acid compound rather than from the ferruginous base. The combinations of hydrochloric and of sulphuric acid with iron are in this respect the most efficient. The stimulant action of iron salts renders them less appropriate for *pulmonary* than for other internal hæmorrhages, except in the form of atomized solutions. Iron is useful in regulating the *heart* when it becomes irregular through weakness, whether or not the condition be aggravated by valvular disease. By giving tone to this, as well as to other organs, it sometimes promotes the removal of dropsies dependent upon cardiac obstruction.

Various *nervous disorders* more or less dependent upon impoverishment of the blood may be cured by iron. Of these the most directly amenable to its operation is *neuralgia*, especially of the fifth pair, and next to this of the gastric nerves, and *chorea*, which very often, like neuralgia, is the result of debility and, remotely, of impoverishment of the blood. Among other nervous affections for which iron is appropriate are various irritations of the bladder and urethra tending to occasion *retention* or *incontinence of urine*, in which the tincture of chloride or the syrup of iodide of iron may be used with much confidence in its virtues. *Seminal emissions* in weak, nervous, and excitable persons may sometimes be prevented by the same agent, especially if associated with belladonna or ergot, which, indeed, renders the cure more prompt and certain. The same is true of the use of iron in certain cases of *incontinence of urine*.

The cure of *insanity* and of *whooping cough* may be promoted by iron, like that of neuralgia and chorea, when they depend upon exhaustion of the nervous system. One of the most valuable results of recent experience in regard to insanity consists in the proof that good food and other hygienic means are essential elements in its proper treatment. In like manner, iron is not a specific for whooping cough; it only destroys the soil in which that disease tends to gain strength. Iron is contraindicated in *epilepsy*, with the proviso above mentioned; that is to say, when the patient's condition, upon other grounds, requires the use of chalybeate medicines.

Intermittent fever is cured by iron only when the disease is prolonged by exhaustion of the system and impoverishment of the blood, and this occurs especially when the sick remain in malarial localities and when an appropriate anti-periodic treatment has not been employed. Hence the use of quinine after a course of iron is found to be more efficient than before it in the cases alluded to. Enlargement of the *spleen* may be rapidly lessened by iron if the affection be not inveterate. In a word, the efficacy of iron in malarial affections is wholly subordinate to its renovating action upon the blood.

The same statement is, in the main, true respecting the use of iron in *dyspepsia*. The medicine acts chiefly by improving the blood, and thereby increasing the secretion of gastric juice and the muscular power of the stomach. But if acid preparations are used they act also as local stimulants. Hence the latter should be given immediately before meals, but other martial preparations either along with the food or directly after meals. In either case cinchona and its derivatives are important adjuvants.

The salutary action of iron in *albuminuria* probably is mainly due to its lessening the

destruction of the red blood-disks, and in a subordinate degree to its local action upon the kidneys. The latter is, however, less probable than the former, since it is alleged that the iron cannot be detected in the urine. It nevertheless lessens the proportion of albumen discharged, and in the desquamative forms of Bright's disease often effects a stable cure. This is particularly evident in albuminuria and dropsy occurring after scarlatina or from the action of cold and dampness upon the skin. But the medicine is still the best even in granular and in amyloid degeneration of the kidney. The form in which iron is administered is of secondary importance, but probably the best is a solution of muriated tincture of iron in acetate of ammonia, with an excess of acetic acid.

Iron is one of the most important aids to a proper diet in the treatment of *diabetes*; it tends to sustain the general health even when it does not directly cause a diminution in the proportion of sugar excreted. Basham's mixture (which represents the solution mentioned in the last paragraph) appears to be the best form for its administration. In chronic *mucous fluxes* of every description iron is invaluable—in those of the bowels, by its direct application partly, and in the rest by its influence upon the blood, and perhaps also by constringing the capillary vessels. It is of great value in the treatment of intestinal *worms*—not so much, probably, by directly destroying them as by rendering the intestinal secretions more healthy, and thereby depriving the parasites of their nidus. Among mucous profluvia, *chronic bronchitis* is often cured by iron, especially when the sputa are muco-purulent. Hence the reputation of the compound iron mixture as an anti- hectic medicine, and hence also the error of applying the same treatment to consumption of the lungs. True pulmonary *phthisis*, with tissue-degeneration, is benefited by iron mainly in so far as its use is proportioned to the diminished blood-formation belonging to that affection. It may be not only tolerated, but useful, while active exercise can be taken, but unless great care is exercised it increases the tendency to hæmoptysis and hastens the progress of the disease. It is most readily tolerated by the dull and lymphatic, when there is but little tendency to febrile irritation, and when the consumption is essentially chronic. As iron is a constituent of the body, and by its function in the blood one of its most important constituents, the amount of it consumed in food or medicine must bear a certain relation to the needs of the economy. It is just as possible to create a surfeit of iron as of meat and drink, of fatty food, or of cod-liver oil. Doubtless in every case there is a physical reason for the repugnance which one may acquire for certain articles of diet; and in the case of iron it is evident that if the demand for it is not sustained by such a physiological tissue-waste as exercise, etc. produce, it will more or less speedily induce an oppressive and dangerous plethora. Iron is more appropriate in *scrofula*, a disease histologically allied to, but clinically quite different from, *phthisis*; but even in this affection its value, except to meet incidental conditions, such as anæmia and dyspepsia, is not great. The iodide of iron is probably useful in glandular *scrofula* in virtue of the iodine it contains. In *syphilis* and *cancer*, for which iron has been recommended, it has no other virtues than arise from its power of sustaining the general health, or, in the case of the former disease, of mitigating the mischiefs of an excessive use of mercury.

The most efficient remedy in idiopathic *erysipelas* is the tincture of the chloride of iron given in full and repeated doses, such as from 20 to 40 drops (Gm. 1.30–2.60) every two or three hours, properly diluted. Smaller doses are quite useless. Its action is probably to constrict the capillary blood-vessels, although its acid element may directly tend to antagonize the febrile poison.

The same preparation has been reported to act very favorably in low forms of *scarlatina*, *measles*, and *puerperal fever*, but, although there is no reason to reject its use, there is not enough to recommend it. The use of iron as an internal remedy in *diphtheria* has been highly commended by several physicians, but a critical examination of their reports demonstrates that there is no more reason to attribute the measure of success they achieved to the tincture of the chloride or the subsulphate of iron they employed, the one internally and the other topically, than to the quinine and chlorate of potassium and inhalations of lime-water that were used at the same time. While there are good grounds, therefore, for using this compound treatment, there are none whatever for assigning to iron a definite share in the results obtained. The sulphuret of iron has been proposed as an antidote to constitutional *poisoning by lead* and as a means of neutralizing the salts of *mercury*, *lead*, *antimony*, *copper*, and especially *arsenic*, in the stomach. For the last named the hydrated oxide is generally employed, but, as elsewhere stated, it probably acts by mechanically enveloping the particles of arsenic rather than as a

chemical antidote. The same remark applies to the insoluble saccharated oxide of iron, and less absolutely to the hydrated oxide of iron with magnesia.

The *contraindications* to the use of iron it is essential to keep in mind. The one which surpasses all others in importance is feverishness. Almost the only exception to this statement is that tincture of chloride of iron cures *erysipelas*, but it doubtless acts, not as an hæmatic, but as a powerful astringent. In nearly all other cases fever, or even feverishness, should exclude iron, whether it be produced by chronic disease or phthisis, or by local irritations, such as *dyspepsia* with *constipation*. In this affection the complexion is often muddy and the tongue coated, not by continuous or any other "sympathy" with the gastro-intestinal disorder, but because the local affection produces general feverishness. Under such circumstances purgation is an essential preliminary to the favorable action of iron, and hence the saline chalybeate mineral waters are very efficient in curing this condition.

The local therapeutical uses of iron are numerous, but they owe their value to the astringency of the acid compounds of the metal rather than to the metal itself. Solutions and ointments of the sulphate have been applied with apparent advantage in traumatic *erysipelas*, in *phlegmasia alba*, and in various chronic eruptions of the *skin* occurring in persons in whom these affections tend to ulcerate or to persist unchanged. The subsulphate, in strong solution, has been applied to the cure of nasal, aural, and other *polypi*, and in weak solution to arrest chronic *mucous discharges* from the urethra, vagina, etc. Solution of chloride of iron represses *fungous granulations* in cases of *ingrown toe-nail*, *ulcerated gums*, etc.

Like other astringents, mineral salts of iron are used in treating varicose or simply dilated blood-vessels of the *conjunctiva* and relaxed conditions of the *funes*. Solution of chloride of iron is said to be useful as a local application in *diphtheria*, and it probably is so when the exudation is in its forming stage and of limited extent. It is worse than useless when the false membrane is extensive and thick. In the decline of the disease gargles containing a small proportion of the solution tend to constrict the part and renew its healthy action. The subsulphate has been applied in the same manner. The chlorides and the sulphates of iron are hæmostatics, and have often arrested threatening *hæmorrhage* in epistaxis, hæmorrhage from the stomach, from the extraction of teeth, leech-bites, the excision of tonsils, cancerous ulceration, and after delivery. In the last case it has been sufficiently diluted with water and carefully pumped into the uterine cavity. In pulmonary hæmorrhage an atomized weak solution (1 part of the tincture to 10 parts of water) has been inhaled with prompt effect. The injection of solutions of the lactate, the perchloride, and other salts of iron into varicose and other *aneurisms* would form an eligible method of treatment if it were not extremely dangerous. In a number of instances the operation has been speedily followed by the patient's death, either suddenly by embolism or later by ulceration.

Tannate of iron is an astringent resembling, but milder than, sulphate of iron. *Malate* of iron and its tincture are adapted to cases requiring the use of mild chalybeates, and their taste renders them suitable to children and fastidious females. They do not stain the teeth. The former is recommended to be given in doses of 4 or 5 grains (Gm. 0.20–0.30), and the latter in doses of 20 or more drops (Gm. 1.20).

In this place may perhaps be most conveniently mentioned the relative value of different preparations of iron used by subcutaneous injection. The experiments of Neuss upon this subject led him to the following conclusions: "The citro-sodic pyrophosphate of iron is superior to all other preparations of iron for this purpose. It contains 26.6 per cent. of iron, is soluble in 6 parts of distilled water, causes no annoyance, and may be detected in the urine within half an hour. Next in value comes Friedlander's albuminate, which contains less iron, however, and is more apt to undergo decomposition. After these must be ranked pyrophosphate of iron with citrate of ammonia, which, at least in one patient out of three, occasioned considerable irritation. According to these experiments, the following compounds are unfit for hypodermic use: the oxycitrate of iron, the citrate of iron and quinine, the soluble saccharate of iron oxide, and dialyzed iron (glycerinated)" (*Zeitschrift f. klin. Med.*, iii. 9).

FERRUM DIALYSATUM.—DIALYZED IRON.

Liquor ferri oxychlorati, P. G.; *Liquor ferri dialysati*.—*Liquid ferric oxychloride*, E.; *Fer dialysé*, *Solution dialytique d'hydrate de fer*, Fr.; *Flüssiges Ferroxychlorid*, *Dialysirtes Eisen*, G.

Preparation.—Dialyzed iron is made by saturating an aqueous solution of ferric

chloride with ferric hydrate, putting the liquid into a dialysator, and suspending this in water, which is often renewed—as long, indeed, as it acquires an acid reaction. Very little iron will pass through the parchment septum; when dialysis is completed the ferric solution is diluted, so that 100 grains of it, when evaporated and dried at a temperature not exceeding 100° C. (212° F.), will leave a solid residue weighing 5 grains. In France the following process has been adopted: 100 Gm. of solution of ferric chloride of 30° B. are mixed in small quantities with 35 Gm. of ammonia-water of 22° B. The precipitate dissolves at first rapidly, afterward very slowly. When the liquid has become transparent it is introduced into a dialysator and treated as stated before; 8 to 10 days are required in the preparation.

Similar solutions were obtained by Ordway (1858) and Béchamp (1859) by leaving pure ferric hydrate in contact with ferric chloride for a prolonged time. Th. Graham (1861) subjected this to dialysis, and succeeded in removing the acid until chlorine corresponding to 1.5 per cent. of HCl was left. Such a solution, however, which would correspond to $\text{Fe}_2\text{Cl}_6.95\text{Fe}_2\text{O}_3$, gelatinized ultimately. Hager (1868) found dialyzed iron to have the composition $\text{Fe}_2\text{Cl}_6.12\text{Fe}_2\text{O}_3$; Ordway's oxychloride was $\text{Fe}_2\text{Cl}_6.23\text{Fe}_2\text{O}_3$. H. Trimble (1878) has analyzed six samples met with in commerce, and found the saline portion to vary in amount between 2.51 and 4.83 per cent., and in composition between $\text{Fe}_2\text{Cl}_6.11\text{Fe}_2\text{O}_3$ and $\text{Fe}_2\text{Cl}_6.31\text{Fe}_2\text{O}_3$.

Prof. E. Scheffer (1878) showed that by precipitation with ammonia very basic oxychlorides of iron may be obtained, which, after having been thoroughly washed, will slowly dissolve in distilled water. The limits at which a soluble precipitate is obtained appear to have been reached on mixing 150 volumes of the official solution of ferric chloride with 91.5 volumes of ammonia-water. The washed precipitate contained 97.83 per cent. Fe_2O_3 to 2.17 per cent. Fe_2Cl_6 , and required over 7 weeks for effecting solution in distilled water. The preparation known in some parts of Europe as *Ferrum catalyticum* is probably made by a similar process. The German Pharmacopœia has adopted the following process: Dilute solution of ferric chloride (spec. grav. 1.281) 35 parts with water 160 parts, and pour the mixture slowly into ammonia-water 35 parts, previously diluted with water 320 parts; wash the precipitate, express, and add hydrochloric acid (spec. grav. 1.124) 3 parts; agitate occasionally for 3 days, then warm gently until solution has been effected, and dilute with water until the liquid has the spec. grav. 1.050.

On precipitating a solution of ferric chloride with an excess of ammonia the hydrate of iron invariably retains a little ammonia, and on being added to ferric chloride or to hydrochloric acid ammonium chloride is produced, which sets a limit to the solution of ferric hydrate; the basicity of such a preparation must necessarily be in an inverse ratio to the quantity of ammonium chloride contained in it, but it may be increased by subjecting it to dialysis.

The process of *dialysis* depends upon the difference in the diffusing power possessed by solid bodies when in solution. Graham (1861) ascertained that the power of diffusing

from one liquid into another is greatest in those bodies which are capable of assuming a crystalline form, and that those which are amorphous and capable of forming with water a gelatinous mass are but very slightly and slowly diffusible. He distinguished the former as *crystalloids*, and the latter as *colloids*. When both are together in aqueous solution, and separated by a septum of animal membrane or parchment-paper from water, the crystalloids only will pass through the septum, and may thus be completely separated from the colloids. The dialyzer or dialysator is conveniently made from a section of a glass cylinder or a wooden hood, or from gutta-percha or similar insoluble material. The septum is made to

cover one aperture of the short cylinder, and, after having been securely fastened, is permitted to project above. If the dialyzer is larger than about 10 or 12 inches in diameter, its sagging in the centre may be prevented by means of a net stretched over it or used for supporting it. The liquid should not be more than about $\frac{1}{2}$ inch deep upon the septum, and should never be immersed below the surface of the water in the outer vessel; on the contrary, it is best to keep the surface of the dialyzing liquid higher, so as to prevent it from becoming too dilute by the upward dialysis of water. The water in the receiving vessel should be changed daily, or, if possible, provision should be made for a continuous supply of distilled water and for the simultaneous removal of the saline solution from the bottom. The extent of surface of the septum, depth of the dialyzing

FIG. 124.

a, dialyzer; b, the same in use.

liquid, and the frequency of renewal of the water in the receiver are the main conditions which influence the success of the process. The dialysis of a solution of oxychloride of iron requires from 1 to 2 weeks, and is known to be finished when the liquid has lost its ferruginous taste and the dialysate or diffusate in the receiver shows merely traces of chlorides. The residue upon the septum is then assayed by evaporating 100 grains of it in a water-bath to complete dryness; from the weight obtained the amount of water which is necessary to bring the whole amount of the liquid to the standard of 5 per cent. is easily determined. If the process has been properly managed, evaporation will not be necessary, and should be avoided, as it interferes with the stability of the preparation.

The best material for the septum is *parchment-paper*, which is made by immersing unsized paper for a short time and at the ordinary temperature in sulphuric acid sp. grav. 1.56 to 1.60; the paper is afterward well washed with water. The parchment-paper may be folded like a filter, and this supported by a funnel, provision being made for a continuous supply of fresh water and for the removal of that which has become charged with crystalloids; or, as suggested by Klie (1878), it may be supported by a perforated funnel and thus suspended in a percolator or other suitable vessel. Huizinga (1878) prefers the parchment-paper in the form of a rectangular bag, the margins being pasted together with a solution containing 15 per cent of gelatin and 3 to 5 per cent. of potassium chromate; after exposure to the sunlight the paste is insoluble in water. Bladder may likewise be used, but is less efficient than parchment. A bladder may be completely filled with the solution of ferric oxychloride, well tied, and immersed in water; it must be strong enough to sustain a considerable amount of pressure caused by the dialysis of water into the iron solution.

Properties.—Liquid oxychloride or dialyzed iron is perfectly transparent in thin layers of a deep brown-red color, inodorous, and almost destitute of styptic taste. It is miscible with alcohol, glycerin, syrup, and distilled water, but not with spring water or other, even dilute saline, solutions. A small quantity of tannin merely darkens the liquid; a larger quantity causes a deep-brown gelatinous precipitate. A minute quantity of nitrate of silver will not disturb the liquid; a larger quantity will cause a gelatinous brown precipitate, which is again soluble in distilled water; but on adding first a slight excess of ammonia, filtering from the ferric hydrate, acidulating with nitric acid, and then testing with nitrate of silver, a white precipitate of chloride of silver is formed. "If to 1 Cem. of the liquid, diluted with 19 Cem. of distilled water, 1 drop of nitric acid be added and 2 drops of volumetric (decinormal) solution of silver nitrate, the mixture should be clear in transmitted light."—*P. G.* This test indicates the thorough washing of the ferric hydrate and the absence of ammonium chloride from the solution; a few drops more of either the acid or test solution will cause a turbidity or precipitate. Prepared by the *P. G.* process, it has the specific gravity 1.050, and contains nearly 3.5 per cent. of iron or about 7 per cent. of oxychloride, having approximately the composition $\text{Fe}_2\text{Cl}_6 \cdot 8\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. A solution which, when evaporated on a water-bath until the residue is pulverulent and weighs 5 per cent., has, according to E. B. Shuttleworth (1877), the spec. grav. 1.034. If 5 per cent. of residue is left after completely drying in a water-bath, the spec. grav. is 1.040, and if the same amount of residue is left after ignition, the spec. grav. of the solution is 1.046.

Medical Action and Uses.—The merits of dialyzed iron are claimed to be that it has no styptic taste, mixes well with water in any proportion, and does not stain the teeth or cause constipation. On pharmaceutical grounds "the action of dialyzed iron upon animal products forbids us to suppose *a priori* that it acts like other ferruginous preparations" (Depaire). A very competent judge (Bouchardat) has declared that, "theoretically, dialyzed iron must be regarded as an inert, or at best a very feeble, preparation of iron." Personne has said concerning it, "It is completely insoluble in the gastric juices. When it was injected into a dog's stomach during active digestion, and an examination was made 2 hours later, flakes of oxide of iron adhered to the undigested food, and not a trace of iron was discoverable either in the gastric liquids or on the surface of the alimentary canal. Its inactivity may be inferred from its insolubility" (*Archives gén.*, 7 sér., iv. 491). We have found it utterly to fail in cases for which iron appeared to be the proper remedy and which other preparations caused to speedily improve. Dr. R. V. Mattison has shown that dialyzed iron is probably insoluble in the gastric secretions, for he attempted unsuccessfully to dissolve the precipitate of ferric hydrate in an artificial gastric juice. Neither could he find a trace of iron in the urine of patients who were taking dialyzed iron. On the other hand, Dr. Gowers of London ascertained, by counting the red corpuscles of the blood before and after the use of the

medicine in *anæmia*, that they rose from 46 to 102 per cent. of the normal proportion in 34 days in one case, and in a second case from 26 per cent. of the normal proportion to 92 per cent. in 63 days. So Dr. Robert Amory of Boston reports that he also counted the red corpuscles in five anæmic cases treated by this preparation, and found the proportion increased in them severally as follows: No. 1, from 83 to 97 per cent.; No. 2, from 80 to 90 per cent.; No. 3, from 74 to 92 per cent.; No. 4, from 76 to 90 per cent.; and No. 5, from 76 to 83 per cent. In 1878, Dr. Da Costa used hypodermic injections of dialyzed iron in a case of *chlorotic anæmia*. 15 minims of the pure liquid were used without any unpleasant after-effects, and with a very rapid restoration of the patient to health (*Phila. Med. Times*, viii. 251). In one or two cases Dr. Lamadrid also reported the success of this treatment (*Med. Record*, xiv. 17). In 1879, Luten stated that 25 or 30 drops of the solution may be injected without producing the slightest disturbance; that it causes a diffusive sense of warmth, a determination of blood to the face, a sort of intoxication, in fine; and he compared its effects to those of transfusion of blood (*Mouvement Méd.*, Juin, 1879). In 1881, Neuss classed this preparation of iron among those unsuited to hypodermic use (*Zeitsch. f. klin. Med.*, iii. 9), and Kemp found alarming symptoms immediately following its use, and the subsequent formation of abscess at the point of puncture (*Med. Record*, xiii. 481). We cannot learn that any later experience has confirmed the very favorable judgment originally expressed of the hypodermic use of dialyzed iron. The observations on which that judgment rests would be conclusive of the hamatogenous virtues of dialyzed iron had we not the positive declaration of Hayem, who pursued the very same method of investigation (see FERRUM), that, at least in saturnine anæmia, "iron does not influence the number, but only the development, of the red corpuscles." But in Dr. Prosser James's opinion, "The testimony of physicians to the activity of dialyzed iron is so abundant that it is unnecessary to add to it" (*Times and Gaz.*, Dec. 1882, p. 659). In relation to the value of iron employed hypodermically, it may be added that Glaevecque found the citrate of iron very efficient in *anæmia* when used in this manner in the dose of 2 grains (Gm. 0.10) (*Archiv. f. exper. Pathol.*, etc., xvii. 466).

Numerous cases have been published which appear to prove that dialyzed iron is an efficient antidote to the poisonous action of *arsenic* in the stomach. Dr. Mattison, having performed some experiments to determine the conditions of its efficacy, found—1, that a solution of dialyzed iron to be of value as an arsenical antidote must be precipitated by the action of some neutral or alkaline salt; 2, that such precipitation, and the consequent production of ferric hydrate, are accomplished when this preparation is taken into the stomach; and 3, that, therefore, the solution of dialyzed iron is a valuable antidote in arsenical poisoning; 4, that to ensure the formation from it of ferric hydrate its administration should be followed by that of a teaspoonful of common salt.

Dialyzed iron may be given internally in doses of from 5 to 30 or more drops (Gm. 0.30–2.0) several times a day, simply diluted with water or in some sweetened and aromatic vehicle.

FERRUM REDUCTUM, U. S., P. G.—REDUCED IRON.

Ferrum redactum, Br.; *Ferrum hydrogenio reductum*, *Ferrum ope hydrogenii paratum*.—*Iron reduced by hydrogen*, *Iron by hydrogen*, E.; *Fer réduit par l'hydrogène*, Fr.; *Reducirt Eisen*, G.

Preparation.—Take of Hydrated Peroxide of Iron 1 ounce; Zinc, granulated, a sufficiency; Sulphuric Acid a sufficiency; Chloride of Calcium a sufficiency. Introduce the hydrated peroxide of iron into a gun-barrel, confining it to the middle part of the tube by plugs of asbestos. Pass the gun-barrel through a furnace, and when it has been raised to a strong red heat cause it to be traversed by a stream of hydrogen gas developed by the action on the zinc of some of the sulphuric acid diluted with eight times its volume of water. The gas before entering the gun-barrel must be rendered quite dry by being made to pass first through the remainder of the sulphuric acid, and then through a tube 18 inches long packed with small fragments of the chloride of calcium. The farther end of the gun-barrel is to be connected by a cork with a bent tube dipping under water, and when the hydrogen is observed to pass through the water at the same rate that it bubbles through the sulphuric acid the furnace is to be allowed to cool down to the temperature of the atmosphere, the current of hydrogen being still continued. The reduced iron is then to be withdrawn and enclosed in a dry, stoppered bottle.—Br.

In all essential details this process is identical with the one of the U. S. P. 1870, which

was elaborated by Prof. Procter. The drying of the hydrogen is unnecessary, but provision must be made to prevent the acid liquid in which hydrogen is generated from being mechanically carried over; this is effected by passing the gas through an empty vessel before it enters the reduction-tube, or through basic acetate of lead, which will retain also gaseous impurities with which the hydrogen may be contaminated from impurities of the zinc or acid. The reduction-tube, we think, should be filled with hydrogen gas before it is heated to redness, and the heat is best kept at dull redness, so as to obtain the metal in a finely-divided state, and not more or less granular, which would result from carrying on the operation at a bright-red heat. At the high temperature the ferric hydrate is converted into ferric oxide, and this is decomposed by the hydrogen, with the liberation of iron and the production of water; $\text{Fe}_2\text{O}_3 + 3\text{H}_2$ yields $\text{Fe}_2 + 3\text{H}_2\text{O}$. That the reduction has been completed is ascertained from the absence of aqueous vapor in the bubbles breaking through the water, or from the uniform rapidity with which the bubbles pass both through the water and through the liquid placed between the generator and reduction-tube. After the fire is withdrawn the reduced iron would burn again to ferric oxide if it were allowed to come into contact with oxygen while warm; the hydrogen must therefore be continually passed through the reduction-tube until the temperature has been lowered to that of the surrounding atmosphere. Using 2 pounds of ferric hydrate, the process occupies from 5 to 8 hours. It is scarcely necessary to state that the ferric hydrate should have been well washed.

Various other methods have been suggested for obtaining reduced iron, but they do not appear to be used on a large scale. For reduction in a current of hydrogen Peligot (1844) proposed ferrous chloride, and Wochler (1855) ferrous oxalate, or an oxide obtained by strongly heating a mixture of ferrous sulphate and sodium chloride and washing out the soluble salt. A. Morgan (1854) recommended the calcination of a mixture of ferric oxide, potassium ferro cyanide, and potassium carbonate, each previously deprived of water. Zaengerle (1857) used ferrous oxalate instead of ferric oxide. After cooling, the mass requires to be well washed and dried. The metallic iron reduced by electricity from ferrous sulphate (Boettger, 1846), or from ferrous chloride (Collas), has no advantage over that prepared with hydrogen.

Properties.—Reduced iron is a very fine gray (grayish-black, *U. S., Br.*) powder, free from metallic lustre, but exhibiting metallic streaks when rubbed with firm pressure in a mortar, and yielding a lustrous scale when struck on an anvil with a hammer. It is without odor or taste, and is not altered in dry air, but is gradually oxidized and becomes rust-colored in a damp atmosphere, and when touched with a lighted taper ignites and burns slowly to ferric oxide. It is strongly attracted by the magnet, and is insoluble in all simple solvents, but is wholly dissolved by dilute hydrochloric or sulphuric acid, with the evolution of hydrogen, the solution showing the reactions of ferrous salts.

Tests.—The hydrogen evolved on dissolving reduced iron in diluted hydrochloric acid should not at once impart to paper moistened with solution of silver nitrate a yellow or brown color (absence of arsenic and sulphur); the undissolved residue should not weigh more than 1 per cent. (carbon). *P. G.* The hydrogen should be free from noxious odor, and should not impart a black color to filtering-paper moistened with solution of lead acetate and stretched over the orifice of the test-tube; the black color would be due to the presence of sulphur, resulting from the sulphate which remains in incompletely-washed ferric hydrate. The solution in hydrochloric acid should not assume a red color when tested with sulphocyanide of potassium (absence of ferric or magnetic oxide). The presence of magnetic oxide is also indicated by the black instead of gray color of the powder. Treated with iodine or bromine, dissolved in solution of potassium iodide or bromide, the black oxide remains behind, and its weight should not exceed 50 per cent.; this residue should be completely soluble in hydrochloric acid.—*Br.* "If 1 Gm. of reduced iron be digested with 3.5 Gm. of iodine, 2.5 Gm. of iodide of potassium, and 50 Ccm. of distilled water for 2 hours, the resulting filtrate should have a green color, and should not be rendered blue by gelatinized starch (presence of at least 80 per cent. of metallic iron)."—*U. S.* If 0.3 Gm. of reduced iron be digested for 1 hour in a water-bath in a closed bottle with 50 Gm. of test solution of mercuric chloride, the liquid afterward diluted to 100 Ccm., and set aside until clear, 25 Ccm. of the liquid should require for oxidation not less than 38 Ccm. of volumetric solution of potassium permanganate (presence of at least 89.75 per cent. of metallic iron).—*P. G.* The metallic iron is dissolved as ferrous chloride, while a reduction of mercuric to mercurous chloride, and partly to mercury, takes place.

Mr. Creuse (*Proc. Amer. Phar. Assoc.*, 1874, p. 435) suggested to determine the

amount of pure iron from the measure of the hydrogen given off; the presence of oxides, however, appears to interfere with the correctness of the results. Schacht (1877) regards the following as sufficient evidence of purity: It is "a very fine gray powder without gloss; when heated in the air it burns to ferric oxide. It is completely soluble in warm diluted pure hydrochloric acid, with the evolution of hydrogen, which is indifferent to lead-paper. When treated for half an hour, at the ordinary temperature and with occasional agitation, with twenty-five times its weight of solution of ferric chloride sp. gr. 1.30, it is completely dissolved."

FERRUM PULVERATUM, S. ALCOHOLISATUM, S. PORPHYRISATUM, P. G., or *pulverized iron*, may be mistaken for reduced iron. It is made in Europe on a large scale from a good quality of cast iron, and therefore contains carbon. It has the general properties of reduced iron, from which it differs in being denser, having a distinct metallic lustre, and in not igniting when touched with a lighted taper; the hydrogen evolved by it has a distinct odor, but should contain traces only of sulphuretted hydrogen. The solution of iron in hydrochloric acid should not yield a dark color or precipitate with sulphuretted hydrogen (absence of lead, copper, etc.), and when oxidized with nitric acid and treated with ammonia in excess the filtrate should be colorless (copper, etc.), and not be rendered turbid by hydrosulphate of ammonium. A freshly-prepared solution of 0.1 Gm. of the powder in 15 Gm. of diluted sulphuric acid should require for complete oxidation not less than 55.5 Ccm. of the volumetric solution of potassium permanganate.—*P. G.*

Off. Prep.—*Pil. ferri iodidi, U. S.*

Medical Action and Uses.—This preparation was originally proposed as a substitute for subcarbonate of iron. It was less bulky, and therefore more likely to agree with the stomach; but not improbably there happened in this case what has often been observed when the nutritious elements of food are substituted for those forms of it which Nature has provided. In point of fact, it is even more likely to derange the stomach than the preparation mentioned, partly on account of the impurities it sometimes contains to the extent of 50 per cent., and partly because it is very apt to cause the formation in the stomach, and the eructation, of sulphuretted hydrogen. Moreover, when given in pills and pastilles they often escape the solvent power of the digestive juices, and are evacuated in the same form in which they were swallowed. The only way in which it can be administered with an assurance of its solution and absorption is to give it at meal-times or immediately afterward in a wafer or suspended in a little water. It may be prescribed in the *dose* of from 1 to 5 grains (Gm. 0.05–0.30).

FICUS, *U. S., Br.*—**FIG.**

Caricæ; *Ficus passa, Fici, Fructus caricæ.*—*Figue, Fr.; Feige, G.*

The fleshy receptacle, bearing fruits upon its inner surface, of *Ficus Carica, Linné*. Steph. and Church, *Med. Bot.*, plate 154; Bentley and Trimen, *Med. Plants*, 228.

FIG. 125.

Ficus carica, Linné: a, section of fig; b, staminate flower; c, pistillate flower.

Nat. Ord.—Urticacæ, Artocarpeæ.

Origin.—The fig tree is indigenous to Western Asia, from Asia Minor and Syria eastward to Lake Aral, and has been under cultivation from a very remote period. At present it is cultivated in most countries of the Old and New Worlds which lie in the warmer temperate regions, in many of which it is also found wild. It attains a height of about 25 feet (7.5 M.), is irregularly branched, has rough palmately-lobed, irregularly-toothed subcordate leaves, in the axils of which appear the fleshy hollow receptacles, upon the inner surface of which the minute flowers are situated, the few staminate flowers being placed near the mouth.

Description.—The receptacle, erroneously called fruit, is pear-shaped, short-stalked, or with a circular stalk-scar at the base, and about 3 inches (75 Mm.) long; in the green state it contains a milky, acid juice, which changes to saccharine, the color of the receptacle becoming yellowish and purplish. The orifice is surrounded by several

fleshy scales, and the greater portion of the inner surface is covered in the ripe fig by numerous small yellowish akenes, popularly called seeds. Figs have a peculiar fruity odor and a very sweet somewhat mucilaginous taste. A warm and dry climate is best adapted for growing figs with the view of preserving them in the dry state.

They are dried either by artificial heat or by exposure to the sun, and packed in this condition (*natural figs*), or they are rendered pliant by kneading and squeezing, and then packed and pressed into boxes (*pulled figs*). In the latter condition they are always of a very irregular shape, yellowish, somewhat translucent, and covered with effloresced sugar. The large pulpy figs are known as *Turkey* or *Smyrna figs*, the small and dried ones as *Greek figs*. In Italy the early figs which appear in the axils of the previous year's leaf-scars are known as *grossi* and *orni*, while those produced in the axils of leaves are known as *foriti* or as *cratiri*, the latter name being given to those which ripen after the fall of the leaves.

Constituents.—Exclusive of the akenes, which, together with the cellular tissue, Bley (1831) found to constitute about 15 per cent. of the weight of figs, he obtained 16 per cent. of water, 62.5 per cent. of sugar (glucose), the remainder being gum, fat, and saline constituents.

Off. Prep.—Conf. sennæ, *U. S.*, *Br.*

Allied Plants.—*BROSIMUM ALICASTRUM*, Swartz. This large tree bears a globular fruit of the size of a nutmeg, imbedded in the receptacle. The seeds are known in Jamaica as *bread-nuts*, and have a taste resembling that of chestnuts. The milk-juice of old branches is acrid.

BROSIMUM GALACTODENDRON, Don, s. *Galactodendron utile*, Kunth, is the *cow tree*, *palo de vaca*, or *palo de leche*, of tropical America. On making incisions into the bark it yields a milk-juice which resembles, and is used like, cow's milk; this contains, according to Boussingault, 58 per cent. of water and 42 per cent. of fixed matter, the latter consisting of wax and fat 32.2, sugar 2.8, proteids 1.7, salts 0.5, and undetermined substances 1.8 parts.

ARTOCARPUS INCISA, Linné, is indigenous to the Moluccas and the islands of the Southern Pacific. The nearly-ripe pistillate inflorescence, known as *bread-fruit*, forms a globular sorosis about 6 inches (15 Cm.) in diameter, and consists of a mealy and spongy receptacle in which the oblong angular akenes are imbedded. A similar product, known as *jack-fruit*, is yielded by *Artocarpus integrifolia*, Linné; it is nearly pear-shaped, and is largely used in India and the East Indian islands.

Medical Uses.—The saccharine and mucilaginous constituents of figs render them nutritive, and in their fresh state laxative. The latter operation of dried figs is mainly due to the indigestibility of their seeds and tough skins, which also tend to occasion flatulence. They form an agreeable addition to the various pisans employed in *catarrhal affections* of the air-passages and other mucous canals, and roasted figs have from time immemorial formed convenient cataplasms for *gum-boils*, *abscesses* of the *anus*, *vulva*, etc. It is stated by Billroth that poultices made with dried figs and milk neutralized the *fetor* of cancerous and other ulcers which resisted all the usual deodorizers (*Med. Record*, xix. 308).

FENICULUM, *U. S.*—FENNEL.

Feniculi fructus, Br.; *Fructus feniculi*, P. G.; *Semen feniculi*.—Fennel-fruit, *Fennel-seed*, E.; Fruits (Semences) de fenouil, Fr.; Fenchel, G.

The fruit of *Feniculum vulgare*, Gaertner (s. *F. officinale*, Allioni, s. *F. capillaceum*, Gilbert, s. *Anethum* (Meun, Sprengel) *Feniculum*, Linné). Bentley and Trimen, *Med. Plants*, 123.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—The fennel is indigenous to Southern Europe, and is frequently found wild in Western and South-eastern Europe and in Western Asia. Commerce is mainly supplied with the fruit from Germany and France, where the plant is extensively cultivated. It is an herbaceous annual or perennial, varying in cultivation considerably in size and in its fruit. The stem is 3 to 6 feet (0.9–1.8 M.) high, somewhat furrowed, green, and glaucous; the leaves are decomposed or twice-pinnate, with the pinnae very narrow; the umbels are at the top of the stem or branches, compound, large, and without involucre or involucl. All parts have an agreeable aromatic odor and a sweetish-aromatic taste. A little less than 250,000 pounds of fennel, fenugreek, and cummin are annually imported into the United States.

Description.—FENNEL-FRUIT is about $\frac{1}{6}$ to $\frac{1}{3}$ inch (4–8 Mm.) long, oblong in shape, nearly cylindrical, and readily splitting at maturity into the two mericarps, which often become somewhat curved. The face is broad and

FIG. 126.
Feniculum: fruit, 3 diameters; transverse section, 8 diameters.

flat, the back rounded, and has five prominent obtuse ribs of a light-brown color, the intervening furrows being almost blackish-brown. There are usually six oil-tubes, one under each furrow, and two, or in some varieties two pairs, on the face. The odor and taste of fennel are agreeably sweetish-aromatic and anise-like.

The commercial varieties are *Saxon* or *German fennel*, which is about $\frac{1}{4}$ inch (6 Mm.) long and of a brownish tint; and *Roman fennel*, which is nearly twice as large, mostly strongly curved, of a distinct greenish tint, with broader and rather sharper ribs, and of a stronger and more pleasant odor. The latter is often referred to *Fæn. dulce*, *De Candolle*, but appears to be merely a variety of *F. vulgare*, produced by cultivation.

FENNEL-ROOT is somewhat employed in Europe. It is 6 to 10 inches (15 to 25 Cm.) long, above nearly an inch (25 Mm.) thick, several-headed, cylindrical, little-branched, but beset with numerous thin and wrinkled radicles. The root is externally light-brown, annulate, and longitudinally wrinkled, internally white; the bark thick, fleshy, with several circles of brown resin-cells, and the medullium yellowish and radially striate. It has an aromatic odor and a sweet fennel-like taste.

Constituents.—Fennel contains about 12.5 per cent. of fixed oil, some sugar, and from 2 to 4 per cent. of volatile oil, to which the sweet taste of the fruit is chiefly due. (See OLEUM FÆNICULI.) The root contains a small quantity of volatile oil, more sugar, and considerable starch.

Pharmaceutical Uses.—**SYRUPUS FÆNICULI.**—Syrup of fennel, *E.*—Digest for 3 hours 2 parts of bruised fennel with 12 parts of hot water in a closed vessel, and dissolve in 10 parts of the infusion 18 parts of sugar.—*P. G.* 1872.

Off. Prep.—*Aqua fœniculi*, *Br.*; *Infus. sennæ comp.*, *U. S.*

Medical Action and Uses.—Employed by the ancients as a carminative and digestive stimulant and to promote the secretions, it continues to be used for like purposes at the present day. It is still alleged to increase the secretion of milk, urine, perspiration, and mucus, and to be an active emmenagogue. It is most commonly used as an ingredient in carminative compounds or as a simple infusion for the relief of *nausea* and of *colic*. It is very appropriate in hot infusion, as an adjuvant, in the treatment of *amenorrhœa* from uterine congestion and for re-establishing the *lactal secretion* when suppressed. An infusion of fennel may be made with 60 grains (Gm. 4) of the bruised seed in half a pint (Gm. 250) of boiling water. Of this a teaspoonful may be given at short intervals to an infant and a wine-glassful to an adult.

FÆNUM GRÆCUM.—FENUGREEK.

Semen fœnugræci, *P. G.*; *Fenugrec*, *Sénégrain*, *Fr.*; *Bockshornsamen*, *G.*

The seeds of *Trigonella Fænum græcum*, *Linneé*. Bentley and Trimen, *Med. Plants*, 71.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—Fenugreek is an annual herb indigenous to Western Asia and naturalized in India, Eastern and Northern Africa, and Southern Europe; it is extensively cultivated in Asia and Africa. The plant is about a foot (30 Cm.) high, nearly simple, has trifoliate leaves with articulated obovate or wedge-oblong denticulate leaflets, solitary sessile pale-yellowish flowers, and produces linear-curved compressed legumes with a slender beak and containing about sixteen seeds.

Description.—The seeds are $\frac{1}{8}$ inch (3 Mm.) long and broad, $\frac{1}{12}$ inch (2 Mm.) thick, of an oblique rhombic shape, flattened, pale brownish-yellow, on both flat surfaces with a deep groove extending in a diagonal direction, very hard, of a strong, unpleasantly aromatic odor, suggesting that of melilot, and a mucilaginous and bitterish taste. The thin hard testa encloses a yellowish embryo having a thick radicle, which is strongly bent upon the edges of the cotyledons and has its position externally indicated by the grooves. The embryo is surrounded by a colorless hornlike tissue, which is regarded as the inner seed-coat or by some authors as a thin layer of albumen.

Constituents.—Fenugreek was examined by Bassou, who ascertained the presence of volatile and fixed oil, mucilage, and a bitter principle which was not obtained pure. The mucilage is contained in the integuments of the seeds, and amounts to about 28 per cent.; the fixed oil, about 6 per cent., resides in the embryo. Jahns obtained 3.4 per cent. of nitrogen, which would indicate 22 per cent. of albumen. A small amount of tannin is present in the testa, but no starch.

Adulterations.—Being usually kept in the ground condition, fenugreek is liable to be adulterated with farinaceous substances, in which case it will acquire a blue color on the addition of iodine.

Allied Plants.—The seeds of other species of *Trigonella* have similar properties, but are much smaller.

Medical Action and Uses.—*Fœnum græcum* is one of those simple medicines which figured largely in the materia medica of the Greeks and their successors, and which possessed hardly any other than emollient virtues. Like flaxseed, marshmallow, and slippery elm, it was used to prepare cataplasms for inflamed parts and soothing pessaries for the uterus and vagina; its decoction was similarly employed, and injected into the rectum, and formed a ptilisan for affections of the throat and air-passages. Its oil, like linseed and olive oil, was applied to burns, excoriations, etc. It may be used in a decoction prepared with an ounce of the seed to a pint of water (Gm. 30 to Gm. 500). Poultices may be made of the ground seeds.

FRANGULA, U. S.—FRANGULA.

Cortex frangulae, P. G.—*Alder buckthorn*, E.; *Écorce de Bourdaine*, *Bourgène*, Fr.; *Faulbaumrinde*, G.

The bark of *Rhamnus Frangula*, *Linneé*, s. *Frangula vulgaris*, *Reichenbach*, s. *Frangula Alnus*, *Miller*, collected at least one year before being used. Bentley and Trimen, *Med. Plants*, 65.

Nat. Ord.—*Rhamnaceæ*.

Origin.—The alder buckthorn is a shrub about 10 to 15 feet (3 to 4.5 M.) high, which grows in wet places from the northern coast of Africa throughout Europe, and extending eastward into Siberia. It has alternate elliptic, oval, or obovate entire leaves, which are obtuse or slightly pointed at the apex; greenish hermaphrodite flowers in axillary-clusters of three or five, and red, finally black, berries of the size of a pea and containing two or three roundish-angular seeds. The bark is collected in the spring from the younger trunks and large branches. The Norwegian and the United States Pharmacopœias require it to be used not sooner than a year after it has been collected. The shrub is also known in different parts of Europe as *black alder*, *aune noir*, and *Schwarzerle*, which names are perhaps more properly restricted to species of *Alnus* (see page 155).

Description.—*Frangula-bark* is in small quills about $\frac{1}{25}$ or $\frac{1}{16}$ inch (1 or 1.5 Mm.) thick, externally gray or grayish-brown, or from the younger branches blackish-brown, marked with numerous small, whitish, transversely-elongated suberous warts; the inner surface is smooth, orange-yellow or brownish-yellow. When fresh it has a disagreeable odor and taste, but in the dried state it has scarcely any odor, a sweet and bitterish taste, and breaks in the inner layer with a fibrous fracture, showing the yellow bast-fibres, a greenish middle layer, and a purplish-colored corky layer. When moistened with lime-water it acquires a red color. With cold water it yields a yellow, and with hot water a brown, infusion, which is colored dark-brown, but not precipitated, by ferric chloride.

Constituents.—The bark was analyzed by Gerber (1828), Binswanger (1849), L. A. Buchner (1853), Casselmann (1857), Phipson (1859), and others. The constituent which possesses most interest is *frangulin* or *rhamnaxanthin*, $C_{20}H_{20}O_{10}$, which is extracted from the bark by carbon bisulphide and obtained pure by recrystallization from alcohol and ether. It is a lemon-yellow crystalline mass of a slightly silky lustre, without odor and taste: by sublimation it is obtained in yellow needles. It is insoluble in water, slightly soluble in cold alcohol and ether, and freely soluble in alkalies, with a bright-purple color. It dyes silk, wool, and cotton, and is resolved by acids into sugar and frangulic acid, $C_{14}H_{10}O_5$. The bark contains also a yellow resinous principle, tannin, an amorphous bitter principle which appears to have a purgative action, and various ordinary principles. It yields 5 or 6 per cent. of ash. The odor of the fresh bark is due to a volatile principle which has not been isolated. Liebermann and Waldstein (1876) obtained *emodin*, $C_{15}H_{10}O_5$,

FIG. 127.

Frangula-bark: transverse section, magnified 80 diameters.

from old frangula-bark, by boiling with diluted sulphuric acid those constituents which are soluble in soda and are reprecipitated from this solution by hydrochloric acid. Kubly's *avornin* was impure frangulin.

Off. Prep.—*Extract. frangulæ fluidum, U. S.*

Allied Plants.—*RHAMNUS PURSHIANA*, *De Candolle*, is found on the west coast of North America from the British possessions southward to California. It is a shrub or small tree, attaining a height of 15 to 20 feet (4.5 to 6 M.); has elliptic, mostly acute, at the base obtuse, denticulate, and somewhat pubescent leaves, rather large flowers in umbellate cymes, and broadly obovoid, three-lobed and three-seeded, black, baccate drupes. Like the next, it belongs to the sub-genus *Frangula*. The bark is known on the Pacific coast as *chitten-bark*, and has been introduced under the name of *cascara sagrada*, or *sacred bark*. It is met with in curved pieces or quills varying in size, externally smooth or nearly so, gray, sometimes with whitish patches, after the removal of the external layer brown or reddish-brown, the inner surface smooth and yellowish, and upon the transverse section radially striate and yellowish. It breaks with a nearly smooth fracture, is colored red by potassa, and has little odor and a bitterish taste. Prof. Prescott (1879) determined in it the presence of red resin colored brown by potassa; a resinous body not colored by potassa, but red-brown by sulphuric acid; a white sublimable crystalline compound; a brown resin colored purple-red by potassa; tannin, oxalic acid, malic acid, and other common vegetable principles.

RHAMNUS (FRANGULA, Gray) CALIFORNICA, *Eschscholtz*, is somewhat smaller than the preceding, has ovate-oblong or elliptical denticulate or nearly entire leaves, produces numerous, mostly abortive flowers, and has a blackish-purple two- or three-seeded fruit. It grows throughout California, and a variety with white tomentose leaves extends through Arizona to New Mexico.

RHAMNUS (FRANGULA, Gray) CAROLINIANA, *Walter (Southern buckthorn)*, is a shrub or small tree growing in moist localities in the southern part of the United States, northward to Southern New York, and westward to Texas and the Rocky Mountains. It has oblong serrulate leaves, short-peduncled flowers, and purplish globose three-seeded fruits. The bark has been recently recommended as a substitute for the European frangula-bark.

Medical Action and Uses.—The fresh bark excites nausea, colic, vomiting, and violent purging, but by drying it loses in some degree its acrid qualities, and is then used in Germany as a domestic purgative. It gives a deep-yellow color to the feces and urine. It is stated to be employed as a substitute for rhubarb, but its action is much harsher, and indeed it may be ranked among the drastic cathartics. A decoction of it is sometimes used in *dropsy*, and the same preparation, as well as an ointment prepared with the fresh bark, is employed in treating the *itch*. The decoction may be prepared with half an ounce of the bark and half a pint of water (Gm. 15 to Gm. 250), and given in tablespoonful doses.

Rhamnus Purshiana is described as a mild laxative by Wolff, Stieren, Carter, and others. The fluid extract is usually employed as a purgative in the dose of a teaspoonful diluted with syrup, but some recommend it as a laxative in *doses* of 20 drops three times a day. Like several other purgatives, its action is not diminished, but increased rather, by repetition.

FRASERA.—AMERICAN CALUMBA OR COLOMBO.

Radix fraseræ, Radix colombo americana.—*Racine de colombo de Mariette (d'Amérique)*, Fr.; *Fraserawurzel, Amerikanische Colombowurzel*, G.

The root of *Fraseria Walteri*, *Michaux* (Fr. *caroliniensis*, *Walter*).

Nat. Ord.—Gentianaceæ.

Origin.—This is a tall biennial or triennial herbaceous plant indigenous to the United States, where it grows in rich and moist soil west of the Alleghany Mountains from New York southward, and in the Southern States. The plant is smooth, 5 to 10 feet (1.5 to 3 M.) high; the leaves are in whorls of about six, sessile, entire, oblong, and parallel-veined. The yellowish-white flowers form a large pyramidal panicle and bear a large roundish gland in the middle of each corolla-lobe; the fruit is a flattened capsule containing several seeds. The root should be collected in the autumn of the second year.

Description.—In general aspect American colombo resembles gentian-root, except that it is of a lighter and more distinctly yellow color internally and of a light orange-brown externally. When dried in transverse slices the outer layer of the bark projects above the shrunken tissue of the fleshy central portion, and this with the yellow tint gives it a faint resemblance to colombo, from which it is easily distinguished by the absence of the projecting vascular bundles in the interior and of the radiating zone near the cambium. It is now generally dried in longitudinal slices, the bark overlapping. The tissue upon transverse section is pretty uniform in appearance, the wood-bundles

being nearly imperceptible in the fleshy parenchyma; the rather thick bark shows two different colored layers, and a dark-brown cambium-line separates it from the medullum. When dry it has a slight odor; the odor of the infusion is similar to that of gentian; its taste is sweet and bitter and free from astringency.

Constituents.—*Frasera*-root was analyzed by J. W. Douglass (1840), W. R. Higginbotham (1857), and F. W. Thomas (1868), who proved the absence of starch and the presence of pectinaceous and saccharine compounds in it. Douglass noticed the dark coloration produced in the infusion by ferric salts, and attributed it to tannin. G. W. Kennedy (1873) obtained from the root *gentisic acid* and *gentiopierin*. Prof. J. U. Lloyd (1880) obtained the coloring matter in tufts of lemon-yellow silky needles which are insoluble in cold water and cold alcohol, but dissolve freely in ether, chloroform, carbon disulphide, and boiling alcohol, and are soluble in nitric acid with a deep-red, and in sulphuric acid with a deep orange-red, color. Prof. Patch (*Proc. Amer. Phar. Assoc.*, 1881, p. 467) pointed out that the principle differs from gentisic acid of gentian in being less soluble in cold alcohol, more soluble in hot alcohol and in ether, in having a lower melting-point (187° F.), and in showing a different behavior with nitric and sulphuric acids. American Colombo is therefore closely analogous to gentian, from which it appears to differ, chemically, in containing less of the bitter principle than the latter, and a larger proportion of a yellow coloring matter distinct from that of gentian, though resembling the latter in the brown color produced with ferric salts.

Medical Action and Uses.—When fresh it is said to have emetic and purgative properties, and has been compared in its action to rhubarb. The dried root is reputed to have the tonic properties of simple bitters, and may be given in an infusion made with an ounce of the root to a pint of boiling water. *Dose*, 1 to 2 fluidounces (Gm. 30–60).

FRAXINUS.—ASH.

Frêne, Fr.; *Esche*, G.

Nat. Ord.—Oleaceæ, Fraxineæ.

Description.—FRAXINUS EXCELSIOR, *Linné*, the European ash, which is sometimes cultivated in the United States as a shade tree, attains a height of 100 to 150 feet (30 to 45 M.), has a straight trunk, a tough, whitish, elastic wood, which is difficult to split and very durable, and lax racemes of polygamous flowers without calyx or corolla. The bark, which is collected from the branches in spring, is in quills having a gray or greenish-gray color externally, numerous small gray or brownish-white suberous warts, and a smooth inner surface of a yellowish or yellowish-brown color. It is inodorous, has a bitter, astringent taste, and breaks with a smooth and, in the inner layer, fibrous fracture. The leaves are pinnate, composed of eleven or thirteen nearly sessile leaflets, which are almost smooth, about 2 inches (5 Cm.) long, vary in shape between elliptic-oblong and oblong-lanceolate, have a wedge-shaped and entire base, and are sharply serrate above; in some varieties the leaves have a crisp margin or a whitish or variegated color. The fruit is a linear-oblong samara about 1½ inches (37 Mm.) long and ¼ inch (6 Mm.) broad, brownish, round at the base, at the apex extended into a long many-nerved somewhat oblique wing, and contains a single pendulous seed having an astringent, bitter and acrid taste.

FRAXINUS AMERICANA, *Linné*, s. FR. ALBA, *Marsh*, s. FR. EPIPTERA, *Michaux*, the North American white ash, is a handsome forest tree growing from Nova Scotia southward to the Mexican Gulf and westward to Lake Superior and Eastern Kansas. It attains a height of 60 to 80 feet (18 to 24 M.), has a durable, tough wood, seven or nine ovate-oblong, acuminate leaflets, and a terete fruit extended above into a spatulate-linear wing. The bark, which has been employed, is collected from the trunk and the root, the latter being preferred. It is ¼ to ½ inch (3 to 6 Mm.) in thickness, usually freed from the corky layer, whitish or yellowish, sometimes brownish, frequently with ridges of a warty cork adhering, and upon the inner surface yellowish and smooth; it breaks with a very fibrous fracture, and has a slight aromatic odor and a bitter and somewhat acrid taste.

Constituents.—The European ash contains in the bark tannin, the bitter glucoside *fraxin* (see HIPPOCASTANUM), and a crystalline principle obtained by Keller by a process similar to that by which salicin may be obtained: it was at first named *fraxinin*, but was recognized as mannit by Stenhouse and Rochleder. Garot (1853) found in the leaves malate of calcium; and in addition to this Gintl and Reinitzer (1882) obtained free malic acid, tannin, mannit, inosit, a little quercitrin, glucose, gum, and a volatile oil of

the formula $C_{10}H_{20}O_2$. Mouchon's *fraxinit* is extract-like and said to be purgative. The fruit contains, according to Keller, a green oil of a disagreeable odor, an acrid resin, a bitter principle, tannin, and mucilaginous matter.

The *white-ash bark*, examined by Howard M. Edwards (1882), contains a mild aromatic volatile oil, an alkaloid which has not been investigated, resin, starch, sugar, and coloring matter producing a blue-black color with ferric chloride. J. M. Bradford (1882) believes that tannin is also present.

Pharmaceutical Uses.—EXTRACTUM FRAXINI AMERICANÆ. Made with alcohol, the yield is about 22 per cent.; with weaker alcohol 30 to 32 per cent. of extract may be obtained.

EXTRACTUM FRAXINI AMERICANÆ FLUIDUM. Edwards proposed as the menstruum alcohol containing 20 per cent. of glycerin; it is of a blackish-red color.

VINUM FRAXINI AMERICANÆ has been made by T. S. Wiegand (1882) with sherry wine, and represents 4 troyounces of the bark in the pint.

Medical Action and Uses.—No accurate description of the operation of this medicine has been published. Infusions of the leaves are said to be either diaphoretic or diuretic. The bark at one time enjoyed a certain vogue in Europe as a remedy for *intermittent fever*, and there seems to be no doubt that it was often used with success in cases which had proved rebellious to cinchona, so that it may be included in the large class of succedanea for Peruvian bark and its derivatives. The leaves are more or less purgative, and are said to operate like senna, but their more important use appears to have been in the treatment of *gout*. There seems to be conclusive evidence of their efficacy when administered in an infusion made with 30 grains (Gr. 2) of the leaves in half a pint of water, strained and sweetened, and taken twice or thrice daily. A similar method is reported to be successful in *articular rheumatism* (Pouget and Peyraud, *Amer. Jour. of Med. Sci.*, April, 1853, p. 492). According to Pliny, serpents will avoid even the shadow of the ash, and he affirms as of his own knowledge that if a snake is enclosed in a circle of ash-leaves in the centre of which are burning coals, it will plunge into the fire rather than touch the leaves. A similar fact or superstition exists in regard to the white ash (*F. americana*). On the land where it grows no rattlesnake will be found, "and it is the practice of hunters and others having occasion to traverse the woods in the summer months to stuff their boots or shoes with white-ash leaves as a preventive of the bite of the rattlesnake." We have several times known this precaution to be taken with full faith in its efficacy. A vinous preparation of the white ash is alleged to be useful in *dysmenorrhœa* and associated uterine disorders.

FUCUS VESICULOSUS.—BLADDER-WRACK.

Quereus marina.—Sea-wrack, Kelp-ware, Blachtang, Out-weed, E.; *Fucus* (*Varech*) *vésiculeux*, Fr.; *Blasentang*, *Seetang*, *Meereiche*, G.

Fucus vesiculosus, Linné. Bentley and Trimen, *Med. Plants*, 304.

Nat. Ord.—Algæ, Fucoidææ.

Description.—It grows on rocky shores of the North Atlantic and of the North Pacific Ocean, attains a length of 2 to 4 feet (0.6–1.2 M.), and has a flat branching thallus $\frac{1}{2}$ to 1 inch (12–25 Mm.) wide, with the margin entire and a distinct midrib through its entire length. The air-vesicles are usually in pairs, separated by the midrib, spherical or oblong in shape, and occasionally attaining the size of a hazel-nut. The fructification is found at the end of the branches, forming more or less elongated receptacles, with many globular conceptacles containing the numerous minute oblong antheridia and few larger globose sporangia. In the fresh state bladder-wrack is of a brownish-green color, which becomes nearly black on drying. It has the peculiar odor of sea-weeds and a mucilaginous and saline taste.

Allied Species.—*Fucus nodosus*, Linné (*Fucodium nodosum*, Agardh), is 4 to 6 feet (1.2–1.8 M.) long, and has a narrower frond or thallus without midrib, and with single vesicles, which are ovate or oblong, and usually large.

Fucus serratus, Linné, has a veined and serrate frond without vesicles.

Fucus siliculosus, Linné, s. *Cystoseira* (*Halidrys*, *Lynghye*) *siliquosa*, Agardh. The frond is very narrow, 2 to 4 feet (0.6–1.2 M.) long, with short branches, articulated vesicles of a pod-like appearance, and lanceolate flattened tubercular fructification.

Fucus natans, Linné, s. *Sargassum bacciferum*, Agardh, is the *Gulf-weed* of the Atlantic Ocean, and is often found in immense masses floating in the sea. The frond is terete, and has linear and serrate branches and globular aculeate and stipitate vesicles of the size of a pea.

Constituents.—These plants are very similar in composition. They contain mucilage, marmite, odorous oil, a bitter principle, and between 14 and 20 per cent. of ash, calculated for the dried plant. Gödeschen, James, and others found the mineral constituents of the bladder-wrack, as collected from different places, to vary to the same extent. Marchand (1865) obtained from the ash of the bladder-wrack 0.719 per cent. of iodine and 0.603 of bromine, and from *F. serratus* 0.834 iodine and 1.007 bromine. Frisby (1880) obtained from anhydrous bladder-wrack .72 per cent. iodine, .84 bromine, and .47 chlorine; the ash amounted to 15.9 per cent.

Medical Action and Uses.—The medicinal virtues of *F. vesiculosus* depend apparently upon the iodine and bromine which it contains in common with the allied species of sea-weed. It has been applied externally, bruised, to enlarged *scrofulous* glands, and internally it was at one time recommended as a means of lessening *obesity*. It was administered chiefly in a decoction made with from 2 to 4 drachms (Gm. 8–16) of the plant in a pint of water, and was alleged not to occasion atrophy of the mammæ or testes, while it reduced the fat in a notable degree. For this purpose it had a brief vogue, but is now almost forgotten.

FUMARIA.—FUMITORY.

Fumeterre, Fr.; *Erdrrauch*, *Feldraute*, G.

Fumaria officinalis, Linné.

Nat. Ord.—Fumariaceæ.

Description.—Fumitory is a low annual about 12 inches (30 Cm.) high, and is common in the fields throughout Europe and more or less naturalized in most civilized countries. The entire plant is of a glaucous gray-green color; the stem is angular and much branched; the leaves are alternate, finely-dissected, compound, with spatulate or obovate-oblong rather acute lobes; the flowers are in terminal and axillary racemes, and have short, acute, and sharply-toothed sepals, and a pale-red and crimson or purplish corolla, which is one-spurred at the base. The fresh plant has a somewhat heavy odor and a saline, bitter, and rather acrid taste.

Constituents.—Winckler (1831) isolated *fumaric acid*, $C_4H_4O_4$, which had been obtained by Lassaigne (1819) from malic acid, $C_4H_6O_5$; the latter, heated to $150^\circ C.$ ($302^\circ F.$), is almost completely resolved into fumaric acid and water. Fumaric acid crystallizes in colorless prisms, volatilizes partly unaltered above $200^\circ C.$ ($392^\circ F.$), and when heated with hydriodic acid or under the influence of nascent hydrogen is converted into succinic acid. Peschier discovered the alkaloid *fumarine*. Pommier (1853) obtained it by exhausting the fresh herb with water acidulated with acetic acid and precipitating with ammonia. It is white, crystalline, bitter, not freely soluble in water, but soluble in alcohol. The analysis of Merck proved the presence of the usual constituents of herbs.

Medical Action and Uses.—This is one of many medicines reputed to be purifiers of the blood. Its bitter taste and its slightly laxative and diuretic qualities suggest its analogies with dandelion. Its reputation also is partly of the same kind as a remedy for *dyspeptic* derangements attributed to torpor of the liver, but generally due to constipation. But its greatest credit has been acquired in the treatment of diseases of the *skin* depending on scrofulous and other diathetic disorders. For *crusta lactea* a decoction of the plant in milk has been used topically. The expressed juice of the fresh plant is its most efficient preparation. A decoction or infusion may be made with an ounce of the herb to a pint of water (Gm. 32 to Gm. 500).

FIG 128.

Fucus vesiculosus, Linné: fructing branch, natural size.

FUNGUS CHIRURGORUM, *P. G.*—SURGEON'S AGARIC.

Agaricus (s. *Boletus*) *chirurgorum*, s. *igniarius*.—Spunk, Touchwood, E.; *Agaric de chêne*, *Bolet amadouvier*, *Amadou non-salpêtré*, Fr.; *Wundschwamm*, *Feuerschwamm*, *Zunder*, G.

Polyporus (*Boletus*, *Linné*) *fomentarius*, *Fries*.

Nat. Ord.—Fungi, Polyporei.

Origin.—This fungus grows on beech and oak trees in Southern and Middle Europe; it is sessile, obliquely triangular, and hoof-shaped, 4 to 12 inches (10 to 30 Cm.) broad, at the base 2 to 4 inches (5–10 Cm.) thick, brown-gray or whitish externally and yellowish-brown internally; the hymenium on the lower side is in the form of small tubular pores. This and the hard rind are removed and the fungus is cut into thin slices, which are soaked in water, boiled in weak lye, washed, and beaten with mallets until soft. It is then ready for surgical purposes. For use as tinder it is soaked in a saturated solution of nitrate of potassium before it is dried.

Description.—Surgeon's agaric is in thin, flat pieces, tasteless, inodorous or of a faint odor, of a cinnamon-brown color, glossy, very soft and velvety. Under the microscope it is seen to consist of interlaced filiform cells. It readily absorbs twice its weight of water, and when this is expressed and evaporated only a minute residue should be left.

POLYPORUS (*BOLETUS*, *Linné*) *IGNIARIUS* and *MARGINATUS*, *Fries*, yield a similar but harder product; the former grows on willows and other trees, and is internally rust-brown or dark cinnamon-brown, and very hard; the latter is found on oak and beech trees, and is internally yellowish, and not spongy.

Surgical Action and Uses.—On account of its combined lightness, elasticity, toughness, and porosity this substance has long been used to arrest *hemorrhage* from slight wounds, and especially from leech-bites. It should be secured in its place by a bandage or other pressure. When prepared with nitrate or with chlorate of potassium it may be formed into cylinders and used as a *moxa*. Its physical qualities give it a superiority over all other substances to be insinuated between the ulcerated skin and an *ingrown toe-nail*. The success of this treatment depends upon preventing any movement of the parts by means of a narrow strip of adhesive plaster wound around the toe.

FUNGUS MUSCARIUS.—FLY AGARIC.

Fly fungus, E.; *Agaric mouche*, *Fausse orange*, Fr.; *Fliegenschwamm*, G.

Amanita muscaria, *Persoon*, s. *Agaricus muscarius*, *Linné*.

Nat. Ord.—Fungi, Agaricini.

Origin.—This European fungus grows in autumn, chiefly under pine trees; allied poisonous species are met with in most countries. Some species of the same genus are edible.

Description.—The stalk is tuberous at the base, 3 to 6 inches (7 to 15 Cm.) high, and about $\frac{1}{2}$ inch (18 Mm.) thick, white. The cap (pileus) is 4 to 6 inches (10–15 Cm.) broad, at first globular, afterward flattish or convex, scarlet or orange-red, more or less covered with white warts, internally yellowish, and on the under side with white lamellate gills (hymenium). It has a disagreeable odor and a burning, acrid taste. Infused with milk, it is used for poisoning flies; hence the name.

Constituents.—The poisonous principle, according to Apoiger (1851), is a crystallizable acid soluble in ether and precipitated by acetate of lead. Letciller (1866) called it *amanitin*, which is a brown, amorphous, tasteless glucoside, insoluble in ether and not precipitated by lead salts or gallic acid. Schoonbrodt (1864) isolated a white crystalline powder, *agaricin*, by exhausting the alcoholic extract with 50 per cent. alcohol, evaporating and crystallizing from a mixture of alcohol and ether; it is insoluble in ether and sparingly soluble in water, and has at first an insipid, afterward sweet, bitter, and acrid taste. Sicard and Schoras (1865) announced that various toadstools contain a poisonous volatile alkaloid; the volatile alkaloid obtained by Apoiger had a very disagreeable odor, but was not poisonous. Schmiedeberg and Koppe (1869) separated a poisonous alkaloid, *muscarine*, $C_5H_{15}NO_3$, which is colorless, inodorous, crystalline, very deliquescent, insoluble in ether, and sparingly soluble in chloroform; it is a strong base, and yields deliquescent salts, which are precipitated by mercuric chloride, auric chloride, and potassium-mercuric iodide. It is accompanied by *choline*, $C_5H_{15}NO_2$, which was isolated by Harnack

(1876) as *amanitine*, and was afterward found by him identical with the choline of hog-bile.

Physiological Action.—*On Animals:* After subcutaneous injection of muscarine in a frog the heart loses by degrees its muscular force, and at last stands still in diastole. Although it cannot be stimulated, mechanically, to contract, its power may be restored by atropine, daturine, digitaline, duboisine, puturia, and pilocarpine. If the animal be already under the influence of atropine, muscarine will not produce its characteristic effects. In cats it causes increased salivary secretion, vomiting, diarrhœa, staggering gait, and the other symptoms mentioned below. In mammals generally large doses increase the frequency of the heart's pulsations while limiting their power, so that the organ grows more and more dilated and the blood-pressure declines. At the same time, as might be anticipated, the blood accumulates in the lungs and venous system, causing more or less cyanosis, with symptoms of asphyxia. Small doses, on the other hand, quicken without embarrassing respiration. In the latter cases the temperature is somewhat raised; in the former it is lowered. One of the most constant effects is salivation, which is proportioned to the dose administered; there may also be vomiting, with tardy diarrhœa, frequent defecation, and increased secretion of urine. The peristaltic action of the bowels is sometimes so vigorous as to be visible through the skin. The pupil is generally contracted.

On Man: In large doses it occasions violent and fatal symptoms. A case is on record in which several soldiers who had eaten of this fungus presented the following phenomena: anxiety, burning thirst, oppressed breathing, severe colic, a small and irregular pulse, lachrymation, cold sweats, sunken features, dimness of vision, contracted pupils, with a cyanotic hue of the nose, lips, hands, and feet; general twitching of the muscles, tetanoid or epileptoid spasms, distension of the abdomen, fetid evacuations from the bowels, delirium, and great anguish until death. Husemann relates that in 1859 five officers died from poisoning by this fungus, and states that the fatal termination may take place in from 5 to 12 hours, or not for 2 or 3 days (*Handbuch d. Toxicologie* (1862), p. 389). It is employed by many Siberian tribes to produce excitement and inebriation, and it imparts to the urine an intoxicating quality which continues for a considerable time after taking it. "A man, for example, may have intoxicated himself to-day by eating some of the fungus; by the next morning he will have slept himself sober, but by drinking a teacupful of his urine he will become as powerfully intoxicated as on the preceding day" (Pereira).

The toxic effects of *Fungus muscarius* resemble those of alcohol in some respects and of belladonna in others. Murrell quotes the following illustration (*Practitioner*, xxv. 89): "The natural inclinations of the individual become stimulated. The dancer executes a *pas d'extravagance*, the musician indulges in a song, the chatterer divulges all his secrets, the orator delivers himself of a philippic, and the mimic indulges in caricature. Erroneous impressions of size and distance are common occurrences: a straw lying in the road becomes a formidable object, to overcome which a leap is taken sufficient to clear a barrel of ale." It is stated by Cosserrat "that a young woman who had eaten some of these fungi ran about the house in her night-gown, beating her head against the wall and screaming like one possessed." Some American species seem to occasion analogous effects, for a person poisoned by one of them is said to have been affected "with wild apprehensive delirium" (Evans, *Phila. Med. Times*, xiii. 327).

A very interesting case of poisoning by this fungus which occurred at Calcutta is related by Dr. Chevers. An accomplished gentleman, of temperate habits, having partaken of some mushrooms at breakfast, went to court, and was surprised to find that he could not control his actions; every thing and person appeared to him ludicrous; he laughed immoderately in open court, and ridiculed in an absurd way his superior officer. After some hours he recovered, but was naturally alarmed at his attack, of which he did not suspect the cause. His physician, to console him, promised to return to luncheon, at which, among other dishes, were stewed mushrooms. Of these he ate, and before the meal was finished he became very much excited; every person appeared ridiculous; the most ordinary remark seemed full of fun and wit, and his laughter was immoderate. Every object appeared to him perfectly beautiful. These exaggerated sensations continued for some hours, and were put an end to by the administration of ipecacuanha, which caused him to disgorge a considerable quantity of the fungi still undigested. No after ill effects were experienced. It will be observed that in this narrative there is absolutely nothing to suggest or to be explained by the results of the physiological experiments above described. But in the fatal cases above referred to the cyanotic phenomena corresponded to the effects produced in animals by lethal doses of muscarine.

The hypodermic injection of one-third of a grain of Merck's muscarine occasioned

contraction of the pupil, profuse perspiration, free salivation, and running at the eyes and nose, and sometimes it purged and excited nausea and vomiting and a desire to pass urine. A like administration of one-thirteenth of a grain of pure muscarine produced these symptoms, with a sense of weight in, and determination of blood to, the head, flushed face, and giddiness. It is remarked as curious that while muscarine given internally contracts the pupil, its topical administration dilates it—in this respect resembling gelseminum (Murrell); and, as still more curious, and, indeed, as important in its bearing upon the relation of physiological results to therapeutics, “that pilocarpine, a sweater and salivator, which slows and weakens or arrests the frog’s heart, should antagonize muscarine, which is also a sweater and a salivator and stops the heart.”

Medical Uses.—At one time this fungus had a doubtful reputation for the cure of *epilepsy*. It was also used externally in the treatment of chronic *eruptions* and *ulcers* on the skin. Its most important use is to combat profuse *sweating*, for which purpose the related white agaric has long been employed, as is elsewhere stated. Dr. Murrell successfully used *Agaricus muscarius* in the treatment of twenty-six cases of the night-sweating of phthisis. He found that 5 minims of the 1 per cent. solution of the extract was the smallest dose on which reliance could be placed. It was given three times a day, or at intervals of about an hour before bed-time. It does not begin to act on the first night, but on each successive night becomes more efficient, and it stops the sweating without producing any abnormal dryness of the skin. Even in the dose of 15 minims it produced no bad effects. But care should be taken to test the activity of the preparation used by its power of arresting the action of the frog’s heart (*loc. sup. cit.*).

GALANGA.—GALANGAL.

Rhizoma (Radix) galangæ, P. G.; *Radix galangæ minoris*.—*Galanga*, Fr.; *Galgant*, G.

The rhizome of *Alpinia officinarum*, Hance. Bentley and Trimen, *Med. Plants*, 271.

Nat. Ord.—Zingiberaceæ.

Origin.—The galangal-plant resembles a flag, and has stems about 4 feet (1.2 M.) high, and white flowers, veined with red, in terminal racemes. It is indigenous to the island of Hainan in the south of China, and probably also to the adjacent mainland.

Description.—The rhizome appears in commerce in sections about 2 inches (5 Cm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–18 Mm.) in diameter, frequently with one or two short branches. It

FIG. 130.

FIG. 129.

Galanga.

Galanga: transverse section, magnified 3 diam.

has externally a rust-brown color, and is longitudinally striate and transversely marked with the short remnants of the leaf-sheaths. It is rather tough, breaks with a somewhat fibrous fracture, is internally pale grayish-brown, and on transverse section shows the nucleus-sheath as a dark-colored circular line, enclosing a central portion of about the same width as the cortical layer; the tissue contains scattered oil-cells and wood-bundles, the latter being more numerous in the central portion. Galangal has an agreeable aromatic odor, which becomes more prominent on bruising the rhizome, and a pungent taste somewhat resembling that of ginger.

Constituents.—Galangal contains about $\frac{1}{2}$ per cent. of a pale-yellow or brownish-yellow volatile oil which is lighter than water, and, according to Vogel (1844), has the composition $C_{10}H_{18}O$. The water distilled from galangal contains ammonium carbonate (Vogel). The pungent taste of the rhizome, according to Bucholz, is due to a soft resin which has not been further examined. Brandes (1839) obtained by means of ether a brown oleoresin containing crystals of *kæmpferid*, which, when pure, are yellowish, pearly, tasteless, and inodorous, and are colored by sulphuric acid first yellow, afterward dark-green. Mucilage, starch, fat, and extractive matter are likewise present.

Allied Drug.—*ALPINIA GALANGA*, Willdenow, of Java, yields the *greater galangal*, *Radix galangæ majoris*, which is rarely seen in our commerce. It resembles the preceding, but is

longer and thicker, externally brown-red, internally grayish or buff-colored, and has a weaker odor and taste.

Medical Action and Uses.—Galangal is an aromatic, and therefore a local and general stimulant, resembling ginger in its qualities and effects. It was formerly held in high repute as a stomachic for promoting *digestion* and relieving *flatulence*. It was employed to correct nausea and prevent *vomiting* due to indigestible food, and also when they occurred in febrile diseases of a typhoid type. Its somewhat acrid taste renders it unsuitable for administration in powder, which may, however, be prescribed in the *dose* of 20 or 30 grains (Gm. 1.30–2.00). It may be given in an infusion made with an ounce (Gm. 32) of the bruised root to a pint of water. A tincture is also employed in the *dose* of a fluidrachm (Gm. 4).

GALBANUM, U. S., Br., P. G.—GALBANUM.

Gummi-resina galbanum.—Galbanum, F.; Mutterharz, Galban, G.

The gum-resin obtained from *Ferula galbaniflua*, Boissier et Buhse, and probably from other allied plants. Bentley and Trimen, *Med. Plants*, 128.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—This plant is indigenous to Northern Persia. The stem is about 5 feet (1.5 M.) high; the radical leaves are large, triangular, decompound-pinnate, and pinnatifid, with the ultimate sections linear and obtuse; the stem-leaves are small; the fruit is somewhat winged near the face of the mericarps; the ribs are prominent and slender, and the oil-tubes solitary in each groove and absent in the commissure, or often there are two narrow ones. The plant, with the one noticed below, was originally (1844) described by Boissier under the name of *Fer. erubescens*, subsequently (1856) as *F. gummosa*.

Fer. rubricaulis, Boissier, grows in Southern (and probably also in Northern) Persia, and has the leaves with wider segments and the oil-tubes narrower and more numerous than the preceding. *Fer. Schair*, Borszezon, a native of the Kirghee country, yields also a gum-resin similar to galbanum, which, however, does not appear to be collected. The gum-resin exudes spontaneously, and, as far as known, no incisions are made to promote the exudation. It enters commerce chiefly through Russia and from the Levant.

Description.—The best quality of galbanum is met with in tears varying in size from a pin's head to a pea and larger; sometimes it is soft and semifluid. The tears adhere to one another, forming a more or less compact mass; they are of a reddish-, brownish-, or greenish-yellow color externally, internally whitish or yellowish, with a waxy gloss, and are somewhat translucent. It has a peculiar, unpleasant balsamic odor and a disagreeable, bitter, and acrid taste. Moistened with alcohol, a fine purple color will be produced on the addition of a little strong hydrochloric or nitric acid. Hydrochloric acid remaining in contact with galbanum for about an hour acquires a red color, and on the gradual addition of alcohol and warming the mixture to 60° C. (140° F.) becomes transiently dark violet-colored (difference from ammoniac, which is not colored). Water in contact with galbanum shows a blue fluorescence on the addition of a minute quantity of ammonia-water.

Lump galbanum consists sometimes of soft or harder masses, in which some tears are distinctly observed; sometimes a mass is offered which from its odor and behavior seems to be of a different origin.

For medicinal use galbanum should be exposed to a low temperature until brittle, then powdered, and by sifting freed from the impurities.—P. G.

Constituents.—According to the older analyses by Neumann, Pelletier, and others, galbanum contains 6 to 8.5 per cent. of volatile oil, 15 to 20 per cent. of gummy matter, and 60 to 66 per cent. of resin, besides 7 to 14 per cent. of impurities. Volatile fatty acids were found by Moessmer (1861) in the emulsion remaining after distilling off the volatile oil. The *volatile oil* is colorless, turns yellowish and thick on exposure, varies in specific gravity between .88 and .92, has the boiling-point 160° to 165° C. (320° to 329° F.), is dextrogyre, and consists of several hydrocarbons of the composition $C_{10}H_{16}$. The resin is yellowish-brown, soluble in ether, alcohol, carbon disulphide, and alkalies. On being heated it yields a beautiful indigo-blue volatile oil which, according to Kachler (1871), consists of a colorless oil, $C_{10}H_{16}$, boiling at 240° C. (364° F.), and of a deep-blue oil, $C_{30}H_{48}O_3$, which boils at 281° C. (538° F.), appears to be identical with the blue portion of the oil of German chamomile, and yields with potassium a hydrocarbon, $C_{30}H_{48}$, the solution of which in much aqueous ether gives with an ethereal solution of bromine an azure-blue color, changing to green and brown. Galbanum resin, treated with fusing

potassa, yields several volatile fatty acids and *resorcin*, the solution of which is colored dark-purple by ferric chloride (Hlasiwetz and Barth, 1864).

An aqueous infusion of galbanum on the addition of ammonia assumes a blue fluorescence, which disappears again on the addition of an acid. This reaction is due to *umbelliferon*, $C_8H_6O_3$, which may be obtained in colorless needles by heating galbanum with hydrochloric acid to $100^{\circ} C.$ ($212^{\circ} F.$), agitating the liquid with ether or chloroform, and evaporating the latter solution. It was first obtained by C. Sommer (1859) from sunbul-root, and has since been procured from various umbelliferous resins and from mezerion. It crystallizes from hot water in colorless rhombic prisms which melt at $240^{\circ} C.$ ($464^{\circ} F.$) and sublime without decomposition. It is easily soluble in ether and alcohol, but dissolves sparingly in cold water, the latter solution showing a blue color in reflected light; when fused with potassa it yields resorcin.

Off. Prep.—Emplastrum asafetidæ, *U. S.*; Empl. galbani, *U. S., Br.*; Pilula assafetidæ comp., *Br.*; Pil. galbani comp., *U. S.*

Medical Action and Uses.—Galbanum is generally described as partaking of the virtues both of asafetida and ammoniac, affecting the nervous system like the former, and acting as a local irritant like the latter. Applied to the skin, it occasions a papular eruption, and, if the true skin is exposed, causes it to ulcerate. Upon the system generally it probably acts as a stimulant, for in large doses it is said to cause fulness of the head and tension of the pulse. Moreover, its therapeutical virtues are observed only in cases that call for stimulation; these are such as the resins and gum-resins are applicable to, and especially *chronic bronchitis, chronic intestinal, uterine, and vaginal catarrh, amenorrhæa*, etc. In most of these cases its effect is to lessen excessive mucous secretion. It is seldom given alone, and hence virtues are apt to be attributed to it that belong to its associated medicines. In the compound galbanum pill it is united with asafetida and myrrh. Even for external use it is associated with other irritants. The *dose* of galbanum is from 5 to 20 grains (Gm. 0.30–1.30). It is best administered in emulsion.

GALEGA.—GOAT'S RUE.

Herba rutæ caprarix.—*Galega, Rue de chèvre, Fr.; Geisraute, G.*

Galega officinalis, Linné.

Nat. Ord.—Leguminosæ, Papilionacæ.

Description.—Goat's rue is found in the countries bordering on the Mediterranean and northward to Central Europe. It has a perennial several-headed root and an erect stem about 3 feet (90 Cm.) high; the smooth, oddly-pinnate leaves are furnished with six or eight pairs of lanceolate or ovate-lanceolate, obtuse, and finely mucronate leaflets $\frac{3}{4}$ to 2 inches (2–5 Cm.) long, and with lanceolate stipules, which are sagittate on one side. The purplish or whitish flowers are in axillary racemes, and produce narrow almost cylindrical legumes. The herb is inodorous and has a mucilaginous and somewhat bitter and astringent taste. Its constituents have not been investigated.

Medical Action and Uses.—*Galega* was at one time held to be diaphoretic, diuretic, and anthelmintic, and was used as a stimulant in nervous affections of an *hysterical* or *spasmodic* nature, in low *fevers*, and especially in the *plague*. It is said, also, to favor the *mammary secretion*. In Europe *galega* is no longer used, except in domestic medicine.

GALIMUM.—CLEAVERS.

Bedstraw, E.; Caille-lait, Gallait, Fr.; Labkraut, G.

Nat. Ord.—Rubiaceæ, Stellatæ.

Description.—The following species have been used:

GALIMUM APARINE, Linné.—Cleavers, *E.*; Grateron, Rièble, *Fr.*; Klebkraut, *G.*—It grows in thickets in North America, Europe, and Northern Asia, has a weak, retrorsely prickly, quadrangular stem 3 or 4 feet (0.9–1.2 M.) long; linear-lanceolate and mucronate leaves in whorls of six or eight, which are prickly, roughened on the midrib and margin; small whitish flowers, and fruits composed of two united one-seeded carpels, which are armed with hooked prickles.

G. TRIFLORUM, Michx.—Sweet-scented bedstraw, *E.*—It is indigenous to North America, resembles the preceding, but has elliptic-lanceolate slightly rough leaves in whorls of six, three-flowered peduncles, and acquires an agreeable odor on drying.

G. MOLLUGO, Linné.—Whiptongue, *E.*; Caille-lait blanc, *Fr.*; Waldstroh, *G.*—This

plant is indigenous to Europe, somewhat naturalized in the United States, has a smooth stem, oblanceolate or oblong-linear, somewhat rough and mucronate leaves in whorls of eight, and long panicles of whitish flowers yielding smooth fruits.

G. vertum, *Linné*.—Yellow bedstraw, *E.*; Caille-lait jaune, *Fr.*; Megerkraut, Liebfrauenstroh, *G.*—This perennial herb has a light-reddish root, whorls of eight linear rough leaves, compact panicles of yellow flowers, and smooth fruits; it is a European plant sparingly naturalized in the United States.

Constituents.—The plants contain either *galitanic* or *aspartic acid*, both producing green precipitates with iron salts. They likewise contain *citric*, *oxalic*, and *rubichloric acids*, a bitter principle, and the common principles of herbs (*R. Schwarz*; *Vielguth*). *Von Cotzhausen* (1876) determined the odorous principle of *Galium triflorum* to be *coumarin*, to which is also due the agreeable odor of the nearly-allied *Asperula odorata*, *Linné*, known in France as *aspérule odorante* and in Germany as *Waldmeister*. The roots of several species, like *Galium tinctorium*, *Linné*, contain red coloring matter resembling that of the allied *Rubia tinctorum*, *Linné*, and are popularly known as *wild madder*. The leaves of others, like *Galium circæzans*, *Michaux*, and *G. lanceolatum*, *Torrey*, have a sweet liquorice-like taste, and the plants are sometimes called *wild liquorice*.

Medical Action and Uses.—*Galium verum* has been used in Europe chiefly as a diuretic in *dropsy* and *jaundice*, and for *scaly skin diseases*, especially of a *scrofulous* nature. It has been alleged to cure *epilepsy* and *cancer* of the tongue. The fresh plant, reduced to a paste in a mortar, is used in Great Britain as a poultice for chronic *ulcers* (*Edinb. Med. Jour.*, xxix. 173). Notwithstanding the virtues attributed to it at various times, it does not seem to have established its claims to confidence. A decoction of *galium* is prepared with half an ounce of the plant to a pint of water (Gm. 16 to Gm. 500) and given in wine-glassful doses.

GALLA, U. S., Br.—NUTGALL.

Gallæ, *P. G.*; *Galla halepense*, *G. turcica*, *G. levantica*, *G. tinctoria*, *G. quercina*.—*Galls*, *E.*; *Noix de galle*, *Galle de chêne*, *Fr.*; *Galltöpfel*, *Gallen*, *G.*

Exerescences on *Quercus lusitanica*, *Webb*, var. *infectoria*, *De Candolle* (*Q. infectoria*, *Olivier*), caused by the punctures and deposited ova of *Cynips* (*Diplolepis*, *Latreille*) *Gallæ tinctoriæ*, *Olivier* (Class Insecta, Order Hymenoptera). *Steph.* and *Church*, *Med. Bot.*, plate 152; *Bentley* and *Trimen*, *Med. Plants*, 249.

Nat. Ord.—Cupuliferæ.

Origin.—*Quercus lusitanica* is a polymorphous species indigenous to the basin of the Mediterranean, the leaves varying between ovate and obovate, mostly rounded at base and acute at apex, variously and either obtusely or acutely toothed or lobed. The dyer's oak is a small tree, or oftener a shrub, 4 to 6 feet (1.2–1.8 M.) high, and is found in the eastern section of the Mediterranean basin from Greece to Persia. The tender bark of the young branches is punctured by the female of the hymenopterous insect named above, and one or more eggs are deposited in the wound. The irritation produced by this operation causes the formation of an excrescence enclosing the larva, which undergoes therein its transformations. The term *gall* is generally used to designate such excrescences formed upon any part of a plant in consequence of the puncture of an insect.

Description.—Nutgalls are nearly globular, about an inch (25 Mm.) or less in diameter, with a short stipe and a nearly smooth surface, or, more frequently, more or less tuberculated in the upper portion. They are dense, and in color externally of a deep blackish olive-green or blackish-gray; if the gall remains upon the branch, it gradually becomes lighter, and finally of a pale yellowish-brown tint, the texture becoming spongy and the weight decreasing at the same time. Galls are hard, but are readily broken with a hammer, exhibiting a more or less close granular fracture, which has sometimes a waxy lustre. Internally, they are yellowish- or pale brownish-gray, with a central nucleus or cavity containing either the more or less fully developed insect or pulverulent fragments of the cellular tissue. In the latter case the insect has usually escaped through a cylindrical canal which it has bored from the

FIG. 131.

FIG. 132.

Entire.

Nutgall.

Section.

cavity to the surface, the outer aperture being just below the middle and having a diameter of $\frac{1}{12}$ to $\frac{1}{8}$ inch (2-3 Mm.). The cellular tissue of the nucleus, if still present, is mostly filled with small starch-granules and surrounded by a layer of thick-walled cells forming a shell, on the outside of which is the cellular tissue containing the tannin. This tissue has often a radiated appearance near the shell, and contains toward the surface small scattered bundles of vascular tissue. Nutgalls are nearly inodorous and have a very astringent taste. Light, spongy, and whitish-colored nutgalls should be rejected.

FIG. 133.

Chinese Nutgalls.

galls which are produced upon the European oaks by different species of *Cynips* are of a lighter color and more spongy texture, but have an astringent taste and contain tannin.

Constituents.—The principal constituent of nutgalls is *tannin* or *gallotannic acid*, of which they contain about 60 per cent. Bowman (1869) assayed selected galls, finding 80 per cent., and in white galls only 30.7 per cent. 2 or 3 per cent. of gallic acid is likewise found, together with some sugar, resinous and albuminous matter, and, as stated before, starch in the nucleus.

Pharmaceutical Uses.—In the preparation of tannic and gallic acids, and for Tinct. gallæ, Unguent. gallæ, *U. S.*, *Br.*, and Unguent. gallæ cum opio. *Br.*

Allied Drugs.—CHINESE AND JAPANESE GALLS, although known from a much earlier period, were not a regular article of commerce until Pereira (1844) directed attention to them again.

FIG. 134.

Japanese Nutgalls.

and protuberances; their origin has been referred to *Rhus japonica*, *Siebold*. C. Hartwich (1881) found also their pubescence quite dense and light-brown, and the tissue to contain unaltered starch-granules; while Chinese galls have the pubescence less dense and greenish-brown, and the starch is pasty.

VALLONEA.—Valonia, Acorn-cups, *El.*: Valloné, Vêlanède, Gallon, *Fr.*: Knopperrn, Walonen, *G.*—Several varieties are occasionally met with. *Hungaria valonia* are the cups of *Quercus Robur*, *Linne*, rendered irregular in shape and more or less winged by the excrescences produced from the sting of *Cynips Quercus calycis*. *Oriental valonia* consist of the unaltered fruit-cups of *Quercus Vallonea*, *Kotschy*, and of several allied species or varieties of *Qu. Egilops*, *Linne*, indigenous to South-eastern Europe and the Levant; they are about an inch (25 Mm.) or more in diameter, have thick spreading or recurved scales, possess a strongly astringent taste, and are largely employed for tanning. The cups of our indigenous species are likewise astringent.

AMERICAN NUTGALLS, as obtained from *Quercus alba*, *Linne*, and other species, are light and spongy, and generally not very rich in tannin. The galls from *Quercus virens*, *Aiton*, produced in Texas, are more analogous to Aleppo galls, but not tuberculate; they contain about 40 per cent. of tannin. The so-called *California oak-galls*, recently introduced, are derived from *Quercus lobata*, *Engelmann*, are about 2 inches (5 Cm.) in diameter, orange-brown and somewhat glossy externally, soft and spongy within, and appear to contain much tannin.

TAMARISK GALLS are collected from *Tamarix orientalis*, Forskal, which grows in Southern and South-western Asia. They are $\frac{1}{4}$ to $\frac{1}{2}$ inch (3-12 Mm.) thick, subglobular, knotty, and are said to contain from 40 to 50 per cent. of tannin. Similar galls are obtained in Algeria and Morocco from *Tam. africana*, Poiret. The brown-red, fibrous, bitter, and astringent bark of *Tam. gallica*, Linné, and the leaves of the same plant, are used in Southern Europe.

Medical Action and Uses.—From the most ancient times nutgall has been used in medicine for its astringency. This property is due to gallotannic acid, but a bitter extractive ascribed to nutgall gives it a tonic action. These qualities account for its efficacy in the treatment of chronic *diarrhœa*. It has been used as an *antidote* to tartar emetic and poisonous vegetable alkaloids; and whatever degree of efficacy it then exerts is probably due to its constringing the stomach and delaying the absorption of its contents. An infusion made with from half an ounce to an ounce (Gm. 16-32) of coarsely-powdered nutgall in a pint (Gm. 500) of boiling water, may be given in the dose of a wine-glassful three or four times a day, for the purposes referred to; and it may be locally applied to the *relaxed mucous membrane* of the mouth, throat, vagina, and rectum.

GARCINIA.—MANGOSTEEN.

Mangostane, Fr., G.

Several species of *Garcinia*.

Nat. Ord.—Guttiferae (Clusiaceae).

Origin.—The trees belonging to the genus *Garcinia* inhabit tropical countries, and are chiefly found in India and the East Indian islands. They have unisexual or subdioecious flowers with four sepals, four petals, and numerous stamens, which in the pistillate flowers are often reduced to staminodes; the ovary is four- to ten-celled, each cell containing one seed; the fruit is a fleshy berry.

Description.—*GARCINIA MANGOSTANA*, Linné, is a large tree with a bitter and very astringent bark, and glossy elliptic-oblong or oblong-lanceolate leaves. The fruit is of the size of an ordinary orange, of a brown or brown-gray color, mottled with yellow and crowned by the sessile four-lobed stigma. The pericarp is bitterish and astringent, somewhat spongy, and encloses six or eight seeds, which are covered with a white juicy pulp of a delicious odor and taste. W. Schmid (1855) isolated from the pericarp, besides tannin, golden-yellow *mangostin*, $C_{20}H_{22}O_5$, which crystallizes in scales, is fusible, soluble in alcohol and ether, and colored yellowish-brown by alkalies and green-black by ferric salts.

The fruit of *Garcinia Kydia*, Roxburgh, which is dark-yellow and of the size of a small orange, and of *Garc. pedunculata*, Roxburgh, which is much larger and of a yellow color, contain an acidulous pulp which is very inferior to that of the first species.

GARCINIA INDICA, Choisy, s. G. *purpurea*, Roxburgh, s. *Brindonia indica*, Du Petit-Thouars (Bentley and Trimen, *Med. Plants*, 32), is a medium-sized tree, with oblong-lanceolate or oblong-oval, glabrous leaves, and with a dull-red or purplish fruit of the size of a small orange and containing from five to eight seeds imbedded in an acid purple pulp, which is used in India in curries and in the dried state. The seeds are about $\frac{1}{2}$ inch (12 Mm.) long, oblong-reniform, somewhat compressed and wrinkled, and contain an oily embryo. After bruising the seeds and boiling them with water an oil collects on the surface, which is moulded by hand into egg-shaped balls, and is known as *kokum-butter* or *concrete oil of mangosteen* (Beurre de Kokum, Suif de Goa, Fr.; Kokum-butter, G.). This oil is in various-shaped cakes, has a whitish or yellowish color, and is firm, friable, and crystalline. J. Bouis and D'Oliveira Pimentel (1857) obtained from the seeds by ether 30 per cent. of oil, melting near 40° C. (104° F.), and containing about 50 per cent. of tristearin. Flückiger found after saponification also myristic and oleic acid. After filtration, whereby brown tannic matters are removed, the oil begins to melt at 42.5° C., fuses entirely at 45° C., and concretes again at 27.5° C. (*Pharmacographia*).

Allied Fruits.—*MAMMEA AMERICANA*, Linné, a guttiferous tree of the West Indies, has a brown-yellow, subglobular fruit about 5 inches (12 Cm.) in diameter and containing three or four ovate-oblong rough seeds. The fruit, which is known as *mammee-apple*, has a leathery bitter rind and contains a yellow aromatic pulp of a very agreeable taste. The fruit of *LUCEMA* (*ACHRAS*, Linné) *MAMMOSA*, Jussieu, *Nat. Ord.* Sapotaceae, is likewise known in the West Indies as *mammee*; it is an ovoid-oblong, rust-brown, and rough berry about 6 inches (15 Cm.) long, having a yellow or reddish sweet, mucilaginous pulp, and containing usually one large yellowish-brown polished seed.

GARCINIA KOLA, Heckel, is the *male kola* or *kola bitter* of Western Africa. The somewhat

triangular seeds contain a yellowish-white embryo, which consists of a large radicle, and has a bitter, astringent, and somewhat coffee-like taste.

Medical Action and Uses.—The bark, the wood, and also the rind of the fruit of *G. mangostana* are very astringent, and have been employed in the treatment of *diarrhœa*, *dysentery*, *leucorrhœa*, and *gonorrhœa*, as a gargle in *tonsillitis*, in decoction as a lotion for foul ulcers and *prolapsus* of the *rectum* and *vagina*, etc. The concrete oil of *G. indica* has been chiefly used in some pharmaceutical preparations.

GAULTHERIA, U. S.—GAULTHERIA.

Folia gaultheria.—Wintergreen, Teaberry, Partridgeberry, Boxberry, Checkerberry, E.; *Feuilles de gaulthérie* (*de palommier*), *Thé du Canada*, *Thé de Terre-neuve*, Fr.; *Canadischer Thee*, *Bergthee*, G.

The leaves of *Gaultheria procumbens*, Linné (s. *G. humilis*, Salisbury; *Gaultiera repens*, Rafinesque). Bigelow, *Med. Bot.*, t. 22; Bentley and Trimen, *Med. Plants*, 164. *Nat. Ord.*—Ericaceæ, Ericineæ.

Origin.—Teaberry is found in cool damp woods, usually in the shade of evergreens, in Canada and the United States. The plant is a small shrub with a slender creeping stem and ascending branches, about 5 inches (12 Cm.) high, bearing the alternate evergreen leaves near the summit, axillary, nodding, whitish flowers, and five-celled berry-like pods, which are enclosed in the bright-red fleshy calyx. The leaves are collected late in summer or in autumn.

FIG. 135.

Leaf of *Gaultheria procumbens*, natural size.

Description.—The leaves are short-petiolate, about 1½ inches (4 Cm.) long and ¾ to 1 inch (18–25 Mm.) wide, obovate or roundish-oval in shape, with a wedge-shaped base, coriaceous in texture, mucronate and slightly toothed, the teeth having the elongated points appressed to the thickish margin; they are smooth, of a glossy-green color above, and paler beneath. The odor is agreeably aromatic, taste astringent and aromatic.

Constituents.—We are not acquainted with a complete analysis of the leaves. They contain a volatile oil (see *OLEUM GAULTHERIÆ*) and tannin. Jefferson Oxley (1872) found, besides grape-sugar, gum, coloring matter, and a principle analogous to gallic acid, *arbutin*, *urson*, and *ericolin*—principles which are likewise present in the leaves of *chimaphila* and in *uva ursi*.

Medical Action and Uses.—*Gaultheria* is stimulant and somewhat astringent. It has sometimes been employed as a substitute for Chinese tea in country places, where it is also popularly used as an *emmenagogue* and *galactagogue* and in chronic *bowel complaints*. In the former cases a hot infusion of the leaves is best; in the latter a cold infusion, made with about an ounce of the leaves to a pint of water (Gm. 32 to Gm. 500) may be taken freely. The action and most important uses of *gaultheria* are described in connection with its oil.

GELATINA.—GELATIN.

Gelatine, Fr.; *Gelatin*, G.

Origin and Preparation.—When bone-cartilage, animal skin, tendons, and ligaments are boiled for a long time with water, they become soluble therein, and on cooling the solution forms a jelly. During the boiling the animal tissues are placed upon a sieve or perforated diaphragm which is inserted above the bottom of the boiler. When sufficiently saturated the solution is drawn off and allowed to cool, the jelly being then cut into thin cakes, and these are placed upon nettings to dry. When made from carefully-selected material (fresh bones) it constitutes the *gelatin* of commerce, known also as *artificial isinglass*. The offal of slaughter-houses and of tanneries yields an impurer gelatin, known as *colla*, s. *colla animalis*, s. *glutinum*—glue, E.; colle, colle forte, Fr.; Leim, G. The importation into the United States of gelatin has increased from 139,000 pounds in 1876 to 476,000 pounds in 1882.

Properties.—Gelatin is met with in commerce in very thin, rectangular, transparent pieces bearing the impressions of the netting upon which it has been dried, or in smooth sheets which are either thin and transparent, or thicker, more or less porous, and opaque. It is not unfrequently cut into shreds, and the transparent kind is often variously colored.

Glue is in similar pieces, but usually thicker, and varies in color between pale-yellowish and dark-brown, or nearly black in the commonest varieties, and has an offensive animal odor, which is more apparent after it has been dissolved in hot water. To be adapted for dietetic or pharmaceutical purposes gelatin should not alter in color after being digested in hot water, and the solution should be free from smell.

It is to a small extent soluble in cold glycerin, dissolves freely in hot water, forming on cooling a tremulous transparent jelly, and is insoluble in alcohol and ether. Its solution in water is not precipitated by dilute solutions of alum, ferric chloride, or subacetate of lead (distinction from *chondrin*), but yields precipitates with tannin, chlorine-water, corrosive sublimate, and platinic chloride. The tissues yielding gelatin likewise unite with tannin, forming leather. Gelatin dissolves in acetic and in dilute mineral acids, the solutions being known as *liquid glue*. When its solution in water is boiled for a long time it loses the property of gelatinizing on cooling. By dry distillation gelatin yields carbonate of ammonium and a number of volatile bases, which are contained in *Dippel's animal oil*. Boiled with solution of potassa or with sulphuric acid, ammonia, *glycocoll*, $C_4H_9NO_2$, and *leucin*, $C_6H_{13}NO_2$, are obtained among other products.

Composition.—Gelatin, also called *glutin*, consists of about 50 per cent. of carbon, 18 of nitrogen, 6.5 of hydrogen, 25 of oxygen, and 0.5 of sulphur.

Chondrin, which is obtained from the permanent cartilages by boiling with water, has a similar composition, but contains less nitrogen and more oxygen. In addition to the differences pointed out above, it is distinguished from gelatin by being precipitated by acetic and the mineral acids.

Pharmaceutical Uses.—Gelatin is employed as a reagent for *estimating tannin*, a convenient solution for the purpose being made by dissolving about 50 Gm. of it, together with 8 or 10 Gm. of alum, in a liter of distilled water; before use the strength of the solution must be determined with a fresh solution of pure tannin (see p. 104). It should, however, be remembered that the different tannins require for complete precipitation different amounts of gelatin, so that the results obtained are not absolutely correct. The pectic acid of oak-bark, according to P. Büchner (1867), is likewise precipitated by a solution containing both gelatin and alum.

Gelatin is used for preparing the ordinary *court plaster* (see p. 569) and for the coating of pills. (See *PILULÆ*.) Dried in very thin layers, it has been recommended, under the name of *devorative* or *folding capsules*, for the administration of powders, the thin sheets being used in precisely the same manner as paper, except that after the introduction of the powder they are permanently closed by moistening the edges, and are swallowed, together with the powder, after having been softened by being dipped in water. *Medicated gelatin* is prepared by pouring a concentrated solution of gelatin, in which the medicinal substance has been dissolved, upon a polished and perfectly level surface; the sheet thus obtained is then divided into squares or disks in such a manner that each represents a definite weight of the medicine. *Gelatin capsules* are made by dipping oblong moulds of the desired size and shape into a gelatin solution; after the surface has been sufficiently coated, the capsule, while still pliant, is removed, filled with the powder or liquid, and the orifice closed by a drop of solidifying gelatin; or for extemporaneous use an empty capsule is slipped over the open end of another containing the medicine.

Within a few years so-called *medicinal pearls*, containing ether or other liquid, have been introduced. Hager recommends them to be made of gelatin, gum-arabic, sugar, and honey rolled out into sheets, one of which, while still rather soft, is placed upon an iron plate containing suitable cavities, into which the mass sinks; the liquid is then introduced, the orifices are closed by another sheet of the gelatin compound, the whole covered by a second iron plate having depressions exactly corresponding to those of the first, and after screwing the plates together their position is reversed. The pearls are finally separated by subjecting the entire arrangement to powerful pressure.

Gelatin has also been used as a base for the preparation of *medicated suppositories*, vaginal as well as rectal, and for *bougies*. The material consists of about 3 parts of gelatin, which, after having been soaked in water, is dissolved in 7 parts of glycerin. The medicating substance should be soluble in the vehicle. Substances containing tannin are evidently not adapted for this mode of medication.

Liquid glue may be made in various ways, either by dissolving glue in acetic acid or by adding to a strong aqueous solution of glue, nitric acid, equal to one-sixth or one-seventh of the weight of the glue. A solution of glue in spirit of nitrous ether is stated to be very serviceable, particularly if a little caoutchouc has been added to it. A solution of phosphoric acid in water, nearly neutralized by ammonium carbonate, has likewise been

recommended for preparing liquid glue. The glue becomes water-proof by the addition of about 2 per cent. of potassium bichromate immediately preceding the application of its solution, and afterward exposing to the sunlight.

Gelatin also forms the chief constituent of the mass of which *hæctographs* are made: 40 parts of gelatin or light-colored glue, after having been softened by water, are dissolved with the aid of heat in 100 parts of glycerin, to which 10 parts of simple syrup and 5 parts of mucilage of gum-arabic have been added; the scum is removed and the mass poured out. Finely-powdered whiting or terra-alba is sometimes added to the mass. *Hæctograph inks* are made by dissolving 1 part of aniline violet or other similar compound in 10 parts each of acetic acid and water. After copying, the ink which is still adhering to the mass is removed with a sponge moistened with diluted vinegar.

Medical Action and Uses.—Physiological experiments prove that gelatin alone cannot support animal life, but that it may become nutritious when combined with other substances, as in soup prepared from meat. In the form of calves'-feet jelly it is employed during convalescence from acute disease, but its utility probably depends in great part upon the sugar, wine, and spices that season it. Solutions of gelatin are sometimes used to allay the irritation of the mouth, stomach, etc. produced by *corrosive poisons*. It has been given by enema as a lenitive in *ulceration of the rectum*, and a coating of it has been applied to *cutaneous eruptions* to protect them from the air. It is also dissolved in baths for chronic diseases of the skin, to remove the crusts or epidermic scales or simply to render the skin soft and pliable. For this purpose about a pound (Gm. 500) of gelatin dissolved by boiling in water is added to the bath when it is taken. Gelatin has also been used in the same manner as starch to prepare an immovable apparatus for *fractures*, etc. Catti has proposed the introduction of gelatinous cylinders or pencils charged with astringent or disinfecting agents into the nostrils in the treatment of chronic *coryza*, *ozæna*, etc.; and Pick strongly advocates the use of medicated gelatin, instead of ointments, in the treatment of *diseases of the skin*, and especially of *eczema* (*Centraltb. f. Ther.*, i. 147).

GELSEMIUM, U. S.—GELSEMIUM.

Radix gelsemii.—Yellow jessamine or jasmine, E.; *Racine de gelsemium*, *Jasmin sauvage*, Fr.; *Gelsemienwurzel*, *Giftjasmin*, G.

The rhizome and roots of *Gelsemium* (*Bignonia*, *Linneé*; *Lisianthus*, *Miller*; *Anonymos*, *Walter*) *sempervirens*, *Aiton*, s. *Gels. nitidum*, *Michaux*, s. *G. lucidum*, *Poirét*. Bentley and Trimen, *Med. Plants*, 181; Meehan, *Native Flowers*, i. 9.

Nat. Ord.—Loganiaceæ, Gelsemieæ.

Origin.—The yellow jessamine is indigenous to the Southern United States, growing in moist woods from Virginia to Florida and Alabama, and flowering early in spring, beginning to bloom in Florida in January, and farther north in March or April. It has a high climbing stem with opposite, ovate-lanceolate, entire, smooth, and coriaceous leaves, and solitary or axillary clusters of very fragrant flowers, which have a bright-yellow, funnel-form, five-lobed corolla 1 to 1½ inches (25–38 Mm.) long, and produce a flattened two-celled fruit containing four to six winged seeds in each cell. The root and the subterraneous stem are the parts used in medicine.

Description.—The rhizome is about an inch (25 Mm.) or more in diameter, is

FIG. 136.

Gelsemium sempervirens, *Aiton*: transverse section of root.

externally brown-yellow with purplish-brown longitudinal lines, and breaks with a tough splintery fracture, showing silky bast-fibres in the inner closely-adhering bark, a porous yellowish wood which is traversed by whitish medullary rays, and a darker-colored central pith. The roots are thinner, similar in color externally, beset with numerous thin fibres, and marked by irregular longitudinal wrinkles and small scars. A transverse section shows a thin yellowish-brown bark covering a hard, pale-yellowish medullum without a central pith, but radially striate by numerous whitish medullary rays. Fragments of the thin purplish over-ground stem are occasionally present in the commercial article. The drug has a peculiar heavy aromatic odor, which is more marked when a larger quantity is examined. The taste of the bark is not unpleasantly bitter; that of the wood is but slight.

Constituents.—An analysis made by M. H. Kollock (1855) proved the existence of an alkaloid, *gelsemine*, besides volatile oil, starch, and gummy pectinaceous and resin-

ous principles. The existence of the alkaloid was corroborated by C. L. Eberle (1868) and Prof. Wormley (1870); the latter obtained it (1877) by acidulating a concentrated tincture with acetic acid, precipitating the resin by water, concentrating the aqueous filtrate, removing from the solution *gelsemic* or *gelseminic acid* by ether, liberating the alkaloid by carbonate of sodium, and extracting it by ether or chloroform. Dragendorff (1878) recommended a similar process, removing gelsemic acid from the acid liquid by chloroform, and, after rendering the liquid alkaline, extracting the alkaloid with benzine and chloroform. It is amorphous, white, intensely bitter, strongly alkaline, and slightly soluble in cold water, in which its salts dissolve quite readily. Sulphuric acid produces a red color, changing to purple when heated, nitric acid a greenish, and hydrochloric acid a yellowish, color. C. A. Robbins (1876) obtained for it the empirical formula $C_{11}H_{19}NO_2$, and observed that cerous-ceric oxide imparts to the sulphuric acid solution a rose-cherry-red color. E. Schwarz (1882) has studied its reactions, and considers the most characteristic one to be with sulphuric trihydrate in excess, followed by potassium chromate (or in place thereof manganese dioxide, ceric oxide, or lead dioxide), when a cherry-red color is produced, changing to dingy gray-brown, and finally to green. Fröhde's reagent colors rose-brown or red-brown, finally yellowish-green. *Brouardet-Boutmy's reagent* (potassium ferricyanide, followed by weak solution of ferric chloride; this produces Prussian blue with most of the *ptomaines* or cadaver alkaloids) gives an intense green color; *Schneider's reagent* (sugar and strong sulphuric acid) colors cherry-red; and *Selmi's reagent* (iodic acid suspended in sulphuric acid), rose-red.

Robbins regarded the *gelsemic acid* to be identical with *æsculin*, $C_{15}H_{16}O_9$, a principle present in the bark of the horse-chestnut (*Æsculus hippocastanum*, *Linne*), in quassia, red saunders, etc. It crystallizes in colorless prisms, is soluble in 400 parts of cold water, and nearly insoluble in chloroform and ether, possesses a bitterish taste, and yields with alkalis in extremely dilute solutions a characteristic fluorescence, being yellow in transmitted and blue in reflected light, and destroyed by acids. *Æsculin* is a glucoside, being split by dilute acids into glucose and *æsculetin*, $C_9H_6O_4$, which is colored yellow by alkalis and dark-green by ferric chloride. Dragendorff and Schwarz noticed the strong fluorescence of gelsemic acid, but did not examine into its alleged identity with *æsculin*. But Prof. Wormley (1882) has shown the former to be quite distinct; it crystallizes very readily, dissolves in 2912 parts of water, in 330 parts of ether, and, with a yellowish color, in cold or warm sulphuric acid, and is insoluble in hydrochloric acid; its solution is precipitated by silver nitrate, brownish-yellow, darkening to blue-black; by corrosive sublimate, yellowish, crystallizing in needles; by bromine, green, turning bluish and brownish; by copper sulphate, dirty brown, turning dull red and crystallizing; and by lead acetate, yellow, crystallizing. Wormley obtained on an average 0.2 per cent. of the alkaloid and 0.4 per cent. of the acid. The ash of air-dry root amounts to 4 per cent. (Kollock).

Off. Prep.—Extractum gelsemii fluidum, Tinctura gelsemii, *U. S.*

Physiological Action.—*On Animals:* Gelsemine induces paralysis both of sensation and motion, sometimes of the one first, and sometimes of the other, lowers the force and rate of the pulse and respiration, reduces the temperature, dilates the pupils, projects the eyeballs, and does not suspend the heart's action until after respiration has ceased. Death is apt to be preceded by intermittent tetanoid convulsions, which cannot be immediately reproduced like those excited by strychnine. Dr. Wormley found that $\frac{1}{8}$ grain given subcutaneously to a strong cat caused death in $1\frac{1}{2}$ hours, with symptoms of great debility; that $\frac{1}{6}$ grain given to a frog caused prostration, followed by tetanic convulsions and death in 4 hours; and when $\frac{1}{2}$ grain was injected into the peritoneum of a frog the animal opened its mouth convulsively, the jaws fell at intervals, and there was great muscular prostration. In 20 minutes the body was completely relaxed, and reflex irritability of the muscles was abolished, including that of the heart, which was arrested in diastole (*Am. Jour. of Phar.*, July, 1882, p. 343). According to Dr. C. G. Davis, the alkaloid hastens and intensifies the tetanizing action of strychnine (*Jour. Amer. Med. Assoc.*, ii. 128), doubtless by lowering the tone of the nervous system, just as it causes tetany when given alone. The results of Moritz's experiments may be summarized thus: Gelsemine produces in warm-blooded animals excitation, followed by depression, and even paralysis of the brain and spinal marrow. It first quickens, and afterward slows, the respiration and renders it shallower. On the heart it acts only through the respiration. Applied to one eye, it dilates the pupil and disturbs visual accommodation. The peculiar tremor caused by it in cold-blooded animals is of spinal origin, as are also its influence on the mode of respiration, as just described, and the slowing of the heart in the last stage of

the lethal action of the poison (*Archiv f. Pathol. u. Physiol.*, xi. 299; compare Rouch, *Bull. de thérap.*, civ. 527).

On Man: Applied topically to the eye, gelsemine dilates the pupil. A physician subject to supraorbital neuralgia found that the tincture, gradually increased in dose, produced in him a very agreeable sense of languor and tranquillity; then slight dizziness, impairment of vision, and drooping of the eyelids, a feeling of numbness, beginning in the scalp and gradually extending to the upper and then to the lower extremities, followed by impaired motility, embarrassment of the respiration, and feebleness of the heart's action. A still larger dose aggravated all these effects, and produced marked vertigo, almost total blindness, and decided ptosis (Williams). The characteristic symptoms of excessive and poisonous doses of gelsemium are these: Great prostration and muscular relaxation and incoördination, affecting the entire system, and conspicuously paralysis of the upper eyelids and of the lower jaw (after recovery muscular debility continues for several days); the tongue is also affected; in more than one case there were signs of spasm of the pharynx and larynx, causing extreme distress and suggesting the phenomena of hydrophobia; paralysis of the voluntary muscles is usual; the pupils are dilated; vision is double or greatly impaired; the face is congested; the mind is usually clear, but in some fatal cases coma or unconsciousness exists; the skin is warm and dry until the approach of death, when it grows cool and moist; the general sensibility is blunted, according to some observers; the respiration is slow, irregular, shallow, and gasping, and the pulse is generally stated to be low, small, feeble, irregular, and intermittent, but other observers declare that it is little or not at all affected, or that it, as well as the respiration, is more frequent than natural. Death takes place through the gradual arrest of the respiration, and usually without convulsions. Dr. Wormley collected twenty-five cases of gelsemium-poisoning, of which thirteen proved fatal. In five fatal cases occurring in adults and collected by ourselves the doses of the fluid extract were respectively, f3j, f3ss, f5ij, f5ij, and f5ij; in four similar cases observed in children the fatal doses were respectively f5ij, f5j, f5j, and 21 drops. In two more recent cases a child of three years was killed by about 12 minims of the fluid extract, and an adult man who took four doses of 15 minims each of the fluid extract, repeated at short intervals, died in less than 4 hours after the last dose was taken (Wormley). After death the heart is distended with liquid and dark-colored blood, the stomach is congested, and the brain rather pale. Very small doses of this drug may cause alarming symptoms. A lady suffering from trifacial neuralgia was prescribed a dose of 3 drops of fluid extract of gelsemium three times a day. From the first each dose caused paralysis of the bladder with incontinence of urine, lasting for an hour or two. About the twelfth day she began to experience its sedative effects, and on the following morning she was unable to move; the pulse was small and feeble, the respiration sighing and jerky, the pupils dilated, and the eyes suffused. Muscular paresis was most marked upon the right side of the body. The patient recovered, but the neuralgia was in no way modified.

Medical Uses.—Gelsemium appears to be one of the too-numerous remedies which have been used in a great variety of sthenic febrile diseases upon no better ground than their power of lowering the pulse and depressing the nervous system. Incalculable mischief has been caused by them, and still more is likely to be occasioned by gelsemium in febrile affections. Some of those persons who have most loudly eulogized it as an anti-pyretic have been at great pains to explain, in opposition to the popular doctrine, that heat is death and cold is life; that we have only to reduce the fever temperature to the normal standard or below it to cure febrile disease; and that, therefore, gelsemium will cure fever. Unfortunately for this mode of medical reasoning, gelsemium does not reduce the temperature, except in so far as it threatens to destroy life through its poisonous operation. But such is probably not the reduction that its advocates had in view. Among a host of incongruous diseases which are said to have been "cured" by this agent, the one in regard to which very positive testimony exists is acute or rheumatic *neuralgia*, especially of the first and second branches of the fifth nerve. The most usual testimony is, that the medicine is nearly inoperative when the pain affects the third branch of the fifth pair or the intercostal nerves. Yet there are cases in which, when the trigeminus alone is involved, it relieves the inferior dental even more than the other branches. Undoubtedly, acute attacks produced by cold are more promptly cured than others, as, indeed, they are by all remedies that cure neuralgia at all. Dr. Bulkley recommends the tincture of gelsemium for the relief of *itching* in chronic eczema, giving it in 10-drop doses every half hour or hour until the pruritus is relieved (*New York Med. Jour.*, Jan. 1881). Dr. Edson claims that the following lotion is of great service in

poisoning by *Rhus radicans*: $\mathcal{R}$. Acid. carbolic. ʒss; Ext. gelsemii f3ij; Glycerinæ ʒss; Aquæ ad. ʒiv.—S. To be kept applied on cloths, while internally 2 minims of fluid extract of gelsemium are given every 3 hours (*Med. Record*, xxii. 121). From 3 to 10 minims (Gm. 0.20–60) of the fluid extract, or three times that quantity of the tincture, may be given every 2 hours. Like digitalis, aconite, veratrum, and antimony, it may, by reducing the pulse, prove useful in some attacks of *congestion of the brain, mania, and meningitis*. It has been claimed that gelsemium produces tolerance of quiniæ in certain cases intolerant of the anti-periodic alone; that it is efficient in convulsions produced by teething or by indigestion; that it exhibits peculiar virtues in rattlesnake-bites; that it expedites labor due to uterine rigidity, and relieves various forms of uterine congestion, etc. (Davis, *loc. cit.*). The evidence in favor of these claims does not appear to be sufficient. The proper *antidote* for poisoning by gelsemium is morphia hypodermically administered. General stimulation by mechanical means, rubefacients, and heat, and the administration of ammonia, coffee, and alcohol, the last hypodermically, should be employed, after the stomach has been evacuated by mustard and water, sulphate of zinc, tickling the fauces, etc.

GENISTA.—DYERS' BROOM.

Dyers' green-weed, Wood-waxen, E.; Genêt des teinturiers, Fr.; Fürberginster, G.

The young branches of *Genista tinctoria*, Linné.

Nat. Ord.—Leguminosæ, Papilionacæ.

Description.—Dyers' broom is a low shrub, 18 to 24 inches (45–60 Cm.) high, indigenous to Asia and Europe, and has been naturalized in the eastern part of the United States. The young erect branches are striately angled and have alternate sessile lanceolate entire bright-green leaves with a ciliate margin and 1 to 1½ inches (25–37 Mm.) in length. The bright-yellow flowers are in elongated racemes, and produce linear flat legumes, each containing from five to eight globular-obovate yellowish seeds. The recent plant, when bruised, has a rather refreshing odor and a mucilaginous afterward bitter and acrid taste.

Constituents.—Analyzed by Cadet de Gassicourt, the usual constituents of plants were found, but the principle giving the bitter and acrid taste was not isolated. The volatile oil is of a yellowish-green color, and the yellow coloring matter is stated to resemble that of the *weld* (*Reseda luteola*).

Medical Action and Uses.—The flowers and the seeds are both emeto-cathartic. In Russia dyers' broom was formerly vaunted as a remedy, or rather as a prophylactic, for *hydrophobia*. It is hardly necessary to add that the belief in it was groundless. Much better founded was its reputation in *dropsy*. In the early part of the present century the French government published a formula for the cure of dropsy, which consisted of the powdered seeds of this plant. It was given in the *dose* of a drachm in 6 ounces (Gm. 4 in Gm. 200) of white wine, followed in an hour by 2 ounces (Gm. 64) of olive oil to mitigate its operation. Its action and uses are very similar to those of scoparius.

GENTIANA, U. S.—GENTIAN.

Gentianæ radix, Br.; *Radix gentianæ*, P. G.; *Radix gentianæ rubræ (vel luteæ vel majoris)*.—*Gentian-root, E.; Racine de gentiane (de gentiane jaune), Fr.; Enzianwurzel, Bitterwurzel, Rother (Gelber) Enzian, G.*

The root of *Gentiana lutea*, Linné. Steph. and Church, *Med. Bot.*, plate 132; Bentley and Trimen, *Med. Plants*, 182.

Nat. Ord.—Gentianacæ.

Origin.—Gentian is indigenous to the mountainous regions of Southern and Central Europe as far north as Central Germany. It has a thick hollow stem 2 to 4 feet (0.6–1.2 M.) high, opposite, entire, five- to seven-nerved leaves, and axillary clusters of pedicellate flowers with a bright-yellow, five-lobed, spotted corolla, and producing a one-celled, ovate capsule containing numerous oval, compressed, and winged seeds.

Description.—The fleshy and branching one-headed to several-headed root attains a length of 2 to 3 feet (60–90 Cm.) and a diameter of about an inch (25 Mm.) or less, but appears in commerce always in shorter pieces, the thicker ones being longitudinally sliced before drying. Beneath the abrupt or concave somewhat conical heads they are closely annulated, the lower portion being deeply wrinkled longitudinally, with an overlapping bark in the longitudinally split pieces. The root is of a yellowish-brown color, the surface darker and grayish, the fracture short, of a slight waxy lustre, and with

numerous minute brown dots. The transverse section shows a faint radiating arrangement only near the dark cambium-line, and a fleshy medullium which is about six times thicker than the bark. Liber-fibres and wood-fibres are wanting, and are replaced by axially somewhat elongated parenchyma; the spiral and scalariform ducts are accompanied by sieve-tubes. The root is very hygroscopic, contains 14 to 18 per cent. of water, and is tough and flexible in moist weather. It has a faint but heavy characteristic odor, which is more prominent in a hot infusion; its taste is sweetish, then intensely bitter, but free from astringency or acidity. The importation of gentian into the United States during the seven years 1875-82 averaged 113,854 pounds annually.

FIG. 137.

*Gentiana lutea.*

The roots of other European species of *Gentiana* are occasionally collected with or in place of the one recognized by the Pharmacopœia; they closely resemble the latter, and have the same medicinal properties:

GENT. PURPUREA, *Linné*, with yellowish-purple flowers, is indigenous to the Pyrenees, Alps, Apennines, Norway, and Northern Asia, and has a many-headed (eight to ten) shorter and thinner root, which is darker brown internally. *G. PANNONICA*, *Scopoli*, with reddish- or blackish-purple flowers, indigenous to the mountains of Austria, has a scarcely-annulated, shorter, thinner, and darker root than the official. *G. PUNCTATA*, *Linné*, with straw-yellow, purplish punctate flowers, is found in the Alps and eastward to the Balkan Mountains; it is likewise many-headed and of a grayish yellow-brown color.

Constituents.—Kromayer (1862) was the first who isolated the pure bitter principle, which in many previous analyses had been obtained in an impure extract-like form. The crystalline *gentianin* of Henry and Caventou (1821) was in 1837 proven, by Trommsdorff and by Leconte, to be a yellow crystalline principle, subsequently named *gentisin*, *gentisic*, and *gentianic acid*, contaminated with some of the bitter matter. On washing the alcoholic extract of gentian with cold water to remove the bitter principle, afterward with some cold ether to remove fat, and crystallizing the residue from alcohol, *gentisic acid*, $C_{14}H_{10}O_5$, is obtained in bright-yellow, tasteless crystals requiring 5000 parts of water, 2000 parts of ether, and nearly 500 parts of cold alcohol for solution; it is soluble in alkalies and by ferric chloride colored brown (Leconte). Patch (1881) determined it to be soluble in 230 parts of cold and 120 parts of hot alcohol, and in 400 parts of ether, to become dark-green with nitric acid, and to dissolve unchanged in sulphuric acid; it melts above $100^{\circ} C.$, and on cooling congeals crystalline. Hlasiwetz and Habermann (1875) obtained from it, by fusion with caustic potassa, *phloroglucin*, *acetic* and *oxysalicylic (gentisinic) acid*, the latter being $C_7H_6O_4$ and isomeric with protocatechuic acid. The infusion of gentian yields with gelatin a slight precipitate, which, after having been washed with water, is not colored dark by ferric chloride. J. Ville (1877) regarded gentisin as a kind of tannin, and proposed to call it *gentio-tannic acid*. But after the separation of pectin compounds the infusion yields no precipitate with gelatin, and fresh hide fails to remove any principle reacting with ferric salts. Prof. Patch (1881), however, has shown that the resinous matter is associated with a principle giving some reactions of tannin—namely, a greenish-black color with ferric chloride, and precipitates with cinchonidine sulphate, tartar emetic, and gelatin, after, respectively, 2, 6, and 24 hours; this principle has not been isolated.

Gentiopierin, $C_{20}H_{30}O_{12}$, the bitter principle of gentian, is contained in the aqueous solution of the alcoholic extract, from which it is absorbed by animal charcoal; this is boiled with alcohol, the solution concentrated, treated with lead oxide to remove color, freed from lead by sulphuretted hydrogen, agitated with ether, and crystallized. It is very soluble in water and ordinary alcohol, insoluble in ether, dissolves with alteration in alkalies, and by dilute acids is split into glucose and *gentiogenin*, $C_{14}H_{16}O_5$, which is yellowish-brown, bitter, insoluble in water, and has the same composition as *physalin* (from *Physalis Alkekengi*). Kromayer states that crystallizable gentiopierin is obtainable only from fresh, not from dried, gentian-root.

Gentian contains no starch, but a considerable amount of pectin and 12 to 15 per cent. of an uncrystallizable sugar, to which the hygroscopic nature of the root is due. A. Meyer (1882) obtained a slightly-sweet, fermentable crystalline sugar, *gentianose*, $C_{16}H_{26}O_{31}$, which does not reduce Fehling's solution. By fermentation a potable spirit is obtained from it in Switzerland and Southern Germany. The air-dry root yields 8.28 per cent. of ash, consisting mainly of calcium carbonate (Flückiger).

Off. Prep.—Extractum gentianæ, *U. S. Br.*; Ext. gentianæ fluid., *U. S.*; Infusum gentianæ comp., *Mistura gentianæ, Br.*; Tinct. gentianæ comp., *U. S., Br.*

American Gentians.—Several of the blue-flowering gentians of North America are botanically very similar, and some confusion has existed concerning their identity, which is best shown by placing the species and their synonyms together, as at present recognized by Gray. We thus have—

(1) *G. puberula, Michx.*; *G. Saponaria*, var. *puberula* (Gray's *Man.*, edit. 1); *G. Catesbæi, Elliott*; and *G. Elliottii, Chapman*.

(2) *G. Saponaria, Linné*; *G. Catesbæi, Walter*.

(3) *G. Andrewsii, Grisebach*; *G. Saponaria, Frölich*; *G. fimbriata, Vahl*.

The first species is indigenous to the States south of North Carolina, and to most States from the Alleghanies to the Mississippi; the second is met with from the mountains of North Carolina to Southern Pennsylvania, and westward to Illinois; the third species is common in the Middle States and northward. We believe that the *blue gentian-root*, as found in commerce, is collected indiscriminately from the above three species. It is the *Gentiana Catesbæi, U. S. 1870*.

The subterranean part of these plants consists of an indistinctly annulated head about $\frac{1}{2}$ inch (13 Mm.) long and $\frac{1}{8}$ inch (3 Mm.) thick, which, at its base, is usually divided into a number of fleshy nearly simple rootlets about 3 inches (37 Mm.) or more in length. When dry they are of a pale-brownish color, with a distinct yellow or orange hue, and short, deep longitudinal wrinkles, devoid of fibres, quite brittle, and breaking with a short or somewhat spongy fracture, which is pale-yellow. The bark is thick and the ligneous cord quite thin. The odor and taste are gentian-like. We have found it occasionally mixed with a root of unknown origin of similar dimensions and appearance, but having a gray hue, a tough fibrous bark, and a sweetish scarcely bitter taste.

From experiments made with the root we conclude that its constituents are probably identical with those of *G. lutea*.

Medical Action and Uses.—Gentian is a pure and simple bitter. In moderate doses it excites the appetite and strengthens the digestion and does not constipate. If used too long or too freely, it is apt to occasion headache and a full pulse and to render the sweat and urine bitter. It is a valuable remedy for *atonic dyspepsia*, such as accompanies general debility from any cause or that which is apt to occur in persons of a gouty habit. It was formerly used in the cure of mild intermittent fevers. The nominal dose of gentian in powder is from 10 to 30 grains (Gm. 0.60–2.00), but it is always prescribed in the form of extract, fluid extract, or compound tincture, all of which are officinal.

American gentian is employed to some extent in popular practice in the southern portion of the United States for the same diseases and in the same manner as European gentian.

GERANIUM, *U. S.*—GERANIUM.

Cranesbill-root, E.; *Racine de geranium maculé, Bec-de-grue tacheté, Pied-de-corneille, Fr.*; *Fleckstorchschnabel-Wurzel, G.*

The rhizome of *Geranium maculatum, Linné*. Bigelow, *Med. Bot.*, i. t. 8; Bentley and Trimen, *Med. Plants*, 42.

Nat. Ord.—Geraniaceæ.

Origin.—This perennial herb is very common in rich woods in most parts of Canada and the United States, and it flowers from April to July. The stem is from 1 to 2 feet (30–60 Cm.) high; the hairy leaves, when old, become blotched with white, and are palmately five- or seven-lobed, with wedge-shaped divisions, which are coarsely toothed above; the light-purple flowers are in loose terminal umbels; the fruit is long-beaked, with five one-seeded carpels, which separate when ripe, curving upward together with the style, which separates from the beak. The horizontal rhizome should be collected late in summer or in autumn.

Geranium maculatum: rhizome and transverse section of rhizome and rootlets, natural size.

Description.—It is 2 to 3 inches (5–7 Cm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–12 Mm.) in diam-

eter when fresh, little branched, but tuberculated with the remnants of the stems, longitudinally wrinkled, with indistinct nodes, dark-brown externally, pale red-brown internally. It breaks with a nearly smooth fracture, showing a thin bark and the small, yellowish, broadly wedge-shaped wood-bundles arranged in a circle near the cambium, separated by broad medullary rays, and enclosing a large central pith. It has no odor; its taste is purely astringent. The rootlets are mostly on the lower side, and are much shrunk, fragile, and branched into hair-like fibres.

Constituents.—The analyses of Staples (1829) and Bigelow (1833) indicate, besides tannin, the presence of starch, pectin, sugar, mucilage, etc. Bowman (1869) found 13 to 17 per cent. of tannin, which has not been further investigated.

Off. Prep.—*Extractum geranii fluidum*, U. S.

Allied Plants.—*GERANIUM ROBERTIANUM*, *Linne*.—Herb Robert, *E.*; Herbe à Robert, *Fr.*; Ruprechtskraut, *G.*—It grows in shady thickets and woods in Europe, in the United States, and in Canada, has an erect branching stem, deeply three- or five-divided leaves, with the divisions twice pinnatifid and the lobes ovate and mucronately toothed, and rose- or purplish-colored flowers. It has a strong rather unpleasant odor and a bitterish, saline, and astringent taste. It contains tannin and a bitter principle.

ERODIUM (*GERANIUM*, *Linne*) *CICUTARIUM*, *L'Héritier*.—Storksbill—indigenous to the Levant and Southern Europe, is sparingly naturalized in the United States. It has a low spreading stem, pinnate leaves with the leaflets sessile and pinnatifid, and pale-reddish flowers. The odor of the bruised plant resembles that of carrot.

ERODIUM MOSCHATUM, *Aiton*, is found near the Mediterranean and in Southern Africa, and resembles the preceding, but has a rather strong musk-like odor.

Medical Action and Uses.—Geranium is a pure astringent, and may be profitably used in the treatment of subacute and chronic *diarrhœa*. A decoction of it in milk is employed in *cholera infantum*. A decoction, made with an ounce of the root in 1½ pints of water boiled to a pint, is sometimes used in *aphthæ* of the mouth and fauces, in relaxed conditions of the *throat*, *vagina*, and *rectum*, to restrain internal *hæmorrhages*, and to cure *leucorrhœa*, *gleet*, etc. The *dose* may be stated at from 20 to 40 grains (Gm. 1.30–2.60) of the powdered rhizome or from 1 to 2 fluidounces (Gm. 32–64) of the decoction.

Geranium Robertianum, like the official plant, has been much valued in Europe for its astringent and cleansing virtues, and employed in the treatment of *sore throat*, superficial inflammations and eruptions of the *skin*, in engorgement of *glands*, *ophthalmia*, etc. Internally, it was given as a diuretic for the relief of *gravel*, also for *hæmorrhages*, etc.

Erodium moschatum was used as a diaphoretic.

Erodium cicutarium attracted some attention in 1859 as a diuretic in *dropsy*, and in 1863 similar reports of its efficacy were published. A decoction was made with 2 ounces of the whole plant in 3 pints of water reduced to 2 pints, and it was prescribed in doses of 4 or 5 fluidounces three times a day.

GEUM.—WATER-AVENS.

Radix caryophyllatæ aquaticæ, *Radix benedictæ sylvestris*.—*Racine de bénoite aquatique* (*de bénoite des ruisseaux*), *Fr.*; *Sumpfnelkenwurzel*, *Wasser-Benedikten-Wurzel*, *G.*

The rhizome, with the rootlets, of *Geum rivale*, *Linne*.

Nat. Ord.—*Rosacæ*, *Dryadæ*.

Origin.—This perennial plant grows in wet meadows and moist woods in hilly localities of North America from Pennsylvania northward, and is likewise indigenous to Central and Northern Europe and Northern Asia. It has a stem 1 to 2 feet (30–60 Cm.) high, with lyrate or interruptedly pinnate root-leaves and trifoliate or three-lobed stem-leaves, the leaflets or lobes being obovate or cuneate-oblong; the bell-shaped calyx is purplish-brown; the five petals are clawed, purplish-yellow, and veined.

Description.—The rhizome is nearly horizontal, 2 to 3 inches (5–7 Cm.) long, about ¼ inch (6 Mm.) thick, somewhat branched, tuberculate above from the bases of the stems, and there densely beset with red-brown hairy leaf-sheaths. It is externally blackish-brown, breaks with a rather short and waxy fracture, and has a thin purplish-brown bark, brown-gray pith, and small distant light-colored wood-wedges. It has a very faint somewhat clove-like odor and a bitterish-astringent taste.

Water-avens has not been analyzed; its constituents are probably similar to those of the yellow-flowered *Geum urbanum*, *Linne*, or *avens*, which grows in Europe in woods and shady places, and has an oblique or perpendicular rhizome 1 or 2 inches (25–50 Mm.) in length, abrupt below or passing into the main or tap-root; it is hard, dark-brown, tuberculate, and beset with dark-brown membranous scales; the numerous thin fibres are pale-

brown and 3 to 4 inches (7-10 Cm.) long; the wood is in five or six broad and rounded wedges and encloses a large purplish pith. It has a distinct clove-like odor and a bitter astringent taste. It is known in Europe as *radix caryophyllata*. *Geum japonicum*, *Thunberg*, resembles it in appearance and properties, but has a brown horny centre.

Constituents.—Avens, according to Buchner (1844), contains a small quantity of a volatile oil possessing acid properties, about 3 per cent. of tannin, and a bitter principle which appears likewise to possess acid properties. The remaining constituents, sugar, fat, resin, etc., are not of medicinal importance.

Medical Action and Uses.—Water-avens is in its action very like avens, *G. urbanum*. Both are very astringent and more or less tonic. Like other agents with these qualities, it is apt to derange the digestion and cause vomiting if too freely given. It has been employed in all forms of disease of the mucous membranes depending upon relaxation and attended with excessive and altered secretions, including atonic *dyspepsia*, *diarrhœa*, *bronchorrhœa*, *leucorrhœa*, etc. It has also been used in chronic *rheumatism*, *scrofula*, slight *intermittent fever*, and in *menstrual derangements* depending on debility. The *dose* is represented by about 30 grains (Gm. 2) of the powdered root, but it is best administered in a decoction made by boiling an ounce (Gm. 32) of the root in a pint of water, which may be given in *doses* of 1 or 2 fluidounces.

GILLENIA.—GILLENIA.

Indian physic, *Indian hippo*, *American ipecac*, *Bowman's root*, E.; *Racine de gillénie*, Fr.; *Gillénienwurzel*, G.

The rhizome, with the rootlets, of *Gillenia* (*Spiræa*, *Linne*) *trifoliata*, *Moench*, and of *Gillenia stipulacea*, *Nuttall* (*Spir. stipulata*, *Willdenow*).

Nat. Ord.—Rosaceæ, Spirææ.

Origin.—Both species are perennial herbs indigenous to the United States, the first being found almost exclusively east of the Alleghanies from New York south to Georgia; the other is found from New York westward and southward to Alabama. The plants are 2 to 3 feet (60 to 90 Cm.) high, branched, with nearly sessile, trifoliate, doubly serrate, or incised leaves, and loose corymbs of pale rose-colored or white flowers, the calyx of which is tubular and constricted at the throat, the five unequal petals being long linear-lanceolate. The two plants are readily distinguished by their stipules, which in *G. trifoliata* are awl-shaped and entire, and in *G. stipulacea* are large, leaf-like, ovate, and incised. The rhizome and rootlets are employed.

Description.—The rhizome of *G. stipulacea*, which is usually found in commerce, is nearly horizontal, about 1 inch (25 Mm.) thick, very knotty from the numerous branches and remnants of stems. The larger rootlets are $\frac{3}{8}$ inch (9 Mm.) thick near the base, tortuous, irregularly branched; the smaller rootlets are undulated, and have a knotty or annulated appearance from the semicircular constrictions and the transverse fissures of the bark on one side and the depressions on the opposite side. The rhizome and rootlets of *G. trifoliata* are smaller and less knotty, the rootlets often smooth or indistinctly annulated, and with few or no transverse fissures. Both have a reddish- or grayish-brown color externally, and are hard and very woody, breaking with some difficulty except through the brittle bark. The bark of the rhizome is thin, the wood, about eight times thicker, of a whitish color, with several annual rings enclosing a thin pith and traversed by fine medullary rays. The bark of the root is of uneven thickness, in its outer layer brownish-red, the inner layer reddish-white, with numerous minute red resinous dots. The odor is very slight; the taste of the bark is bitter, not unpleasant, exciting the flow of saliva; the wood is tasteless.

Constituents.—The various analyses made of *Gillenia* have established the pres-

ence of starch, tannin, gum, albumen, fat, resin, etc. The bitter principle, *gillenin*, not quite pure yet, has been obtained by W. B. Stanhope (1856) in the form of a whitish powder having a slight odor and a very bitter taste, neutral to test-paper, soluble in water, alcohol, ether, and dilute acids, and colored blood-red by nitric acid. Its watery solution is stated to be precipitated by subacetate of lead, tartar emetic, and potassa, but not by tannin; $\frac{1}{2}$ grain caused much nausea. It was prepared by washing the alcoholic extract with water, treating the residue with very dilute sulphuric acid, adding magnesia, evaporating, and exhausting the dry mass with alcohol.

Medical Action and Uses.—The popular title of “American ipecacuanha” sufficiently indicates the prominent virtue of this medicine. It is a mild emetic. The *dose* is 20 to 30 grains (Gm. 1.30–2.00). The allied species, *G. stipulacea*, has identical qualities. Gillenin, when pure, will produce nausea and vomiting in *doses* of from $\frac{1}{2}$ to 1 grain (Gm. 0.03–0.06). Injected into the femoral vein of a dog, it excited vomiting.

GLECHOMA.—GROUND-IVY.

Herba hederæ terrestris.—*Lierre terrestre*, Fr.; *Gundermann*, *Gundelrebe*, G.

Glechoma hederacea, Linné, s. *Nepeta Glechoma*, Bentham.

Nat. Ord.—Labiatae, Nepeteae.

Description.—Ground-ivy is a creeping and trailing perennial which is common in Europe and naturalized in various parts of North America. The ascending branches are from 6 to 10 inches (15–25 Cm.) long, quadrangular, and have opposite petiolate leaves, which are 1 or $1\frac{1}{2}$ inches (25–38 Mm.) long, round-reniform, deeply crenate, green, and underneath often purplish. The blue or purplish flowers are in small axillary clusters, from two to five in number. The plant has a slight balsamic odor and a bitter somewhat acrid taste.

Constituents.—Like other plants of the same natural order, ground-ivy contains volatile oil, resin, fat, gum, sugar, and tannin; the bitter and acrid principle has not been investigated.

Medical Action and Uses.—Ground-ivy is said to act poisonously upon horses and sheep. It has been chiefly used in medicine in the treatment of *chronic bronchitis*, and its virtues in this affection are attested by medical evidence as well as by popular faith. It was at one time reputed to be a cure for consumption, by which was meant not the incurable disease which depends upon tuberculosis, but chronic bronchitis with mucopurulent sputa. It had also some reputation in catarrhal affections of the *urinary* organs and in atonic *dyspepsia*. Externally, the bruised herb has been applied in poultices or alone to indolent *ulcers*. An infusion may be made with an ounce (Gm. 32) of the herb to a pint of boiling water and given in wine-glassful doses.

GLYCERINUM, U. S., Br., P. G.—GLYCERIN.

Glycerina, U. S. 1870.—*Glycerine*, E.; *Glycérine*, Fr.; *Glycerin*, Oelsüss, G.

Formula $C_3H_5(HO)_3$. Molecular weight 92.

A liquid sweet principle obtained from fat and fixed oils, and containing not less than 95 per cent. of absolute glycerin.

Origin.—Glycerin, which is not found in the free state except in some rancid fats, exists in combination with the so-called fatty acids, forming compound ethers, which constitute most of the animal and vegetable solid and liquid fats. It is formed in small quantities during the fermentation of saccharine liquids. Scheele, who discovered it in 1779, called it *sweet principle of oils*. In the United States it was first manufactured in Philadelphia by Robert Shoemaker in 1846; at present it is extensively obtained by distillation in several cities, and in addition over 6,000,000 pounds are now annually imported, against about 2,000,000 pounds in 1878.

Preparation.—To obtain glycerin, fat must be decomposed into its proximate constituents, either by a caustic alkali, as in the manufacture of soap, or by oxide of lead, as in the preparation of lead plaster, or by the action of water at an elevated temperature under high pressure. The latter process, which was patented in 1854 by R. A. Tilghman, yields the acids of the fat and an aqueous solution of glycerin. Water which has been agitated with recently-prepared lead plaster is likewise such a solution, and the liquor from which soap has been separated contains glycerin, saline matters, and various organic impurities, which may be removed by treatment with the necessary precipitants and with charcoal, the solutions being finally evaporated and distilled with steam under

pressure. By fractional condensation most of the glycerin is obtained in a nearly anhydrous state.

In subjecting soap-liquors to dialysis the glycerin passes quite freely with the salts through parchment-paper, but not through "gutta-percha paper," which has been recently (1882) recommended for the purification of such impure glycerin. The purification of glycerin by distillation was patented by Wilson and Payne in 1854.

Properties.—Glycerin is a syrupy liquid having the specific gravity 1.28 at 15° C. (59° F.) (Pelouze); W. Lenz (1880), in determining the carbon in the various dilutions of glycerin, arrived at the following results:

100 per ct.,	1.2691 sp. gr.	75 per ct.,	1.2016 sp. gr.	50 per ct.,	1.1320 sp. gr.	25 per ct.,	1.0635 sp. gr.
95 "	1.2581 "	70 "	1.1889 "	45 "	1.1183 "	20 "	1.0498 "
90 "	1.2425 "	65 "	1.1733 "	40 "	1.1045 "	15 "	1.0374 "
85 "	1.2292 "	60 "	1.1582 "	35 "	1.0907 "	10 "	1.0245 "
80 "	1.2152 "	55 "	1.1455 "	30 "	1.0798 "	5 "	1.0123 "

The pharmacopœias require glycerin to have the density 1.250, *U. S.*, *Br.*, 1.225–1.235, *P. G.*, which, according to the above table, corresponds to 92½ and to 83½–87½ per cent. of absolute glycerin. It is transparent, colorless, inodorous, very sweet and somewhat warm to the taste, owing to its affinity for water, oily to the touch, without action upon litmus, and soluble in all proportions in water and alcohol; also in spirit of ether, but not in ether, chloroform, benzol, fixed oils, or volatile oils. Its great affinity for water has been long known; W. Willmott (1879) ascertained that this continues in a moist atmosphere until about twice its bulk of water has been absorbed. Heintz, Berthelot (1854), and others observed that at about 100° C. (212° F.) glycerin volatilizes in appreciable quantity, more readily, it seems, with the vapors of water; in a current of superheated steam it distils readily between 170° and 200° C. (338° and 392° F.). In contact with the air it distils only partially unchanged, the greater portion being destroyed, with the production of very acid *acrolein* among the empyreumatic liquids. Its boiling-point is 290° C. (554° F.). When anhydrous, it takes fire at 150° C. (302° F.) and burns quietly with a blue non-luminous flame, without giving off any disagreeable odor and without leaving any residue. It dissolves all deliquescent salts, is a solvent for many organic and inorganic compounds which are soluble in water or alcohol, and prevents the precipitation of some salts by alkalis and other reagents. By cooling glycerin to –40° C. (–40° F.) Berthelot could obtain it only as a nearly solid gummy mass. In 1867, Crookes saw it crystallized, after it had been exposed to cold weather while being transported, and Sarg obtained it in crystals by long-continued exposure to cold. The crystallization takes place slowly, but is greatly promoted even between 0° and 5° C. (32 and 41° F.) by the addition of a solid crystal to the cold glycerin. This behavior has been utilized for the purification of glycerin. The crystals are very deliquescent and melt at 22° C. (71.6° F.).

Chemically, glycerin is a triatomic alcohol; hence chemists often designate it *glycerol*, in analogy with other alcohols. It forms with acids three series of ethers, in which 1, 2, or 3 atoms of hydrogen are replaced by the corresponding number of univalent acidulous radicals. The so-called neutral fats are saturated ethers, like *tripalmitin*, $C_3H_5(C_{16}H_{31}O_2)_3$. A similar compound is *nitroglycerin* or *glonoin*, $C_3H_5(NO_2)_3O_3$, which is obtained on adding glycerin by drops to a mixture of concentrated nitric and sulphuric acids immersed in a freezing mixture, and afterward pouring into water. Nitroglycerin is a heavy colorless or yellowish oily liquid which is insoluble in water, readily soluble in alcohol and ether, very poisonous, and violently explosive. It forms the basis of *dynamite* and similar explosive mixtures.

When heated with an excess of phosphoric anhydride, $2H_2O$ are abstracted, and the glycerin is converted into *acrolein* or *allylaldehyd*, C_3H_4O , which is a light, very refractive, and volatile oily liquid, the vapors of which are extremely irritating to the eyes.

Glycerin dissolved in water and kept, with yeast, at a temperature of about 25° C. (77° F.), is converted into *propionic acid*, and with chalk and old cheese at 40° C. (104° F.) it yields *alcohol* and *butyric acid*. When slightly diluted with water and heated to just above 100° C. (212° F.) in the presence of oxalic acid, the latter will be decomposed into *carbonic* and *formic acids*. $C_3H_2O_4$ yields $CO_2 + CH_2O_2$; the formic acid may be afterward obtained by repeatedly diluting with water and distilling. Glycerin unites with the alkalis and alkaline earths to compounds soluble in water, the former also in alcohol; the latter are not precipitated by carbonic acid. It unites also with sulphuric and other acids. "If a fused bead of borax on a loop of platinum wire be moistened with

glycerin previously made slightly alkaline with diluted solution of soda, and after a few minutes held in a colorless flame, the latter is tinted deep-green."—*U. S.* This behavior was observed by Iles (1877), and recommended as a test for borates or for glycerin; but Klein (1878) showed that the reaction with borax takes place not only with glycerin, but with other polyhydric alcohols; and the conditions for these reactions have been elaborately investigated by Dunstan (1883), proving that sodium pyroborate is decomposed, with the formation of sodium metaborate and a boric ether, or, if water be present, free boric acid, the alcohol being regenerated.

Tests.—Glycerin is now rarely adulterated, but much being prepared for uses in the arts, where purity is not necessary, impure glycerin may at all times be met with in the market. Water, mucilage, dextrin, glucose, and perhaps cane-sugar syrup, would be used as adulterants. The first is detected by the specific gravity of the sample, the others by the brown color produced on mixing the sample with twice its bulk of concentrated sulphuric acid. Since cane-sugar syrup which has been exposed to the light for some time contains appreciable quantities of glucose, glycerin adulterated with either kind of sugar will become brown on being heated with solution of potassa or soda, and will yield a red precipitate when heated to boiling with a drop of solution of copper sulphate and an excess of potassa. The impurities may consist of saline matters should the glycerin have not been distilled, or of odorous compounds if insufficiently purified by distillation. The odor becomes apparent on warming the glycerin or rubbing it well upon the hand. Most of these compounds reduce nitrate of silver, and produce a more or less deep color when glycerin is diluted with a little distilled water and after the addition of a few drops of nitrate of silver heated to boiling. The same reagent will detect chlorides by the white precipitate produced. Diluted glycerin should not be colored or rendered turbid on being tested with sulphuretted hydrogen or sulphhydrate of ammonium (metallic salts), ammonium oxalate (calcium), or barium chloride (sulphuric or oxalic acid). The presence of butyric acid is readily determined by warming a mixture of glycerin with one-fourth its measure each of alcohol and sulphuric acid, when butyric ether, recognized by its odor of pineapple, will be given off. The most important tests for practical purposes are those with sulphuric acid and nitrate of silver. Goddefroy (1874) recommended the heating of glycerin in an open crucible to boiling, and then igniting it, when it should burn without diffusing the least smell or leaving the least residue. From these reactions the following tests have been formulated: "Glycerin should be neutral to litmus-paper. Upon warming a portion of 5 or 6 Gm. with half its weight of diluted sulphuric acid no butyric or other acidulous odor should be developed. A portion of 2 or 3 Gm., gently warmed with an equal volume of sulphuric acid in a test-tube, should not become dark colored (absence of cane-sugar). A portion of about 2 Gm., heated in a small open porcelain or platinum capsule upon a sand-bath until it boils, and then ignited, should burn and vaporize, so as to leave not more than a dark stain (absence of sugars and dextrin, which leave a porous coal). A portion heated to about 85° C. (185° F.) with test solution of potassio-cupric tartrate should not give a decided yellowish-brown precipitate, and the same result should be obtained if, before applying this test, another portion be boiled with a little diluted hydrochloric acid for half an hour (absence of sugars). After full combustion no residue should be left (metallic salts). Diluted with ten times its volume of distilled water, portions should give no precipitates or colors when treated with test solutions of nitrate of silver, chloride of barium, chloride of calcium, sulphide of ammonium, or oxalate of ammonium (acrylic, hydrochloric, sulphuric, or oxalic acids, iron, and calcium salts)."—*U. S.*

Pharmaceutical Uses.—Glycerin forms the base of the official *glycerita* (*glycerina*), and is a constituent of a number of official fluid extracts; also of *Linimentum potassii iodidi cum sapone*, *Br.*, and of *Mucilago tragacanthæ*, *U. S.* It is used for preserving pill-masses and certain extracts in a plastic condition, and for preventing fermentation and other changes in aqueous liquids containing organic matter in solution.

Medical Action and Uses.—The purest glycerin is irritating, on account of the avidity with which it abstracts moisture from the tissues, but commercial glycerin has sometimes a similar defect from containing nitric, sulphuric, or organic acids and other impurities. It is alleged that glycerin mixed with the food of animals tends to fatten them, while it diminishes the proportion of urea excreted. Catillon has shown that it sometimes augments and sometimes diminishes this excretion (*Bull. et Mém., etc.*, 1883, p. 133), but that, on the whole, the latter action prevails, and that during the use of the medicine the weight of the body increases. On the other hand, the careful experiments

of Munk led him to the conclusion that glycerin is not in the least degree nutritious (*Virchow's Archiv*, lxxvi. 119). If given in larger doses than can be digested, it may be detected in the urine, but it cannot be recognized in the feces or the sweat. In excessive doses (such as f3ss for every 2½ pounds of the animal's weight) its effects resemble those of alcoholic poisoning, including the gastric lesions found after death. Injected hypodermically, the same symptoms and lesions are produced. Similarly administered to frogs or injected into the veins of rabbits, it induces tetanic rigidity (*Archives of Medicine*, Oct. 1881).

Its richness in carbon suggested its use as a medicinal food, and especially as a substitute for cod-liver oil in *phthisis*, but, as in so many other instances, a little clinical experience showed the so-called scientific induction to be untrue. On theoretical grounds also it has been used in the treatment of *diabetes*, but without striking advantage, although when the amount of sugar excreted is very small the use of glycerin may cause it to disappear from the urine, at least in its usual form. It has been thought to retard emaciation in this disease. Prof. Semmola of Naples, inveighing against both the stimulant and the anti-pyretic treatment of *typhoid fever*, urgently advises in their stead the repeated administration of small doses of glycerin in water acidulated with citric or tartaric acid (*Bull. de therap.*, civ. 481), apparently not perceiving that this method is essentially an expectant treatment. Glycerin is an eligible adjunct to castor-oil. It is said that a teaspoonful of each mixed together will act as a laxative. Its medicinal virtues depend almost entirely upon its having no tendency to evaporate and to its undergoing no change by exposure to the air. Hence it may be advantageously used in all cases in which oil has from time immemorial been employed, and, owing to its solubility in water, with more effect. Thus it has been applied with good results to the rectum in *dysentery*, to the pharynx, to the larynx, trachea, and bronchia (by atomization and inhalation) in various diseases of these parts exciting *cough* and spasm or causing their obstruction. In a woman suffering from *hæmorrhoids* it was observed that while she was taking glycerin for diabetes she obtained great relief from the hæmorrhoidal affection. In other cases a complete cure of the rectal disease was accomplished by the continued use of glycerin in the dose of 2 or 4 drachms (Gm. 8–12), taken morning and evening (Young). Several subsequent reports are equally favorable to the efficiency of this treatment, which is applicable to both blind and bleeding piles. Doubtless, the slight digestibility of the glycerin permits it to reach the rectum and act as an emollient and protective. Mixed with water or pure, according to circumstances, it forms the best solvent for hardened *cerumen* and concreted epithelial scales, and is much used for keeping the *tympanum* moist. It has been applied to the treatment of recent *wounds*, but with far less satisfactory results than are obtained by dry dressings that exclude the air. When these cannot be employed glycerin may be profitably substituted. Its affinity for moisture tends in certain cases to limit the secretion of pus by drying and constricting the secreting surface. This is strikingly the case in *leucorrhœa*. The addition of an astringent—tannic acid, for example—increases the efficiency of the glycerin, which should be applied upon a tampon of lint. A similar application may be used for *fissure of the anus* and for fissured *nipples*. For the latter, however, a mixture of compound tincture of benzoin and glycerin is preferable. *Fissured tongue* is curable by a solution of 40 grains of borax in about an ounce of glycerin and 4 ounces of water. Pure glycerin applied to *carbuncles*, *boils*, and *abscesses* is said to promote their cure, but it is unsuited for application over a large surface, owing to its affinity for the moisture of the air. It allays *itching* in most affections of the skin attended with this symptom, and hence is an appropriate ingredient of ointments and washes used in their treatment. To prevent the *laryngeal mirror* from becoming obscured by the condensation of vapor upon its surface, it has been recommended to pass lightly over it a cloth wet with glycerin. *Dryness of the mouth* from fever or any other cause may be lessened by a mixture of glycerin and water far better than by water alone.

The solvent powers of glycerin have suggested the glycerites as officinal forms of certain medicines, but many others are prescribed extemporaneously. A solution of iodide of potassium in 2 parts of glycerin, with the addition of 1 part of iodine, makes an almost caustic preparation. A solution of 1 part of iodine in 5 parts of glycerin is used as a resolvent of enlarged and indurated glands and as a revulsive over inflamed joints, abscesses, etc. 1 part of glycerin and 8 parts of sulphate of zinc form an energetic caustic. Vaccine lymph may be preserved from decomposition by mixing it with glycerin.

GLYCERITA, U. S.; GLYCERITES, GLYCERINA, Br.—GLYCERINES.

Glycerata, Glycerolata.—*Glycerines, Glycerols*, E.; *Glycérés, Glycérats, Glycérolés*, Fr.; *Glycerite, Glycerolate*, G.

This class of preparations consists mostly of solutions of 1 part of a chemical compound in 5 parts by weight of undiluted glycerin, which are readily made by trituration in the mortar. Two of the official glycerites require different manipulations, which will be noticed in the proper place. These preparations were suggested in 1854 by Cap and Garot, and soon after became favorably known and have become much used. Since the strength required in special cases is readily indicated by the physician, all glycerites except two have been dismissed from the U. S. Pharmacopœia.

GLYCERINUM ACIDI CARBOLICI, Br.—GLYCERINE OF CARBOLIC ACID.

Glyceritum acidi carbolici, U. S. 1870; *Glycerite of carbolic acid*, E.—*Glycérolé d'acide phénique, Glycérine phéniquée*, Fr.; *Phenol (Phenyl) Glycerit*, G.

Preparation.—Take of Carbolic Acid 1 ounce; Glycerin 4 fluidounces. Rub them together in a mortar until the acid is dissolved.—*Br.*

Medical Uses.—This is a convenient form for the application of carbolic acid in certain eruptions of the skin, such as scabies, prurigo, etc., in which the itching is tormenting.

GLYCERINUM ACIDI GALLICI, Br.—GLYCERINE OF GALLIC ACID.

Glyceritum acidi gallici, U. S. 1870.—*Glycerite of gallic acid*, E.; *Glycérolé d'acide gallique*, Fr.; *Gallussäure-Glycerit*, G.

Preparation.—Take of Gallic Acid 1 ounce; Glycerin 4 fluidounces. Rub them together in a mortar; then transfer the mixture to a porcelain dish and apply a gentle heat until complete solution is effected.—*Br.*

Medical Uses.—This preparation, taken internally, has the advantage over gallic acid in substance of being more readily absorbable. The dose is from 20 to 60 minims (Gm. 1.30–4.0).

GLYCERINUM ACIDI TANNICI, Br.—GLYCERINE OF TANNIC ACID.

Glyceritum acidi tannici, U. S. 1870.—*Glycerite of tannic acid (of tannin)*, E.; *Glycérolé de tannin, Glycérine tannique*, Fr.; *Tannin-Glycerol*, G.

Preparation.—Take of Tannic Acid 1 ounce; Glycerin 4 fluidounces. Rub them together in a mortar; then transfer the mixture to a porcelain dish and apply a gentle heat until complete solution is effected.—*Br.*

Medical Uses.—This glycerite is not so often used internally as that of gallic acid, but as a local application to *suppurating surfaces* of limited extent it is more efficient—*e. g.* to the nostrils in chronic *coryza* and *ozæna*, to the ear in chronic catarrh, to the throat in chronic relaxation of its mucous membrane, etc. It is a useful dressing for certain chronic but irritable cutaneous eruptions, such as *eczema*, *impetigo*, *intertrigo*, etc. Dose 15 to 60 grains (Gm. 1–4).

GLYCERINUM BORACIS, Br.—GLYCERINE OF BORAX.

Glyceritum sodii boratis, U. S. 1870.—*Glycerite of borax*, E.; *Glycérolé de borax*, Fr.; *Borax-Glycerol*, G.

Preparation.—Take of Borax, in powder, 1 ounce; Glycerin 4 fluidounces. Rub them together in a mortar until the borax is dissolved.—*Br.*

From the investigations by W. R. Dunstan referred to in another place (see GLYCERINUM), it appears that this preparation will contain some free boric acid.

Medical Uses.—In this preparation the glycerin forms a convenient substitute for the honey usually employed along with borax in *aphthous* and other ulcerative affections of the mouth, nipples, vulva, etc., but is probably less efficient. It is more suitable for *pityriasis* of the scalp.

GLYCERITUM AMYLI, U. S.—GLYCERITE OF STARCH.

Glycerinum amyli, Br.; *Unguentum glycerini*, P. G.—*Glycerine of starch*, *Glycamyl*, *Plasma*, E.; *Glycéré d'amidon*, *Glycéral simple (d'amidon)*, Fr.; *Stärke-Glycerit*, G.

Preparation.—Starch 10 parts (48 grains); Glycerin 90 parts (432 grains); to make 100 parts (480 grains). Rub them together in a mortar until they are intimately mixed. Then transfer the mixture to a porcelain capsule and apply a heat gradually raised to 140° C. (284° F.) and not exceeding 144° C. (291° F.), stirring constantly until the starch-granules are completely dissolved and a translucent jelly is formed.—U. S.

Starch 1 ounce; glycerin 10 ounces (8 fluidounces). Heat to 116° C. (240° F.).—Br. Starch 1 part; glycerin 15 parts. Heat carefully.—F. Cod.

This preparation was introduced into British pharmacy by G. F. Schacht in 1858, and soon after became known in the United States. To obtain a uniform jelly-like mass, the starch should be first rubbed into a fine powder free from lumps, then intimately mixed with the glycerin, which may be done in the porcelain capsule, thus avoiding the unavoidable loss when done in a mortar; and finally the mixture is heated until all starch-granules are ruptured and the liquid is thickened to a translucent mass free from white spots. Prepared in this manner, the glycerite must be preserved in well-stopped bottles, for in contact with the air it attracts moisture and gradually becomes soft. This tendency is entirely removed, according to W. Willmott (1879), by substituting for one-third of the glycerin an equal measure of water.

For the same purpose T. B. Groves (1867) introduced a preparation under the name of *glyceolium*, which, besides glycerin, contains fixed oil; it is made by triturating $\frac{1}{2}$ ounce of fine almond meal with 1 ounce of glycerin, and then incorporating with it 3 ounces of olive oil, gradually added. The oil may wholly or in part be replaced by volatile oil or oleoresins. The preparation is a soft semi-gelatinous paste, which admits of the further addition of powders, and when mixed gradually with water forms readily an emulsion.

Zulkowsky (1880) has shown that on heating starch to 130° C. (266° F.) the starch-granules are ruptured and the mixture becomes thick and translucent, and at a higher temperature again thinner; at 170° C. (339° F.) it is quite limpid, and at 190° C. (374° F.) the starch is converted into the soluble modification—quite readily if potato starch had been used, but more slowly with wheat or rice starch. If now cooled, the mixture becomes thicker, but not gelatinous; on being poured into water the insoluble starch will precipitate, and the soluble starch may afterward be thrown down on the addition of alcohol.

The corresponding preparation of the German Pharmacopœia contains tragacanth in place of starch, and is made by triturating powdered tragacanth 1 part with alcohol 5 parts, adding glycerin 50 parts, and heating in a steam-bath until a uniform, white, translucent mass is obtained.

GLYCÉRÉ D'EXTRAIT DE BELLADONE, F. Cod. Soften extract of belladonna 1 part with a little water, and mix with glycerite of starch 10 parts. Other narcotic extracts are used in the same proportion.

Medical Uses.—This preparation forms a transparent, unchangeable, and unirritating compound. It has been much used in ophthalmic surgery, especially when medicinal agents were to be applied to the *conjunctiva*. Ordinary ointments are still to be preferred in affections of the eyelids. It answers the purpose of a light poultice in *burns*, *erythema*, *erysipelas*, *furuncle*, *intertrigo*, and various other local inflammations of the skin.

GLYCERITUM VITELLI, U. S.—GLYCERITE OF YELK OF EGG.

Glyconinum.—*Glyconin*, E., G.; *Glyconine*, Fr.

Preparation.—Fresh Yolk of Egg 45 parts (9 oz. av.); Glycerin 55 parts (11 oz. av.); to make 100 parts (20 oz. av.). Rub the yolk of egg with the glycerin, gradually added, until they are thoroughly mixed.—U. S.

This glycerite was introduced by E. Sichel (1866), who recommended 4 parts of yolk to 5 parts of glycerin. It has the consistence of honey, and keeps unaltered for a long time if kept in stoppered bottles to prevent absorption of moisture. G. C. Close (1874) recommended it as an excellent agent for emulsifying cod-liver oil and other fats.

Medical Uses.—This preparation is a protective, and, although less emollient than glycerite of starch, may be used for many of the same purposes, and is useful in *burns*, *erythema*, *erysipelas*, *intertrigo*, and other local irritations.

GLYCYRRHIZA, U. S.—GLYCYRRHIZA.

Glycyrrhizæ radix, Br.; *Radix liquiritiæ*, P. G.; *Radix glycyrrhizæ hispanica*.—*Liquorice*- or *Licorice*-root, Spanish liquorice-root, E.; *Régliſſe*, *Bois de régliſſe*, *Bois doux*, *Racine douce*, Fr.; *Spanisches Süßholz*, *Spanische Süßholzwurzel*, G.

The root (and underground stem) of *Glycyrrhiza glabra*, Linné, s. *Liquiritia officinalis*, Moench. Woodville, *Med. Bot.*, t. 152; Bentley and Trimen, *Med. Plants*, 74.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This perennial in several well-marked varieties is indigenous to the countries on the northern and southern shores of the Mediterranean and farther east, through the Caucasus, Northern Persia, Afghanistan, and Southern Siberia, to China. The typical form, var. *typica*, *Regel et Herder*, grows wild as far east as Persia, and is cultivated in England, France, and Germany, and also to a limited extent in the United States. The stout roots penetrate deeply into the ground, while long horizontal rhizomes or runners are produced near the surface. The herbaceous overground stems are 4 to 6 feet (1.2–1.8 M.) high, and have imparipinnate leaves with oval-oblong mucronate leaflets, which are glutinous beneath, and racemes of white and purplish flowers producing brown legumes containing about four seeds. The variety *glandulifera* (Gl. *glandulifera*, *Waldstein et Kitaibel*, Gl. *hirsuta*, *Pallas*) has the leaves glandular-hairy beneath, and the legumes more or less glandular-prickly; it grows wild and is cultivated from Turkey and Hungary eastward to Turkestan. The roots and rhizomes are collected together and assorted before being brought into commerce. 11,072,095 pounds of liquorice-root were imported into the United States in 1877, and over 37,500,000 pounds in 1882.

Description.—Liquorice-root consists of long cylindrical pieces varying in thickness from $\frac{1}{4}$ to 1 inch (6–25 Mm.). It is longitudinally wrinkled, covered with a grayish-

FIG. 141.

FIG. 142.

Spanish root (rhizome).

Russian root.

Glycyrrhiza glabra: transverse section of rhizome and main root.

brown warty cork, pliable, tough, and breaks with a coarsely fibrous fracture. The transverse section shows a bark about one-sixth the diameter of the root in thickness, underneath the cork of the dull or bright grayish-yellow color of the wood, and in its inner layer radiately striate from the long, narrow, and somewhat wavy bast-wedges. The woody medullium consists of tough fibro-vascular tissue, appearing porous from the large vessels, and forming narrow wedges separated from one another by still narrower medullary rays. The rhizome has the same appearance and structure, and, in addition, a thin central pith. Liquorice-root has a peculiar odor and a strongly sweet somewhat acrid taste.

RADIX LIQUIRITLÆ MUNDATA (P. G.), s. **RUSSICA**, **RADIX GLYCYRRHIZÆ ECHINATÆ**, *Russian liquorice-root*, has been stated to be obtained from *Glycyrrhiza echinata*, Linné, which is indigenous to South-eastern Europe and farther east to Central Asia, but the root as cultivated in Western Europe, though of about the same histological structure, differs very materially in the whitish color and the more bitter and slightly sweet taste from the commercial article. There can be no doubt now that at present Russian liquorice-root is mainly, if not entirely, derived from Gl. *glandulifera*, referred to above. It consists chiefly of the main root and its branches, with few rhizomes, and is about a foot (30 Cm.) long and 1 to 4 inches (2–10 Cm.) thick, often hollow above, usually deprived of the brown corky layer, and furnished with a light grayish-yellow, thin bark covering a more porous wood, which is often fissured in the direction of the medullary rays, is softer, and breaks with a more fibrous fracture, than the preceding. It has a very sweet and somewhat bitterish taste, and yields a lighter-colored powder than the former kind. Underneath the thin corky layer is the thin, small-celled primary bark; the cells of the medullary rays are larger and radially elongated; the long, tough, and somewhat wavy bast-fibres are surrounded by cells containing a crystal of calcium oxalate and accompanied by horn-like sieve-tubes; the ducts of the wood-tissue are usually in small groups, and are large, rather thick-walled, and dotted. The parenchyma of both the medullium and bark contains much starch.

Constituents.—Robiquet (1809), Plisson (1828), and others obtained from liquorice-root starch, asparagin, albumen, a resinous oily matter, to which the slight acrid taste of the root is due, coloring matter, sugar, and *glycyrrhizin*. Roussin (1875) found the latter to be present in the root, in combination with ammonia, as *glycyrrhizate of ammo-*

nium, which he obtained pure from the cold infusion, after removing the albumen by heat, by precipitating with sulphuric acid, washing the precipitate well with water, dissolving it in strong alcohol, and adding ether, whereby a blackish mass is precipitated; the clear liquid is then carefully mixed with small quantities of alcoholic solution of ammonia. The precipitate is yellowish, very light, and its hot aqueous solution on cooling forms a jelly-like mass, and on evaporation leaves glycyrrhizin in brittle, translucent, shining scales. Prepared by the same process, with the exception of the final treatment with ammonia, it was found by Gorup-Besanez (1861) to have the composition $C_{24}H_{36}O_9$; to be soluble in alcohol, ether, and hot water, and on boiling with dilute acids; to be split into glucose and a bitter resinous substance named *glycyrretin*. Habermann (1880) gives to glycyrrhizin or *glycyrrhizic acid* the formula $C_{44}H_{68}NO_{18}$, and states that by heating with diluted sulphuric acid it is decomposed into glycyrretin, $C_{32}H_{47}NO_4$, and parasaccharic acid, $C_6H_{10}O_5$, the latter yielding amorphous salts, and the former being a white crystalline powder insoluble in water, alkalies, and ether, easily soluble in alcohol, glacial acetic acid, and strong sulphuric acid, fusible at $200^\circ C.$, and not yielding any paraoxybenzoic acid with fusing potassa, as had been stated by Weselski and Benedict (1876). In purifying ammoniacal glycyrrhizin the amorphous bitter principle *glycyrramarin*, $C_{36}H_{57}NO_{13}$, was obtained, soluble in ether-alcohol, and a resin soluble in glacial acetic acid and yielding paraoxybenzoic acid, $C_7H_6O_3$, on melting it together with potassa.

Allied Drugs.—*ABRUS PRECATORIUS*, Linné, or *Indian liquorice* (see page 1).

ONONIS SPINOSA, Linné, *Radix ononidis*, *P. G.*—Rest-harrow, *E.*: Bugrane, Bougrane, *Fr.*; Haubechel, *G.*—This is a perennial herb common in sandy soil in Europe. The root, which is the part employed, is about 2 feet (30–60 Cm.) long, $\frac{2}{3}$ to $\frac{5}{8}$ inch (1–2 Cm.) thick, little branched, many headed, tough-woody, and mostly curved and of a flattened and twisted appearance. It has a deeply-wrinkled, dark gray-brown, thin bark and an irregular whitish, tough, fibrous medullium with numerous medullary rays. It has a faint odor resembling that of liquorice-root, and a mucilaginous, sweetish afterward bitterish, and disagreeable taste. It was analyzed by Reinsch (1842) and Hlasiwetz (1855). *Ononin*, $C_{30}H_{34}O_{13}$, is a crystalline, colorless, and tasteless glucoside slightly soluble in boiling water, more so in alcohol. *Onocerin*, $C_{12}H_{20}O$, is crystalline, fusible, colorless, and tasteless. Reinsch's *ononid* is considered by Hlasiwetz to be altered glycyrrhizin; like the latter, it is precipitated by acids from its aqueous solutions.

Pharmaceutical Preparations.—*SYRUPUS GLYCYRRHIZÆ*, *Syr. liquiritiæ*, *P. G.*—Syrup of liquorice-root, *E.*—Macerate for 12 hours 20 parts of peeled liquorice-root with ammonia-water 10 parts and water 100 parts, express, heat to boiling, evaporate to 10 parts, and add alcohol 10 parts, filter after 12 hours, and add sufficient simple syrup to make 100 parts.—*P. G.* A syrup of the same strength will be obtained by mixing 2 parts of fluid extract of liquorice-root with 8 parts of simple syrup.

PASTA GLYCYRRHIZÆ (*s. LIQUIRITLE*). Macerate 1 part of cut liquorice-root in 20 parts of water for 12 hours, strain and filter; add 10 parts of water, 15 of gum-arabic, and 9 of sugar; dissolve, strain, and heat, removing the scum; then evaporate until on cooling it will form a translucent mass, which is cut into suitable pieces. The French Codex recognizes a *Pâte de réglisse noire* made with extract of liquorice and sugar each 5 parts, gum-arabic 10 parts, and water 33 parts; and a *Pâte de réglisse brune*, made with 100 parts of extract of liquorice, 1500 parts of gum-arabic, 1000 of sugar, 2500 of water, and 1 part extract of opium. The finished paste will weigh 3000 parts.

Off. Prep.—Confectio terebinthinæ, *Br.*; Decoct. sarsaparillæ (*sarsæ*) comp., Extract. glycyrrhizæ (*purum*), *U. S.*, *Br.*; Extract. glycyrrh. fluid., Extract. sarsaparillæ comp. fluid., *U. S.*; Infusum lini comp., *Br.*; Massa (Pilula) hydrargyri, Pil. ferri iodidi, Pulv. glycyrrhizæ comp., *U. S.*, *Br.*; Syrup. sarsaparillæ comp., Tinct. rhei dulcis, *U. S.*

Medical Action and Uses.—Liquorice-root is demulcent and laxative, and locally is slightly stimulant; it is supposed to promote the secretions of the congested mucous membrane of the air-passages. The infusion is a useful drink in *febrile catarrhal affections*, especially those attended with much thirst, and in febrile and irritative disorders of the *bowels* and *urinary organs*. In these cases it is usually prepared with flaxseed, rice, barley, or gum-water. It is said that an infusion of liquorice-root may be used by diabetic patients without aggravating their disease. Liquorice-root is an ingredient of the very excellent laxative which is now official as the compound powder of glycyrrhiza. It is also used to correct the acid or bitter flavor of certain medicines, such as quinia, colocynth, aloes, quassia, seneka, mezereon, guaiacum, and sal-ammoniac, but for this purpose the extracts are more convenient.

It is recorded that some children who chewed the roots of “glycine” in mistake for Spanish liquorice-root presented symptoms of gastric inflammation, general collapse, and somnolence (*Med. News and Abstract*, May, 1881, p. 308).

Abrus precatorius furnishes the seeds which are treated of elsewhere (page 1); its "root has been used in the place of liquorice, for which, in our opinion, it is a very bad substitute" (Flückiger and Hanbury). *Ononis spinosa* is credited with possessing diuretic properties, and is used in decoction, either alone or as a vehicle, in the treatment of *dropsy*. The same preparation is employed as a gargle for sore throat and as a wash for ulcers of the gums and other parts (Cazin).

GLYCYRRHIZINUM AMMONIATUM, U. S.—AMMONIATED GLYCYRRHIZIN.

Glycyrrhizinum ammoniacale, *Glycyrrhizine ammoniacale*, Fr.; *Ammoniak-Glycyrrhizin*, G.

Preparation.—Glycyrrhiza, in No. 20 powder, 100 parts (20 oz. av.); Water, Water of Ammonia, Sulphuric Acid, each a sufficient quantity. Mix 95 parts (19 oz. av. or 18 fluidounces) of water with 5 parts (1 oz. av. or 1 fluidounce) of water of ammonia, and, having moistened the powder with the mixture, macerate for 24 hours. Then pack it moderately in a cylindrical percolator, and gradually pour water upon it until 500 parts (100 oz. av. or 6 pints) of percolate are obtained. Add to the percolate, slowly and while stirring, a sufficient quantity of sulphuric acid as long as a precipitate is produced. Collect this on a strainer, wash it with cold water, redissolve it in water with the aid of water of ammonia, filter if necessary, and again add sulphuric acid as long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of water of ammonia previously diluted with an equal volume of water, and spread the clear solution upon plates of glass, so that on drying the product may be obtained in scales.—U. S.

This is Roussin's process (see GLYCYRRHIZA), as modified by Appenzeller (1876), who noticed that a considerably larger quantity, somewhat darker in color, is obtained by exhausting the root with ammonia-water, and that the scales have a more pleasant taste if liquorice-root deprived of the brown corky layer be used. Commercial extract of liquorice yields a still darker and less pleasant product. The cold percolate, if not too strongly alkaline, when heated to boiling deposits most of the albumen; this and other impurities are removed by again dissolving the precipitated glycyrrhizic acid in ammonia and reprecipitating it by an acid before its ammoniacal solution is finally evaporated and sealed. The yield is about 10 per cent.

Properties.—Ammoniated glycyrrhizin is in transparent "dark-brown or brownish-red scales, inodorous, of a very sweet taste, and soluble in water and in alcohol. The aqueous solution, when heated with potassa or soda, evolves vapor of ammonia. On supersaturating the aqueous solution with an acid a substance (glycyrrhizin) is precipitated which, when dissolved in hot water, forms a jelly on cooling. This substance, when washed with diluted alcohol and dried, appears as an amorphous yellow powder of a strong, bitter-sweet taste and an acid reaction."—U. S. The scales consist mainly of ammonium glycyrrhizate, $(\text{NH}_4)_2\text{C}_{41}\text{H}_{62}\text{NO}_{18}$, with a variable quantity of glycyramarin. They are insoluble in ether, sparingly soluble in strong alcohol, become darker colored at 100°C . (212°F .), and at a higher heat melt, being decomposed at the same time. Glycyrrhizic acid is tribasic; the taste of its alkali salts is very sweet, and in the pure state free from the characteristic after-taste of liquorice; their solutions in water foam strongly on agitation and produce voluminous precipitates with most salts of the heavy metals. On igniting ammoniated glycyrrhizin not more than a trace of ash should be left behind.

Medical Uses.—The superiority of this preparation over the fluid extract of liquorice is not apparent. Possibly it may be useful in the dry stage of inflammation of the respiratory mucous membrane.

GNAPHALIUM.—LIFE-EVERLASTING.

Pied de chat, *Immortelle*, Fr.; *Katzenpfötchen*, *Immerschön*, G.

The flowers and flowering herb of different species of *Gnaphalium* and allied genera.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—GNAPHALIUM POLYCEPHALUM, *Linné*, grows in fields and woods of North America. It is a woolly annual, with lanceolate nearly entire leaves, and with the numerous ovate and obovate flower-heads in dense corymbose clusters terminating the branches; the involucrel scales are dry, scarious, and whitish, the tubular florets yellowish. The plant is quite fragrant, and has a bitterish and aromatic taste. On drying, the loss in weight of the flowering-tops amounts to about 65 per cent.

GNAPH. MARGARITACEUM, *Linné*, s. *Antennaria margaritacea*, *R. Brown*, grows in similar localities with the preceding, chiefly northward, and has larger, roundish-ovate heads, which are of a pearly whiteness and slight odor.

GNAPH. (HELICHRYSUM, De Candolle) ARENARIUM, *Linné*, grows in Europe and Asia. The heads are globular-oblong, $\frac{1}{8}$ inch (4 Mm.) long, of a lemon- or orange-yellow color and agreeable odor.

GNAPH. DIOICUM, *Linné*, s. *Antennaria dioica*, *Gaertner*, is indigenous to Europe. The barren flower-heads are hemispherical and whitish, the fertile ones more top-shaped and reddish or purplish. The species is very closely related to *Antennaria plantaginifolia*, *Hooker*, which is common in North America, where it is known as *mouse-ear*.

Constituents.—These plants appear to contain a little volatile oil and bitter principle.

Medical Action and Uses.—In Europe an infusion of the leaves and flowers of several species of *Gnaphalium*, which have, when chewed, an agreeable aromatic and slightly bitter and astringent taste, is used in chronic *bronchitis* and *diarrhoea* and in poultices to unhealthy *ulcers*. All the species are employed under similar circumstances. They may be given in an infusion made with half an ounce of the plant to a pint of water (Gm. 16 in Gm. 500).

GOSSYPHII RADICIS CORTEX, U. S.—COTTONROOT-BARK.

Écorce de la racine de cotonnier, Fr.; *Baumwoll-Wurzelrinde*, G.

The bark of the root of *Gossypium herbaceum* and of other species of *Gossypium*. *Bentley and Trimen, Med. Plants*, 37.

Nat. Ord.—Malvaceæ.

Origin.—The different species of *Gossypium* are indigenous to the tropical and sub-tropical countries of Asia and Africa, and have been cultivated from a very early period, whereby many characteristic varieties have been produced. They are herbaceous or shrubby plants or small trees, with three- to five-lobed leaves and showy axillary flowers, having a three-leaved involucre, a cup-shaped calyx, five petals, numerous stamens, and producing a three- to five-celled capsule, which opens by as many valves; the numerous seeds are densely covered with long woolly hairs. *Bentley and Trimen* refer the Sea Island cotton to *Goss. barbadense*, *Linné*, and to this the following as synonyms: *G. vitifolium*, *Lamarck*, *G. peruvianum*, *De Candolle*, *G. punctatum*, *Schumacher et Thonning*, *G. acuminatum*, *Rochburgh*, *G. religiosum*, *Parlatore*, non *Linné*. According to A. W. Chapman, the long-staple or Sea Island cotton cultivated in the United States is referred to *Goss. nigrum*, *Haworth*, and the short-staple or upland cotton to *Goss. album*, *Haw.* The seeds of *Goss. religiosum*, *Linné*, are invested with a yellow wool. Cottonroot is conical, nearly simple or little branched, hard and woody, and covered with a thin bark, which is officinal. *Goss. arboreum*, *Linné*, is cultivated in some tropical countries for cotton.

Description.—Cottonroot-bark is in bands or quilled pieces $\frac{2}{5}$ to $\frac{1}{2}$ inch (1–2 Mm.) thick, covered with a brownish-yellow, satiny, very thin cork, by the abrasion of which irregular dull brownish-orange patches appear. The cork forms slight longitudinal ridges, which are often confluent into elongated meshes and marked with black circular dots or short transverse lines. The inner surface is whitish or reddish-white, of a nearly silky lustre, and finely striate in a longitudinal direction by the thin medullary rays. The bast-fibres are long and tough, arranged in tangential rows, and are separated without difficulty in very thin layers. The bark breaks with difficulty in a transverse direction, but is readily torn longitudinally. It is without odor and without taste, with the exception of a very slight acidity and faint astringency. It bears a pretty close resemblance to meze-reon-bark, except in color and taste.

Constituents.—The bark contains *starch*, and when fresh, according to W. A. Taylor (1876), a *chromogene* which dissolves in alcohol with a pale-yellow color, gradually changing to a bright brownish-red. The same change takes place on keeping the bark for some time, which then yields a red tincture with alcohol. This substance was examined by Prof. Wayne (1872) and W. C. Staehle (1875), who regard it as of a resinous nature. The latter obtained about 8 per cent. of this substance, which is soluble in 14 parts of alcohol, 15 of chloroform, 23 of ether, and 122 of benzol; also in alkalies, from which solutions it is again precipitated by acids. The potassa solution diluted with water is of a sage-green tint. *Glucose* was likewise observed, and the aqueous solution of the alcoholic extract contained a principle which gave a purplish-black precipitate

with ferric chloride. C. C. Drueding (1877) obtained also a yellow resin soluble in petroleum benzin, fixed oil, little tannin, and 6 per cent. of ash.

Substitutions.—In 1875 a false cottonroot-bark, evidently obtained from the root of a tree, was found in the market; it was $\frac{1}{4}$ to $\frac{1}{2}$ inch (3 to 6 Mm.) thick, pale-brown to rust-brown in color, covered with a soft fissured cork, inodorous, and of a slight astringent afterward bitterish and acrid taste, and yielded with alcohol a brown tincture. Its origin has not been ascertained.

Off. Prep.—*Extractum gossypii radicis fluidum, U. S.*

Medical Action and Uses.—The only virtue of cottonroot-bark consists in its action upon the uterine system. It is reputed to have long been used by the female negroes of the Southern States for producing abortion. There appears to be little doubt that it acts like ergot upon the uterus, and that it displays its virtues in *dysmenorrhœa* and scanty menstruation, and particularly in *suppression of the menses* produced by cold. It is generally used in a decoction, prepared by boiling 4 ounces (Gm. 128) of the bark in 2 pints of water, to the reduction of one-half. Of this a wine-glassful is given every 20 or 30 minutes as an *oxytocic*. The fluid extract, which is official, is a more convenient form of the medicine, and may be prescribed in the dose of from 30 to 60 minims (Gm. 2–4). A tea made from the fresh leaves of the cotton-plant is used in Jamaica as a *galactagogue* (*Med. Times and Gaz.*, Feb. 1880, p. 194). It is true that experiments performed on frogs and rabbits by Dr. Martin (*Amer. Jour. of Med. Sci.*, Jan. 1882, p. 82), so far from indicating any action that would explain the facts just mentioned, only denote a narcotic and paralyzing operation. It is sufficient to remark that the results of such physiological experiments by no means invalidate those of clinical experience. Cotton-seed tea is a mucilaginous liquid which forms an appropriate drink in *dysentery*. The seeds have also been recommended as galactagogue, but the evidence of their value in this respect is insufficient.

GOSSYPIMUM, U. S., Br.—COTTON.

Bombyx, Lana (Lanugo, s. Pili) gossypii.—Cotton-wool, E.; Coton, Fr.; Baumwolle, G.

The hairs of the seed of various species of GOSSYPIMUM (see above).

Gossypium, Br., is carded cotton; Gossypium, U. S., is cotton deprived of fat.

Description.—Cotton consists of soft, narrow-filiform, thin-walled, simple cells, which are about $\frac{1}{2}$ to $1\frac{1}{2}$ inches (12 to 38 Mm.) long, and appear under the microscope as flattened hollow and twisted bands, which are slightly thickened at the edges, finely and spirally striate, and nearly cylindrical at the apex. Its specific gravity was by Schulmeister (1877) ascertained to be 1.707, while Kopp had previously determined it 1.27, and Grasi 1.979. It is without odor or taste, not readily moistened with water, insoluble in the ordinary solvents, but soluble in ammoniacal solution of oxide of copper, and is colored blue by solution of zinc chloride and iodine, but not by solution of iodine. It consists of nearly pure cellulose, and yields with nitric acid an explosive nitro-compound (see PAROXYLON) which is used in preparing collodion.

FIG. 143.

Cotton fibres.

GOSSYPIMUM DEPURATUM, P. G., GOSS. PURIFICATUM.—Purified cotton, Absorbent cotton, E.; Coton absorbant, Fr.; Gereinigte Baumwolle, G.—The cotton-hairs are so thoroughly impregnated with fat that this cannot be removed by simple solvents. F. L. Slocum (1881) found the following process effectual: Boil carded cotton for half an hour

with a 5 per cent. solution of caustic potassa or soda; wash thoroughly to remove all soap; express and immerse the cotton in a 5 per cent. solution of chlorinated lime for 15 or 20 minutes; again wash, first with water; then dip into water acidulated with hydrochloric acid, and thoroughly wash with water; express, and again boil for 15 or 20 minutes in a 5 per cent. solution of alkali, wash well with water, acidulated water, and water; express and dry quickly. By boiling once with alkali the cotton becomes somewhat absorbent, but the whole of the fat is not removed until it has been boiled a second time with alkali. The loss by this process is about 7 per cent., and represents mainly fat.

“Purified cotton should be perfectly free from all perceptible impurities, and on combustion should not leave more than 0.8 per cent. of ash. When thrown upon water it should immediately absorb the latter and sink, and the water should not acquire either an

acid or an alkaline reaction."—*U. S.* By the absorption of water the hairs of the purified cotton distend and become more cylindrical, losing their band-like appearance. The untwisting of the flattened tubes of cotton filaments by caustic soda was noticed by Mr. Mercer (1867); dyed in this condition, the color becomes deeper and more durable and the fabric stronger; the process was called *Mercerizing*.

Pharmaceutical Preparations.—**SALICYLIC** (*Salicylated*) **COTTON.** According to Bruns (1878), cotton should be impregnated with 5 and with 10 per cent. of salicylic acid. 50 or 100 (Gms. of salicylic acid and 10 or 20 (Gms. each of castor oil and resin are dissolved in 4 liters of alcohol, and 1 Kgm. of clean absorbent cotton is immersed in the solution and dried.

BENZOIC COTTON is made by the same processes, substituting benzoic acid for salicylic acid; the addition of a small quantity of glycerin to the alcohol serves to fix these acids more permanently to the cotton.

IODOFORM COTTON is made in a similar manner, using an ethereal solution of iodoform.

HÆMOSTATIC COTTON is absorbent cotton impregnated with Monsel's solution or with a mixture of ferric chloride and alum.

CHLORINATED COTTON is made by Pavesi (1880) by suspending cotton slightly dampened with glycerin over a mixture of chlorinated lime, water, and sulphuric acid.

Surgical Uses.—Cotton has long been employed as a dressing for *burns, scalds, blisters, excoriations, erysipelas*, and similar inflammations. If the burn, scald, or blister is superficial, there is no better dressing for it. No other application more speedily and completely allays the pain of the injury. Even when the tissue of the skin is more deeply interested the dressing is unsurpassed. It should consist of very thin layers of carded cotton, successively applied and secured by a bandage, and should not be removed until the cure is complete. Cotton impregnated with carbolic, boracic, salicylic, and benzoic acids, iodine, iodoform, etc., has sometimes been employed. (For details see Woakes, *Practitioner*, xxv. 47.) The fibre has been used as a substitute for lint, and also for sponge, after being thoroughly freed from the unctuous matter which in its natural condition renders cotton inapt for absorbing the secretions. As a dressing for *surgical wounds* cotton is said to be one of the most perfect preventives of *purulent infection*, as well as of prolonged suppuration, if it is properly applied in the manner described above. Washed, or absorbent, cotton is especially applicable to this purpose, and is still more efficient if it has been washed in carbolic acid water. Vaginal pessaries have been made of carded cotton, chiefly for cases of *uterine displacement* in which instruments or harder materials cannot be tolerated. They are so shaped as to fill the upper part of the vagina, and usually are rendered somewhat firmer by holding in their centre a bent rod of gutta-percha. They require, of course, daily or frequent removal; to obviate which difficulty they have sometimes been dipped into a solution of caoutchouc, which gives them a thin, and for a time impermeable, coating. Absorbent cotton, medicated variously as above, is a convenient substance for introducing into the ears and nostrils.

GRANATUM, *U. S.*—POMEGRANATE.

Granati radice cortex, *U. S.* 1870, Br.; *Cortex granati*, P. G.—*Bark of pomegranate-root*, E.; *Ecorce de racine de grenadier (de balaustier)*, Fr.; *Granatrinde*, *Granatwurzelrinde*, G.

The bark of the root of Punica Granatum, *Linné*. Steph. and Church, *Med. Bot.*, plate 57; Woodville, *Med. Bot.*, 190; Bentley and Trimen, *Med. Plants*, 113.

Nat. Ord.—Granataceæ (Myrtaceæ, Granatææ).

Origin.—The pomegranate is indigenous to South-western Asia from Northern India to Palestine; it has been cultivated from remote antiquity, and is now met with in all subtropical countries. It is a shrub or small tree about 20 feet (6 M.) high, with lanceolate or oblong, pointed, entire, and shining leaves, bearing one to three large crimson-colored flowers in the axils of the upper leaves, and producing a depressed globose fruit of the size of an orange, irregularly divided by a transverse dissepiment into two unequal parts, the lower and smaller of which is about three-celled and the upper five- to nine-celled. The numerous seeds are oblong, irregularly angular from pressure, each invested with a fleshy pink-colored translucent coating. The bark of the root (and trunk) is alone recognized by the pharmacopœias, but the flowers and the rind of the fruit and the sweet acidulous seed-coating are likewise used.

Description.—The bark of pomegranate-root is met with in commerce in curved pieces or quills 2 to 4 inches (5–10 Cm.) long and $\frac{1}{2}$ inch (1–2 Mm.) thick, which are externally of a brownish-gray color, marked with longitudinal or reticulate corky ridges, or irregular warts, and conchoidal depressions; the inner surface is smooth, finely striate, of a grayish- or reddish-yellow color, frequently with fragments of the whitish wood adhering. It breaks with a short, granular fracture, which is of a greenish-yellow hue and not perceptibly radiate in the inner layer; it has no odor and a purely astringent scarcely bitter taste. The trunk-bark, which is usually found in the commercial article, and is admitted by the German Pharmacopœia, is externally of a more yellowish-gray hue, is more regularly marked with corky ridges, has no conchoidal depressions upon the outer surface, and is frequently covered with blackish lichens, which are wanting on the root-bark. Both barks consist mainly of the bast-layer, and this is destitute of bast-fibres, but contains a number of scattered, thick-walled stone-cells, and consists of tangential rows of parenchyma-cells, which contain starch and tannin, and alternate with rows of crystal-cells containing calcium oxalate; the medullary rays are very numerous and delicate; the layer of primary bark is thin, and is covered with a thin layer of cork.

FIG. 144.

Punica Granatum: root-bark, transverse section, magnified 40 diameters.

Constituents.—The principal constituent is tannin, of which Wackenroder (1824) found about 22 per cent., and which was recognized as peculiar by Stenhouse (1843). By fractional precipitation of the decoction with lead acetate, Ramdohr (1867) obtained some gallotannic acid, which could be converted into gallic acid, and *punico-tannic acid*, $C_{20}H_{16}O_{13}$, which is insoluble in alcohol and ether, reduces silver and alkaline copper solutions, and precipitates gelatin, tartar emetic, and ferric salts, the latter black. When boiled with dilute acids it is split into sugar and *ellagic acid*, $C_{14}H_6O_8$. Stenhouse did not succeed in obtaining indications of the presence of gallic acid. Boutron-Charlard and Guillemette (1835) isolated *mammit*, which Latour de Trie (1830) had named *granatin*, and Guiart (1831) *granato-mammit*. Cenedella (1835) obtained also sugar and mucilaginous and pectin compounds. Tanret (1878) announced the discovery in the root-bark and stem-bark of an alkaloid, which, in honor of Pelletier, he proposed to call *pelletierine*; it is obtained by mixing the bark with milk of lime, displacing with water, and exhausting the percolate with chloroform. Thus obtained, it is colorless, oily, aromatic, and very soluble in water, alcohol, ether, and chloroform; it precipitates the salts of most metals, and unites with acids to form crystallizable salts. 4 parts of the alkaloid were obtained from 1000 parts of the bark. Shortly afterward Tanret proved that it was a mixture of three liquid and one solid alkaloid, which may be separated by fractional treatment with sodium bicarbonate. Pelletierine, $C_8H_{15}NO$, has the spec. grav. .988 at 0° C. (32° F.), boils at 125° C. (257° F.), dissolves its own weight of water, is soluble in 20 parts of water, and shows a left rotation to polarized light. *Isopelletierine* has the same composition and properties, but is optically inactive, and its sulphate is deliquescent. *Methylpelletierine* requires 25 parts of water for solution, boils at 215° C. (419° F.), is dextrogyre, and its salts are very hygroscopic. *Pseudopelletierine*, $C_9H_{15}NO$, crystallizes from ether or chloroform in long prisms, melts at 46° C. (114° F.), boils at 246° C. (475° F.), and is easily soluble.

Adulterations and Substitutions.—The bark of boxwood has an exfoliating corky layer, a yellowish-brown color, and a sweetish-bitter taste; its infusion is not affected by ferric salts. *Barberry-bark* is readily distinguished by the bright yellow color of its tissue. (See BERBERIS, p. 314.) Both these barks are free from tannin. The infusion of pomegranate-bark in 100 parts of cold water has a yellowish color, and yields with lime-water a red flocculent precipitate, and with ferric chloride a dark-blue or blue-black color.

Off. Prep.—Decoctum granati radices, Br.

Allied Drug.—GRANATI FRUCTUS CORTEX U. S. 1870; Cortex granatorum (s. malicorii), Peri-

carpium granati.—Pomegranate-rind, Pomegranate-bark, *E.*; Écorce de grenade, Cuir de pomme de grenadier, *Fr.*; Granatenschalen, *G.*—Pomegranate-rind forms irregular curved fragments, which are about 1 line (2 Mm.) thick, externally somewhat tubercular and rough, of a brownish color with a yellowish or reddish tint, internally of a lighter color, marked with meshes indicating the depressions caused by the seeds. Some of the pieces are crowned by the thick, tubular, six- to nine-toothed persistent calyx, enclosing the remains of the style and numerous stamens. They break with a short granular fracture, are nearly devoid of odor, and possess a strongly astringent taste. Examined by Reuss, pomegranate-rind was found to contain about 28 per cent. tannin, 21 extractive, and 34 gummy matter. Bowman (1869) obtained 23.8 per cent. of tannin, which gives with ferric salts a blue-black precipitate. Flückiger obtained 5.9 per cent. of ash, calculated for the rind dried at 100° C. (212° F.), also some sugar.

FIG. 145.

Fruit of *Punica Granatum*, and longitudinal section.

Medical Action and Uses.—The bark of the root has long been celebrated as an efficient *tæniacuge* and *tæniacide*. Its specific operation upon the system is manifested by giddiness, dimness of vision, drowsiness, faintness, numbness of the limbs, and even convulsions. The bark is most efficient when fresh. It is best administered in a decoction prepared as follows: Take 2 ounces (Gm. 64) of the fresh bark, hashed, and let it soak over night in 1½ pints (Gm. 750) of water, and then by gently boiling reduce it to a pint. Strain off the liquor, expressing the grounds, and give it lukewarm in three doses, at intervals of an hour, before the patient has broken his fast. If the first dose is vomited, the others should still be administered, and will generally be retained. No purgative or other treatment need precede or follow; it is, however, more prudent to administer an ounce of castor oil as soon as the gurgling and colic provoked by the decoction begin to appear. Bettelheim used a strong decoction made with 10 ounces of the root-bark and 2 pints of water, of which from ½ pint to a pint was injected through an œsophageal tube into the patient's stomach. This method, which is claimed to be very prompt and efficient in its action, is certainly as barbarous as it is superfluous. The bark of the trunk and of the branches of medium size has recently been shown to equal the bark of the root in medicinal virtues. Indeed, according to some reports (Berenger-Féraud), it is more efficient than the bark of the root in expelling the unarmed *tænia*. It may be administered in the same manner as the latter.

It has been suggested that the superiority of fresh over dried pomegranate-bark is due to the evaporation from the latter of a portion of its pelletierine; but if such were the reason, it would be difficult to understand why the most efficient preparation of the bark is that which has been subjected to prolonged boiling. Recent observations (1879) seem, however, to render it probable that this alkaloid exists in combination with tannic acid.

The body termed pelletierine is said to be composed of several which differ in the degree, and even the nature, of their action. It exerts a paralyzing action upon leeches, frogs, and rabbits, and in the last-named animals the paralysis begins in the hinder limbs, and thence extends to the fore legs, the ears, the neck, the thorax, and the heart, in the order named. It also appears to cause dilatation of the capillaries, as may be seen by the ophthalmoscope in man when under its influence.

Medicinal doses of pelletierine have caused giddiness, with, according to some, slowing of the pulse, but, according to others, the heart is unaffected; there are mistiness before the eyes, cramps in the legs and arms, formication in the fingers and toes, and sometimes nausea and vomiting. It does not tend to purge, and thus, although a *tæniacide*, it is not a *tæniacuge*. Of the four alkaloids and their compounds said to exist in pomegranate-bark, the most active are pelletierine and isopelletierine in the form of tannates.

Pelletierine was first used, in the form of a sulphate, as a *tæniacide* in 1878, but soon afterward the tannate was employed in the dose of about 7 grains (Gm. 0.45). This quantity was given originally in divided doses, but later in a single dose, preceded and followed by a draught of water at short intervals, the patient remaining quiet and recumbent to repress nausea. At the end of about 2 hours a purgative was administered. Dujardin-Beaumetz prescribes a mixture of 5 grains of the sulphate in a solution containing 14 grains of tannin (Gm. 0.30 in Gm. 0.90). It is given on an empty stomach, and followed by an ounce of compound tincture of jalap (Gm. 32). After comparing the results given by the sulphate and the tannate of pelletierine, the superiority of

the latter became manifest. As a purgative, castor oil at first was used in the dose of an ounce, but, owing to the slowness of its action, which allowed the tæniæ to recover if not killed, brisker cathartics were preferred, as the sulphates of sodium or magnesium or jalap, or the infusion of senna with the addition of the saline medicine or jalap. The "black draught," or compound infusion of senna, is very suitable for this purpose. It is desirable that the patient should diet very strictly for 1 day, taking only a moderate amount of milk in the evening, and on the following morning the medicine should be administered as above indicated. His stools should be received in a vessel filled with warm water, to facilitate the passage of the worm without breaking. Generally, it is discharged in the form of a knotted mass.

Pomegranate-rind is an astringent, and, although possessed of some anthelmintic virtues, is chiefly employed in a gargle for relaxed states of the *fauces* and in the treatment of chronic *diarrhæa*, *leucorrhæa*, passive *hæmorrhages*, and cancerous and other *ulcers* of the uterus and rectum. The *dose* in powder is from 20–30 grains (Gm. 1.30–2.00); a decoction prepared with an ounce of the rind and a pint of water (Gm. 32 to Gm. 500) may be given in the dose of a fluidounce.

GRATIOLA.—HEDGE-HYSSOP.

Herba gratiolæ.—*Gratiolæ*, Fr.; *Gnadenkraut*, *Gottesgnadenkraut*, G.

Gratiola officinalis, Linné.

Nat. Ord.—Scrophulariaceæ.

Description.—The stem grows from a creeping scaly rhizome to the height of 6 to 12 inches (15 to 30 Cm.), has opposite, sessile, lanceolate, finely serrate, three-nerved, smooth, pale-green leaves, and solitary axillary whitish or reddish two-lipped flowers, with yellow hairs in the tube. The plant is inodorous and has a very bitter somewhat acrid taste.

Constituents.—E. Marchand (1845) obtained the white crystalline bitter principle *gratiolin*, which is little soluble in water and ether. Walz afterward (1852, etc.) proved it to be a glucoside, splitting under the influence of acids into sugar, amorphous *gratiolaretin*, and scaly *gratioletin*. Walz also isolated the reddish amorphous bitter principle *gratiosolin*, which is soluble in water and alcohol, and is likewise a glucoside. *Gratioloic acid* crystallizes in white scales of a fatty odor.

Pharmaceutical Preparation.—EXTRACTUM GRATIOLÆ is the inspissated juice of the plant freed from mucilaginous matter by mixing with alcohol.

Physiological Action.—Experiments upon animals and observations upon man show that *gratiola* is a powerful local irritant, and that when taken internally it causes retching, vomiting, colic, purging, even bloody stools, and inflammation of the stomach and bowels, especially of the rectum. Given by enema, it has occasioned so much pelvic irritation as to excite nymphomania, probably in predisposed persons. In one such case it is reported to have been fatal. In smaller (not purgative) doses it is said to be diuretic.

Medical Uses.—The chief, if not the only, use to which *gratiola* is applied in medicine is the treatment of *dropsy* by hydragogue purgation, as jalap, colocynth, and elaterium are employed. As it tends only to remove the dropsical effusion, and not its organic causes in the kidneys, heart, liver, etc., the main point to be regarded is that the effects of the medicine should not be so violent as to cause the patient's collapse. Like other drastics, *gratiola* has been employed in the treatment of insane *melancholy* and *mania*, and also to expel *intestinal worms*, remove *jaundice*, cure *amenorrhæa*, etc. To remove ascarides the infusion has been used as an enema, prepared with half a drachm of the root in half a pint of water (Gm. 2 in Gm. 250). As a drastic purgative the *dose* of the root may be stated at from 10 to 30 grains (Gm. 0.60–2.0).

GRINDELIA, U. S.—GRINDELIA.

Grindelia, Fr.; *Grindelienkraut*, G.

The leaves and flowering-tops of *Grindelia robusta*, Nuttall.

Nat. Ord.—Compositæ, Asteroideæ.

Description.—The genus *Grindelia* consists of herbaceous or suffruticose perennials which are indigenous to the western part of North America and to Mexico. They are characterized by their heads being many-flowered; the ray-florets yellow, ligulate, and pistillate; the disk-florets yellow, tubular, five-toothed, and perfect; the involucre hem-

ispherical, with the scales imbricated in many rows, often with squarrose tips; the receptacle flat and alveolate; and the akenes smooth and crowned with a pappus consisting of a few rigid deciduous awns.

The officinal plant is a polymorphous species, very smooth, pale, usually stout; the leaves are 1 or 2 inches (25 or 50 Mm.) long, brittle when dry, vary from broadly spatulate or oblong to lanceolate, are sessile, the upper ones often clasping, with a heart-shaped base; obtuse at the apex, more or less sharply serrate on the margin, nearly smooth or bearing scattered glandular hairs of a pale-green color, finely dotted, and the upper surface sometimes covered with patches of a glossy resin. The involucre is about $\frac{1}{2}$ inch (12 Mm.) broad, and near the tips of the scales beset with short, flattish, many-celled glands. The akenes are from one- to three-toothed at the apex, and have two or three, rarely five, awns for the pappus. The odor is balsamic, the taste pungently aromatic and bitter. The variety *latifolia* is the robust and broad-leaved form, the leaves being often 3 to 4 inches (7 to 10 Cm.) long. The variety *angustifolia* has rather fleshy and narrower leaves, the upper ones being nearly entire, and all narrowed at the base. The variety (?) *rigida* is more glutinous, the leaves rigid and coriaceous, some of them sharply serrate. All these plants have the tips of the involucreal scales at length rigidly spreading. The plant is common along the Pacific coast and inland on the mountains.

Allied Species.—*GR. HIRSTULA*, *Hooker et Arnott*, is pubescent or tomentose, the stem often reddish or purplish, the leaves varying between spatulate, oblong, and lanceolate, the upper ones clasping. It is met with along the coast northward to Puget Sound.

GR. GLUTINOSA, *Dunal*, is said to be introduced in sandy ground near the coast of California. It is glabrous, has the leaves rounded at the apex, the involucreal scales with short tips, and the pappus of five to eight rigid awns, with thin serrulate edges.

GR. SQUARROSA, *Dunal*, which is not recognized as a distinct species in the flora of California, is found from Arctic America southward to California, Texas, and Nebraska, and is very common on the Plains. It is glabrous and viscidly resinous, the leaves rather rigid, glaucous, and punctate, varying between spatulate-lanceolate and oblong, the upper ones sessile, partly clasping, rather obtuse, and finely toothed, the involucreal scales with very long, reflexed, squarrose, subulate points.

These plants resemble the former in odor and taste, and appear to be indiscriminately collected, more particularly the last one.

Constituents.—As far as may be judged from the sensible properties, these species contain volatile oil, a bitter principle, and resin, the latter not unfrequently coating the involucre and leaves, rendering them glutinous; hence the name *gum-plant* commonly applied to them. The principles mentioned seem to be deserving of a thorough investigation.

Off. Prep.—*Extractum grindeliæ fluidum*, *U. S.*

Medical Action and Uses.—*Grindelia* has a persistent acrid and bitter taste, and excites the secretion of saliva. It is said to reduce the respiration-rate, to stimulate the brain and the spinal cord, and subsequently to produce a tendency to repose or sleep, with impaired power of the legs. In experiments on frogs it appeared to arrest breathing and to cause engorgement of the heart. It increases the secretion of urine and irritates the kidneys. The herb of this plant is reported to be useful in *whooping cough* and *bronchitis*, and of singular efficacy in *asthma*. We have been informed of several cases occurring in aged persons in which half a teaspoonful of the fluid extract afforded almost instantaneous relief. It does not, however, prevent the return of the paroxysms, nor can it at all be depended upon for relieving them when they are actually present. It has been used with alleged advantage in *catarrh* of the bladder and of the uterus, as a dressing for *burns* and *blisters*, and to allay the pain of *herpes zoster*. The dose for a child two years old is stated to be 10 drops (Gm. 0.60) of the fluid extract every 2 hours. It is added that no unpleasant symptoms have been observed after large doses. It is alleged that the tincture or fluid extract of *G. squarrosa* has been used topically with advantage in cases of *poisoning* by *Rhus toxicodendron*.

GUAIACI LIGNUM, *U. S.*, *Br.*—GUAIACUM-WOOD.

Lignum guajacæ, *P. G.*; *Lignum sanctum* (vel *benedictum*, vel *vita*).—*Lignum vitæ*, *E.*; *Bois de gayac* (de *guaiac*), *Fr.*; *Guajakholz*, *Pockholz*, *Franzosenholz*, *G.*

The heart-wood of *Guaiacum officinale*, *Linneé*, and of *Guaiacum sanctum*, *Linneé*. *Steph. and Church, Med. Bot.*, plate 90; *Bentley and Trimen, Med. Plants*, 41.

Nat. Ord.—*Zygophyllacæ*.

Origin.—These species are indigenous to the West Indian islands and to the northern

coast of South America; the second extends also to Southern Florida. The former is about 40 feet (12 M.) high, has evergreen pinnate leaves, with two, rarely three, pairs of smooth oval and obtuse leaflets, blue flowers, and two-celled obcordate capsules, each cell containing one black seed. *G. sanctum* is smaller, has leaves with four or five pairs of oblong mucronulate leaflets, and a winged four- or five-celled fruit with red seeds. The wood of both species consists of heavy dark-colored heart-wood, surrounded by a yellowish zone of sap-wood, which is generally relatively broader in the second species. Guaiac-wood became known in Europe early in the sixteenth century.

Description.—The heart-wood is of a brown color, turning olive-green on exposure, and is composed of alternately darker and lighter zones, which form incomplete circles and resemble annual rings, the tissue being well filled with resin. The central pith is quite indistinct; the medullary rays are very fine, the vessels scattered. The wood is very heavy, of specific gravity 1.3, hard, tenacious, and splitting very irregularly, caused by the much-interwoven wood-bundles. In the shops it is usually seen in the form of raspings and shavings, which should be free or nearly so from the lighter sap-wood. Guaiacum-wood has a slight aromatic odor, which is more apparent on warming or rubbing it, and a somewhat acrid taste. The shavings acquire a dark blue-green color on being moistened with nitric acid or other oxidizing agents.

Constituents.—The wood contains from 20 to 25 per cent. of resin, which is the most important constituent, and yields about 3 to 4 per cent. of aqueous extract. Frémy and Urbain (1881) found in the wood, besides 21 per cent. of cellulose, also 36 per cent. of *vasculose*, which is not soluble in ammoniacal copper solution, even after treatment with sulphuric acid.

Allied Species.—(*GUAIAECUM ANGUSTIFOLIUM*, Englemann, s. *Portiera angustifolia*, Gray, is a small tree of Southern Texas and Mexico, with a hard, heavy, and irregularly splitting wood of a yellowish-brown color, and used like the preceding.

Pharmaceutical Preparations.—SPECIES LIGNORUM, P. G.; SPECIES AD DECOCTUM LIGNORUM.—Wood tea. *E.*; Espèces (Bois) sudorifiques. *Fr.*; Holzthee. *G.*—Guaiacum-wood 5 parts; rest-harrow-root (ononis), 3 parts; peeled liquorice-root, sassafras-root, each 1 part; cut and mix.—*P. G.* Guaiac-wood, sassafras-root, sarsaparilla, and china-root, of each equal parts.—*F. Cod.*

GUAIACI RESINA, *U. S.*, *Br.*—GUAIAAC.

Resina guajaci, *Guaiacum*.—*Guaiacum resin*, *E.*; *Résine de gaïac*, *Fr.*; *Guajakharz*, *Guajak*, *G.*

The resin of the wood of *Guaiacum officinale*, *Linné*. (See *GUAIACI LIGNUM*.)

Origin.—The resin is obtained partly as a natural exudation or from incisions, partly by setting fire to a billet of the wood which has been grooved or pierced lengthwise on the side, the resin as it melts running from the opening.

Description.—The resin is in separate or agglutinated tears, varying in size from $\frac{1}{4}$ to 1 inch (6 to 25 Mm.) in diameter, or more generally in irregular masses, intermixed with fragments of wood and bark. It is of a greenish- or reddish-brown color, brittle, breaks with a somewhat conchoidal fracture having a glassy lustre, and is transparent in thin splinters. It yields a whitish powder which turns rapidly green on exposure to the air, has the specific gravity 1.2, fuses at about 85° C. (185° F.), emitting an agreeable odor, suggesting that of vanilla, and at a higher temperature gives off irritating vapors. Its taste is not strong, but distinctly acrid. The resin is soluble in caustic potassa and in nearly all the ordinary solvents for resins, except carbon bisulphide, benzol, and oil of turpentine; it is nearly insoluble in benzol and fats. The solutions, as well as the powder, are colored green or blue by nitric acid, chlorine, ferric chloride, and other oxidizing agents; the same color is produced by ozone and upon the inner surface of the paring of a raw potato. Guaiacum resin should be soluble in alcohol, leaving but a slight residue; sometimes it is very impure, containing as much as 16 per cent. of wood and bark. Its alcoholic solution has a slight acid reaction, and when dissolved in solution of potassa or soda it is reprecipitated on the addition of an acid.

Constituents.—On boiling guaiac resin with milk of lime *guaiacic acid* and *guaiac-yellow* are dissolved. If the residue is treated with hot alcohol, the tincture evaporated, and this residue dissolved in hot solution of caustic soda specific gravity 1.3, the sodium

salt of *guaiaretic acid* will crystallize on cooling, and the mother-liquor contains *guaiaconic acid* and *beta resin*, which after the removal of the alkali are separated by ether, in which the former only is soluble.

Guaiacic acid, $C_{12}H_{16}O_6$, was discovered in guaiac-wood by Thierry (1841), and is present in very minute quantity; it crystallizes in white needles and is sublimable and soluble in water, alcohol, and ether. *Guaiaretic acid*, $C_{20}H_{26}O_4$, discovered by Hlasiwetz (1859), crystallizes in warts and scales, is of a faint vanilla odor, and is soluble in alcohol, ether, chloroform, benzol, etc., and sparingly soluble in cold water and ammonia. *Guaiaconic acid*, $C_{38}H_{46}O_{10}$, discovered by Hadelich (1862), is light-brown, amorphous, insoluble in water, benzol, and carbon bisulphide, easily soluble in alcohol, ether, chloroform, and acetic acid; it acquires a transient blue color with oxidizing agents. Hadelich's *guaiac-beta resin* is a red-brown powder; his *guaiac-yellow*, which was first noticed by Pelletier, has a bitter taste, forms pale-yellow octahedra, and dissolves in oil of vitriol with a handsome blue color and in alkaline liquids with a deep-yellow color. Hadelich obtained about 70 per cent. of guaiaconic acid, 10 per cent. each of guaiaretic acid and beta resin, and nearly 4 per cent. of gum, the remainder being the other constituents, including some impurities and 0.8 per cent. of ash.

On subjecting guaiaretic acid to dry distillation, a thick yellow oil is obtained, consisting of *guaiacol*, $C_7H_8O_2$, the methylic ether of pyrocatechin, which is a colorless oil of agreeable odor, and forms with alkalies crystallizable salts; *guaiacene*, C_8H_8O , which is thin, oily, of a bitter almond odor and hot aromatic taste; and *pyroguaiacin* (*pyroguaiacol*), $C_{10}H_{12}O_3$, which crystallizes in inodorous and tasteless scales. H. Wiesner (1880) gives to the last-named compound the formula $C_{18}H_{18}O_3$, and states that while it dissolves in sulphuric acid with a dark-blue color, its alcoholic solution gives no reaction with ferric chloride, contrary to the observation of Hlasiwetz, who found it to be colored green by ferric chloride, and regarded the similar reaction of the officinal resin to be probably due to this compound. By dry distillation guaiac resin yields *creosol*, $C_8H_{10}O_2$, in addition to the decomposition-product mentioned; it and the allied guaiacol are colored green by caustic alkalies and blue by alkaline earths; both have been observed in creasote. (See page 514.) On distilling pyroguaiacin with zinc-dust, Wiesner obtained *guaiene*, $C_{12}H_{12}$, in bluish fluorescing scales. Boetseh (1880) observed this to melt near $98^\circ C.$ ($208.4^\circ F.$), and to dissolve in sulphuric acid with a green color. He obtained this compound also from the resin by treatment with zinc-dust, and in addition thereto 50 per cent. of creosol and 30 per cent. of toluol, xylols, and pseudocumol. Hirschsohn (1877) found guaiaicum resin to be free from cinnamic acid, umbelliferon, sulphur, and nitrogenated compounds.

Tests.—In addition to the properties mentioned above, Hirschsohn states that guaiacum resin should yield to petroleum benzin not more than 2 to 4 per cent. of its weight; colophony and damar dissolve to the extent of 77 to 90 per cent. The so-called *Peruvian guaiac resin*, of undetermined origin, has an odor resembling a mixture of rue and anise, and about 42 per cent. of it is soluble in benzin. The alcoholic solution of guaiacum resin is precipitated by lead acetate (difference from carana resin), and with potassa solution gives a precipitate easily soluble in excess of the alkali (difference from colophony).

Off. Prep.—Mistura guaiaci, *Br.*; Pilul. antimon. comp. (hydrarg. subchlor. comp.), *U. S.*, *Br.*; Tinctura guaiaci, *U. S.*; Tinct. guaiaci ammoniata, *U. S.*, *Br.*

Physiological Action.—Guaiac was for a long time regarded as a diaphoretic, because the syphilitic patients to whom its decoction was largely administered, and who were placed in conditions favorable to diaphoresis, sweated abundantly. It appears to be a stimulant whose action may be artificially directed to the skin. In excessive and concentrated doses it excites a burning pain in the throat and stomach, vomiting, purging, palpitation, congestion of the head, confusion of mind, and giddiness. These effects are produced by the decoction of the wood, and cannot, therefore, be due to the resin, which is insoluble in water, but which from its strong taste and smell can hardly be without action upon the economy, and is probably, like its congeners, a vascular stimulant.

Medical Uses.—Guaiac is most renowned for the cure of constitutional *syphilis*, and the records of its use during nearly three hundred years were accepted as true until the scepticism of the nineteenth century condemned it. The vain and frivolous methods of employing it which prevailed among modern physicians fully account for its want of success in their hands. While it was in vogue the treatment by it was serious. The patient was obliged to observe a very strict regimen, to drink enormous quantities of a stronger and of a weaker decoction of the wood, to live upon a very sparing and simple diet,

and in every manner to promote perspiration. The question of its efficiency has, however, possessed a very subordinate interest since the introduction of iodide of potassium. Like other vascular stimulants, guaiac resin has been found efficient in promoting menstruation in all atonic conditions of the uterine system, and hence in *dysmenorrhœa* as well as in *amenorrhœa* of that origin. For the same reason, doubtless, it is a valuable remedy for chronic muscular *rheumatism*. For these purposes the ammoniated tincture is to be preferred. In simple *tonsillitis* and in *diphtheria* it is alleged to be very efficacious, but the former disease gets well spontaneously, and the evidence of the value of guaiac in the latter is inconclusive.

Guaiacum-wood is prescribed only in decoction (*Pharm.* 1870), simple or compound, of which the latter is the more efficient. The resin may be given in doses of from 10 to 30 grains (Gm. 0.60–2.0). The guaiac mixture (*Br. P.*) is a convenient form for its administration.

When the red coloring matter of the blood is brought into contact first with tincture of guaiac, and then with peroxide of hydrogen, the guaiac is instantly turned blue. On testing suspected stains in this manner "it will be safe to say that if there is no bluing of the guaiac resin in the presence of the peroxide, the mark or stain is not owing to blood" (Taylor).

GUANO.—GUANO.

Origin.—Guano consists of the partially-decomposed excrements of the penguin and other sea-birds, which congregate in large numbers on the barren and uninhabited islands on the western coast of South America, in Western Africa, and Australia. It is principally exported from the islands off the coast of Peru and Bolivia.

Description.—It is in the form of crystalline or amorphous masses, or more frequently of an irregular powder, having a grayish or pale-brown color and an offensive, usually ammoniacal, odor. Its spec. grav. is about 1.64; its reaction is mostly alkaline, though occasionally acid. It contains hygroscopic water varying between 6 and 20 per cent., which is expelled by the heat of a water-bath; when exposed to a higher temperature it blackens and burns, leaving a white ash varying in amount between 25 and 38 per cent.

Constituents.—Guano contains, besides the moisture, 25 to 52 per cent. of organic matter and ammonium salts, 19 to 42 per cent. of tricalcic phosphate, and 5 to 15 per cent. of alkaline salts; the nitrogen varies in amount from 7 to 15 per cent. The organic constituents of guano are chiefly *uric acid*, *ammonium urate*, and various oxalates. The chief inorganic constituents are phosphates of calcium, magnesium, and the alkalis, some sulphates, chlorides, and a very little sand; occasionally also ammonium carbonate. B. Unger (1845) discovered in guano the alkaloid *guanine*, $C_5H_5N_5O$, which has since been proved to exist also in the pancreatic juice of mammals; it forms a white crystalline powder which is insoluble in water, alcohol, ether, and ammonia, but soluble in acids and in potassa solution.

In estimating the value of guano as a manure the amount of the following constituents, besides moisture and ash, is determined: ready-formed ammonia (present as ammonium salts), latent ammonia (generated in the soil from nitrogenous compounds), uric acid, and phosphates.

Medical Action and Uses.—Under the singular delusion that the ammonia in guano possesses some special mode of action different from that of officinal ammonium compounds this substance was mixed with potter's clay and used as a dressing for several diseases of the skin, and afterward in baths and lotions. But it speedily exhibited the irritating effects proper to the salts of ammonia in common use, and is now quite abandoned. It will hardly be believed that this bird-dung should have been introduced into a syrup and administered internally.

GUARANA, U. S.—GUARANA.

Pasta guarana.—*Guarana*, Fr., G.

A paste prepared from the crushed and ground seeds of *Paullinia sorbilis*, *Martius*. Bentley and Trimen, *Med. Plants*, 67.

Nat. Ord.—Sapindacæ.

Origin.—*Paullinia sorbilis* is a climbing shrub with pinnate leaves composed of five

oval-oblong toothed leaflets, small flowers in narrow spicate panicles, and pyriform beaked capsules containing one to three shiny blackish-brown subglobular seeds. It is indigenous to the northern and western provinces of Brazil.

Preparation.—The dry seeds are powdered, moistened by water or by exposure to the dew, and then kneaded into a kind of stiff paste, which is formed into globular or cylindrical masses; these are well dried near a fire or by exposure to the sun.

Description.—Guarana is met with in subglobular, cylindrical, or elliptic cakes which have an uneven surface, are hard, of a reddish-brown color, somewhat lighter internally, and breaking with an uneven, slightly glossy fracture, showing angular fragments of seeds with a brittle purplish-brown or blackish testa and with thick whitish cotyledons. It has a peculiar slight chocolate-like odor and an astringent and bitter taste.

Constituents.—Martius found guarana to contain starch, gum, a greenish fat, tannin which precipitates iron salts dark-green, and a crystalline substance, *guaranine*, which was afterward proved to be identical with *caffeine* (p. 342) by Martius and by Berthemet and Dechastelus (1840). The latter obtained 4 per cent., Stenhouse 5.07 per cent., and Feemster (1882) between 3.9 and 5 per cent., of *caffeine*. Saponin and volatile oil are likewise present in guarana. The alkaloid is best obtained, according to Dr. F. V. Greene (1877), by Prof. Wayne's process, by prolonged boiling with litharge; and Mr. Feemster found it of advantage to add near the end of the process a few drops of lead subacetate, which facilitates the settling of the insoluble matter. The tannin, *paullinitannic acid*, was shown by Dr. Greene to give precipitates with ferric salts (green, brown), gelatin, most alkaloidal salts, and barium salts, to give no precipitate with tartar emetic or copper sulphate, and to reduce salts of silver and gold.

Off. Prep.—*Extractum guaranæ fluidum*, *U. S.*

Allied Plant.—*Paullinia Cupana*, *Kunth*, which grows near the Orinoco River, has flattish, convex seeds; these are mixed with cassava and water and subjected to fermentation, yielding a saffron-yellow liquid which is used as a beverage.

Physiological Action.—Among the conclusions drawn from his experiments by Mantegazza are these: that guarana, by its tannin, tends to retard putrefaction; that, like *caffeine*, it first excites frogs, then impairs their power of co-ordination, and ultimately throws them into spasms; and that it also slows the action of their hearts. In various warm-blooded animals it produced similar effects, but it rendered the rabbit only somewhat dull and languid, and in dogs occasioned a sort of intoxication and eccentricity of movement. According to the same authority, in man it gives rise to gaiety, restlessness, increased quickness of perception and mental activity, wakefulness, a slight fall in the pulse-rate, impaired appetite, and vesical irritation. Like others, he includes guarana in the same category with maté, coffee, and tea, giving it the first place as a promoter of cerebral action. In curious contrast to these definite and striking results are those of Dr. Macdowall of West Riding Insane Asylum, Eng. He experimented upon himself and two male attendants, and it soon became evident to him that even in very large doses its effect upon the body in a state of health is almost, if not quite, inappreciable. It does not even cause constipation. In large doses it appears to dispel drowsiness after a late dinner, just as tea and coffee do.

Medical Uses.—The curative powers of this agent when first introduced appeared to be not less wonderful than those of many other new remedies. It was a specific for diarrhoea and dysentery, gonorrhoea, leucorrhoea, and passive hæmorrhages, was lauded as a stomachic tonic, and was even put forward as remarkably efficacious in lumbago. Of all these virtues of the drug none survive, and the only affection in which it continues to be found useful is one which its congeners, tea (and especially green tea) and coffee, have never lost the reputation of relieving—*headache*. The particular forms of headache in which it is useful are the nervous sick headache which recurs frequently in the same person, and especially in females at the menstrual periods, and that which follows a debauch, when the head throbs and the eyes are bloodshot. Like the other more popular remedies, guarana gradually loses its power over these attacks, and even appears to render them more frequent and severe. It may be administered in substance in the dose of from 15 to 60 grains (Gm. 1–4) in powder, but in this form it is repulsive, and the doses mentioned are better given in infusion. The most efficient preparation is, however, the alcoholic extract, dissolved in alcohol to form a tincture in the proportion of 1 part to 30. From 2 to 5 grains (Gm. 0.10–0.30) of the extract may be given at a dose. A fluid extract, which is officinal, and a syrup, have been made, and are convenient forms for administration.

GUTTA-PERCHA, U. S., Br. Add.—GUTTA-PERCHA.

Gutta-percha depurata, *Gutta-taban*, *Gummi plasticum*.—*Gutta-percha*, Fr., G.

The concrete exudation, obtained by incisions, of *Isonandra* (*Dichopsis*, *Bentley*) *Gutta*, *Hooker*. *Loudon's Journal of Botany*, 1848; *Bentley and Trimen, Med. Plants*, 167.

Nat. Ord.—Sapotaceæ.

Origin and Preparation.—The *taban* is a stately tree, 40 to 60 feet (12–18 M.) high, with few branches, with evergreen oblong or obovate, entire, glossy, and underneath brownish-yellow scaly leaves, and small white flowers aggregated in little clusters near the top of the branches. It is common in jungles of the Malay peninsula and of the Malayan Archipelago; it is now extinct in Singapore, having been destroyed in the collection of the juice. To obtain the gutta-percha the tree is felled and circular incisions are made through the bark at distances of 6 to 12 inches (15–30 Cm.) along the whole trunk, from which the milky juice slowly exudes and hardens on exposure. The yield from one tree is stated to be from 6 to 10 pounds; others claim a yield of over 20 pounds. Several other sapotaceous trees of the genera *Dichopsis*, *Payena*, and *Ceratophorus* yield similar products.

Description.—*Gutta-percha* is grayish or yellowish, frequently with red-brown streaks from fragments of bark and other impurities. It is hard and rather leathery or horny, in thin pieces somewhat flexible, is readily cut with the knife, between 45° and 60° C. (113° to 140° F.) sufficiently soft to be rolled into sheets, quite plastic at 65° C. (149° F.), and very soft at the temperature of boiling water. Its specific gravity is about 0.98, but it is heavier than water after the removal of all air-cavities (*Payen*). It is insoluble in water, alcohol, acids, alkalies, and fixed oils, dissolves in boiling ether, chloroform, benzol, coal-tar oils, carbon bisulphide, and oil of turpentine; on evaporating these solutions it is left behind with its original properties. It is purified for dental and other purposes by agitating its solution with gypsum. If purified by treatment with water and hydrochloric acid, and then repeatedly dissolved in boiling ether and washed with cold ether and alcohol, a fine white powder is obtained of the composition $C_{20}H_{32}$, which is probably the composition of the recent juice (*Baunhauer*, 1859). It absorbs and combines with oxygen from the air, yielding white crystalline resin, *Payen's albane*, $C_{20}H_{32}O$, and yellow amorphous *fluavil*, $C_{20}H_{32}O_2$, which are contained in commercial gutta-percha sometimes to the amount of 20 per cent. Subjected to dry distillation, various gases, water, and volatile acids are obtained, and two oils, one yellow, the other red-brown, both of the composition $C_{10}H_{16}$.

Pure gutta-percha is inodorous and tasteless; ignited, it burns with a bright flame. Its mixture with caoutchouc is readily vulcanized, and after the incorporation of insoluble earthy or metallic compounds is largely used in the preparation of various instruments.

PERCHA LAMELLATA, *P. G.*—*Gutta-percha paper*—is in thin, brown, translucent sheets, which are prepared by softening gutta-percha in hot water and pressing it between rollers.

Off. Prep.—Liquor gutta-perchæ, *U. S., Br.*

Allied Products.—*Murton* (1878) describes four additional guttas:

GUTTA-SOOSOO of Perak is firmer than gutta-taban, and contains a little oil, but gutta-soosoo of Borneo is a caoutchouc.

GUTTA-RAMBONG of Perak is reddish-brown, closely resembles caoutchouc, and is probably obtained from the milk-juice of the roots of *Ficus elastica*.

GUTTA-SINGGARIP seems to be produced from a woody apocynaceous climber, and enters commerce as a soft, spongy, and wet mass.

GUTTA-PUTIH or **GUTTA-SUNDEK** comes from a species of *Dichopsis*, having shorter and broader leaves than the *taban* tree, and is whiter and more spongy than gutta-percha.

Other similar products from different species of *Ficus* and *Isonandra* are used in the Malayan islands for adulterating gutta-percha.

BALATA—in Central America called *chicle*, *tumo gum*, and *leche de popa*—is the milky exudation of *Sapota Muelleri*, *Blume*, a tree called *bully tree*, growing on the banks of the Orinoco and Amazon Rivers. It resembles gutta-percha, becomes soft at 50° C. (122° F.), melts at 150° C. (302° F.), is soluble in benzol, carbon bisulphide, and hot oil of turpentine, and partly soluble in absolute alcohol and ether. It is not acted on by alkalies or hydrochloric acid, but is decomposed by strong nitric and sulphuric acids. It has been used as an addition to plasters.

Surgical Action and Uses.—The qualities which render this substance of value in the surgical and mechanical treatment of diseases are—its flexibility when warm, its firmness at ordinary temperatures, and its solubility in menstrua which do not alter its

essential qualities. The facility with which it is bent and moulded when warm adapts it to making splints, whose size, shape, and weight can readily be changed. It has in a great degree supplanted the old and costly carved splint, to which, indeed, it is in all respects superior. Its lightness, firmness, smoothness, and unalterable character render it admirably adapted for the manufacture of syringes, specula, bougies, pessaries, stethoscopes, etc. Like collodion, the solution of gutta-percha in bisulphide of carbon or in chloroform may be used to retain the edges of incised wounds in apposition, and also as a protective of the *abraded skin* against mechanical injury or the *absorption of poisons*. In this manner it has been used as a coating for *sore nipples*. The solution in chloroform, which is officinal, is a very convenient agent for protecting portions of the skin from the air, while it exerts a slight degree of compression which is modified by the elasticity of the film formed by the dried solution. It has been used with more or less advantage in the treatment of *lepra* and *psoriasis*, to prevent pitting in *small-pox*, and to limit the efflorescence in *erysipelas*; but the results are not conclusive of its utility. Gutta-percha is also found to be a convenient vehicle with which to incorporate certain caustics, as potassa and chloride of zinc, for the purpose of limiting and mitigating their action.

GYNOCARDIA.—CHAULMUGRA.

The seed of *Gynocardia* (*Chaulmoogra*, *Roxburgh*, *Hydnocarpus*, *Lindley*) *odorata*, *R. Brown*. Bentley and Trimen, *Med. Plants*, 28.

Nat. Ord.—Bixacææ.

Origin.—The chaulmugra is a large tree of the Malayan peninsula, growing northward to Assam and westward to Sikkim. It has alternate oblong and acuminate leaves and dioecious yellowish flowers, each petal having a dark-yellow spreading scale at the base. The fruit is globular, gray, one-celled, pulpy, and many-seeded.

Description.—The seeds are irregular ovoid, about an inch (25 Mm.) long, somewhat angular, dull-gray, have a brittle testa, and contain a large embryo with a thick radicle and a pair of leafy cordate cotyledons imbedded in a brown oily albumen. The kernel has a faint, peculiar, somewhat unpleasant odor and taste.

Constituents.—By subjecting the seeds to pressure or by boiling them in water *chaulmugra oil* is obtained, which, when pure, is of a pale or golden-sherry color, melts at about 40° C. (104° F.), and on keeping frequently deposits a granular fat; that obtained by boiling is said to remain clear, and, according to Dymock, does not form a green tenacious mass on stirring 20 minims of it with 1 minim of sulphuric acid. On the contrary, when the expressed oil is thus treated a reddish-brown resin-like mass is formed around the acid. John Moss (1879) ascertained that the acid reaction of the oil is due to palmitic and gynocardic acids, and that the oil consists of glycerides of palmitic and about 11.7 per cent. of gynocardic acid, with small proportions of hypogæic and cœcinic acids. *Gynocardic acid* has a yellowish color, crystallizes readily in plates, melts at 29.5° C. (85° F.), has an acrid burning taste, is probably of the formula $C_{14}H_{24}O_2$, and gives a green color with sulphuric acid; a similar color is also produced by the same reagent with palm oil.

Allied Species.—*HYDROCARPUS VENENATA*, *Gaertner*, a large tree of Western India, has a tomentose fruit containing longitudinally striate, and on the edges rugose, seeds.

HYDROCARPUS WIGHTIANA, *Blume*, a large tree, a native of Ceylon, has a fruit of the size of a small apple and obtusely-angular seeds. The seeds of both species yield a fatty oil which is used like chaulmugra oil.

Medical Action and Uses.—Chaulmugra oil has from time immemorial been held in great esteem by the native races of India as a potent medicine in the treatment of *leprosy*, *scrofula*, *phthisis*, *syphilis*, *rheumatism*, *itch*, and various *diseases of the skin*. For the first named of these diseases it is held in the Mauritius to be a specific remedy. Of its mode of action nothing is known beyond the fact that when given in excessive doses it causes vomiting. Of its utility in leprosy we have the report of Dr. Young, who treated fifty-three cases, of which four belonged to the macular, twenty-three to the anæsthetic, fifteen to the tubercular, and eleven to mixed forms of the disease. He concluded that in the macular and in the early stage of the anæsthetic forms of leprosy chaulmugra appears to be of decided value. Several of the cases treated were complicated with bronchial affections, which were quite relieved during the treatment. The oil was given in gradually-increasing doses, beginning with 5 drops three times a day, but the good effects of the treatment were seen earlier in cases treated with the powdered seeds. A liberal milk diet seemed to be a valuable auxiliary. These results have, on

the whole, been confirmed by the later experience of competent judges. Thus, Dr. Living draws attention to the fact that leprosy (*E. græcorum*), like many other fatal diseases, is liable to long periods of comparative rest or subsidence quite apart from any special treatment. After a study of twenty cases he concludes that neither gurjun oil nor chaulmugra oil can be regarded as a specific for the disease; some cases improved under its use, but he adds, "I have never met with one well-authenticated case of complete cure under its influence" (*Times and Gazette*, Aug. 1879, p. 205). Mr. C. T. Peters found this oil useful in relieving the dyspeptic symptoms of lepers and in promoting the absorption of the leprosy tubercles (*Edinb. Med. Jour.*, xxviii. 214). It seems to form a convenient and useful local application, for its unctuous smoothness has been compared to that of goose-grease. It was employed in England (1879) in the treatment of pulmonary *phthisis*. The patients showed an unusual degree of objection to taking it on account of its nauseous odor and taste, and when mixed with cod-liver oil it became peculiarly repugnant to them. The result of the trial was altogether unfavorable (Yeo). These unfavorable results have been confirmed by subsequent observations of Murrell. "The oil has a deserved reputation in cases of *itch* and parasitic *pediculi*." In skin diseases, except, perhaps, in chronic *psoriasis* and *eczema*, this oil has proved irritating. Rheumatism and gout have been alleged (Cottle) to improve rapidly under the use of chaulmugra oil, but confirmatory evidence is wanting. It may be administered in the dose of 5 drops (Gm. 0.30) enclosed in gelatin capsules, or in an emulsion with milk, glycerin, or almond oil. The seeds, coarsely powdered, are given in pills in the dose of 5 or 6 grains (Gm. 0.30-0.40). The ointment (*Pharm. Ind.*) is used externally.

HÆMATOXYLON, U. S.—Logwood.

Hæmatoxyli lignum, Br.; *Lignum Campechianum*, *Lignum caruleum*.—*Bois de Campeche*, *Bois d'Inde*, *Bois de sang*, Fr.; *Blauholtz*, *Blutholz*, *Campechholz*, G.

The heart-wood of *Hæmatoxylin campechianum*, *Lamé*. Woodville, *Med. Bot.*, plate 17; Bentley and Trimen, *Med. Plants*, 86.

Nat. Ord.—Leguminosæ, Cæsalpineæ.

Origin.—The logwood tree is indigenous to the shores of the Gulf of Campeachy and to other parts of Central America, and has been introduced into, and perfectly naturalized in, Jamaica, St. Domingo, and other West Indian islands. It is 30 to 40 feet (9-12 M.) high, has many spreading and crooked branches, alternate leaves with four pairs of obcordate leaflets, small yellow flowers in lax racemes, and two-seeded legumes. The tree is felled when about 10 years old; the bark and light-colored sap-wood are removed, the red heart-wood alone entering commerce.

Description.—Logwood is met with in logs about 3 feet long, which consist of the heart-wood, and, from exposure, are externally of a blackish-purple or red, internally of a brown-red, color. Irregular concentric circles of darker and lighter red color, resembling annual rings, are observed upon cross-section; the vessels are distinct to the naked eye, the medullary rays very fine. The wood is heavier than water, specific gravity about 1.06, splits irregularly, has a slight agreeable odor and a sweetish and astringent taste, and imparts a deep-pink color to the saliva. In the shops it is found in the form of chips and ground into a coarse powder, upon both of which a greenish lustre (*hæmatein*) is often observed. Under the microscope the cell-walls are seen to have a red color, and the ducts and wood-fibres to be filled with a red resin-like mass, occasionally forming in the ducts crystals of a green metallic lustre.

Constituents.—Analyzed by Chevreul (1812), it was found to contain a little volatile oil, brown extractive containing tannin, fatty or resinous and glutinous matter, and a crystalline substance which he named *hæmatin*, but which is now more properly called *hæmatoxylin*. According to Erdmann (1842), it is best obtained from powdered extract of logwood by mixing it with much sand and exhausting with ether; the ether is mostly recovered by distillation, and the residue mixed with some water and crystallized, a little sulphurous acid or solution of a sulphite being added to prevent oxidation; the yield is about 12 per cent. Impure hæmatoxylin is met with in French commerce as *hæmatine*, and is used for dyeing. When pure, hæmatoxylin is $C_{16}H_{14}O_6$, and crystallizes with 1 or $3H_2O$ in colorless or pale-yellow prisms which have a strongly sweet taste of liquorice, acquire a red color on exposure to the light, are freely soluble in hot water, in alcohol, and ether, and, fused with potassa, yield pyrogallol. The aqueous solution is slightly precipitated by solution of isinglass, and produces with baryta solution, lead acetate, and copper salts white or grayish precipitates which rapidly turn blue. Ammonia dissolves

hæmatoxylin, the solution being rose-red, then purple, and finally blackish-red; the fixed alkalis produce similar solutions, and the color ultimately becomes yellowish-brown. The blackish ammonia solution contains *hæmatein-ammonia*, from which acetic acid separates *hæmatein*, $C_{16}H_{12}O_6$; this is soluble in alcohol and hot water, slightly so in ether, and forms a blackish-violet crystalline powder having a green metallic lustre. *Hæmatein-ammonia* causes, in a warm solution of a small amount of alum and with ferric chloride, deep-violet precipitates; with lead acetate, a brown one.

Off. Prep.—Decoctum hæmatoxyli, *Br.*; Extractum hæmatoxyli, *U. S., Br.*

Medical Action and Uses.—Logwood is mildly astringent and has been reputed to possess tonic virtues. Its preparations darken the feces, and sometimes turn the urine blood-red and give it a sweetish taste. They constipate less than the pure astringents. They are used to check *diarrhœa*, *hæmorrhage*, and *sweat*; their mildness renders them appropriate for infantile diarrhœa. Externally, logwood is said to display antiseptic and healing qualities in the treatment of *gangrenous* and *ill-conditioned sores*.

HAMAMELIS, *U. S.*—HAMAMELIS.

Witch-hazel, *E.*; *Hamamelis*, *Fr.*; *Hamamelis*, *Zauberhasel*, *G.*

The leaves of *Hamamelis virginica*, *Linne*, collected in autumn.

Nat. Ord.—Hamamelaceæ.

Origin.—The witch-hazel is a shrub from 6 to 10 feet (1.8–3 M.) high, growing in damp woods and thickets in Canada and the United States. It has a rather crooked stem, with a close white wood and with flexuose branches, which are covered with a smooth brown bark, the older bark being brown-gray and somewhat fissured, and internally whitish and smooth. The flowers are in clusters of three or four with an involucre of three ovate leaflets, have a four-cleft calyx and four long linear, greenish-yellow petals, and appear in September and October, the nut-like two-celled and two-beaked capsule, containing two black oily edible seeds, not ripening until September of the next year. The bark, which has been medicinally employed, has a bitter, astringent, and somewhat pungent taste.

Description.—The leaves are alternate, short-petiolate, thickish, 4 to 6 inches (10–15 Cm.) long, oval or obovate, feather-veined, wavy-toothed on the margin, slightly heart-shaped and oblique at the base, stellate-pubescent when young and nearly smooth when old; they are inodorous, and have an astringent and bitter taste.

Constituents.—H. K. Bowman (1869) ascertained the bark to contain 8.10 per cent. of tannin, which was determined by means of gelatin. The leaves have not been analyzed; they contain tannin and a bitter principle.

Off. Prep.—Extractum hamamelidis fluidum, *U. S.*

Medical Action and Uses.—The accounts published of the remedial virtues of witch-hazel seem to be as hard to accept as the popular faith in it as an infallible divining-rod. Yet through the extravagant statements concerning it there runs a thread of truth, for all the conditions it is said to relieve are those of morbid excitement, such as *inflammations*, *congestions*, and *hæmorrhages*, and even the action of the gravid uterus in threatened *miscarriage*. To the tannin it contains, and to a peculiar bitter principle, some of its alleged sedative virtues may be attributed. It was used by the American aborigines in decoction as a wash, and also in a poultice, for various local swellings and inflammations, including *hæmorrhoids* and *ophthalmia*; and when the negro slaves endeavored to produce abortion by means of cotton-root, miscarriage is said to have been prevented by the use of hamamelis. Recent observations (1882) appear to justify the use of witch-hazel to check hæmorrhage, relieve irritable and painful piles, and promote the healing of unhealthy wounds and irritable and varicose ulcers. It may be used in a decoction made with an ounce of the bark to a pint of water (Gm. 32 to Gm. 500), and given in wine-glassful *doses* every 3 or 4 hours, or oftener, according to the urgency of the case. We have known a decoction or infusion to be applied as a lotion with apparent benefit in *crusta lactea*. The fluid extract is officinal, and an ointment may be made with this extract evaporated to dryness or with the fresh bruised bark boiled in lard. The last is used for *hæmorrhoids*.

HEDEOMA, *U. S.*—HEDEOMA.

American pennyroyal, *E.*; *Herbe de pouliot américain*, *Fr.*; *Amerikanischer Polei*, *G.*

The leaves and tops of *Hedeoma* (*Melissa*, *Linne*, *Cunila*, *Willdenow*, *Ziziphora*, *Des-*

fontaines) *pulegioides*, *Persoon*. *Barton, Med. Bot.*, t. 41; *Bentley and Trimen, Med. Plants*, 200.

Nat. Ord.—*Labiatae*, *Satureieae*.

Origin.—Pennyroyal is an annual herb indigenous to North America, from Canada south through the United States. It grows in barren and sandy fields, on hills, and along the open border of woods, always in dry places.

Description.—It has an erect, obscurely quadrangular, branched, and hairy stem about 6 to 12 inches (15–30 Cm.) high; opposite, shortly-petioled, oblong-ovate, and obscurely serrate leaves, which are about $\frac{1}{2}$ inch (12 Mm.) long and glandular dotted on the lower side, and axillary cymes of about three flowers. The calyx is tubular-ovoid, hairy in the throat, and somewhat two-lipped, the upper lip divided into three lanceolate teeth, the two lower teeth subulate. The corolla is small, the tube scarcely exceeding the calyx, pale-blue with purplish spots, two-lipped, the upper lip erect and emarginate, the lower lip spreading and nearly equally three-lobed. It has two sterile and two fertile somewhat exserted stamens, a bifid style, and produces four small smooth akenes at the base of the persistent calyx. It has a strong aromatic mint-like odor and a warm and pungent taste.

FIG. 146.

Heledoma pulegioides, *Persoon*: flower and corolla, cut open; magnified.

Constituents.—Its virtues depend upon the volatile oil. (See *OLEUM HEDEOMÆ*.) Its other constituents are probably those generally found in plants of this natural order.

Allied Plants.—*MENTHA PULEGIUM*, *Linné* (s. *Pulegium vulgare*, *Miller*), the European pennyroyal, is a perennial herb found in moist sandy localities in Central and Southern Europe. It has an ascending branching stem, oval-obtuse and crenately-serrate leaves, many-flowered axillary cymes forming globular whorls, and a purplish-colored four-lobed corolla. It resembles the former in odor, while the taste is somewhat bitter and acrid.

HEDEOMA PIPERITA, *Benth.*, *Hed. Drummondii*, *Benth.*, and some other species, are found near the Rocky Mountains, and may possess similar properties.

Medical Action and Uses.—*Heledoma* is an aromatic stimulant. It may be prescribed, like other medicines of its class, to relieve flatulent colic or painful digestion, to correct the nauseating or griping operation of certain purgatives, etc. For these purposes it is less eligible than mint, anise, etc. In the form of hot infusion it is much used to dissipate the congestions tending to diarrhoea and to inflammations of the throat or bronchia, also in muscular rheumatism, etc., and, in conjunction with the hot hip- and foot-baths, to bring on retarded or suspended menstruation. An infusion made with half an ounce (Gm. 16) of the plant to a pint (Gm. 500) of water may be given in the dose of 2 fluidounces or more every hour. *Mentha pulegium* possesses similar virtues.

HELENIUM.—SNEEZEWEED.

Helenium autumnale, *Linné*. *Meehan, Native Flowers*, ii. 113.

Nat. Ord.—*Compositae*, *Senecionideae*.

Description.—The sneezeweed or sneezewort is an herbaceous perennial which is common in damp places in the United States from Maine to Florida and Texas and westward to California and Oregon. It is of a grayish-green color, nearly smooth, 3 to 5 feet (.9 to 1.5 M.) high, has a branching quadrangular, winged stem, and lanceolate-serrate leaves which are pointed above and narrowed toward the base. The flower-heads are rather large, numerous, and have the involucre scales in two rows, the outer one foliaceous and reflexed; the ray-florets are ligulate, drooping, yellow, veined, and obtusely three-toothed at the apex. It flowers in August and September. The plant has scarcely any odor and possesses a very bitter taste.

Constituents.—It was analyzed by F. J. Koch (1874). Besides the principles common to herbs, it contains malic acid and traces of tannin; the bitter taste is due to a principle which was obtained in an amorphous condition, is soluble in ether, alcohol, and boiling water, and on being boiled with dilute sulphuric acid is resolved into sugar and an amorphous bitter substance having an acid reaction.

Allied Plants.—*HEL. PARVIFLORUM*, *Nuttall*, indigenous to Georgia, has lanceolate, nearly entire, scarcely decurrent leaves, and smaller flower-heads than the preceding.

HEL. TENUIFOLIUM, Nuttall (Meehan, *Nat. Flow.*, ii. 37), has numerous linear or filiform entire leaves and small flower-heads. It is found in the Southern United States from Georgia westward to Texas, Arkansas, and Southern Kansas. The properties of these two species appear to be similar to those of the first.

Medical Action and Uses.—Common sneezewort is so called on account of the acrid qualities of its flowers and leaves, which when dried and powdered have been used as an errhine for the purpose of dissipating incipient *coryza* and relieving *headache*. *H. tenuifolium* is said to be very poisonous to animals, producing in them muscular twitchings, passing into violent convulsions, and terminating in death. In four negroes it produced spasms, with more or less delirium and loss of consciousness (Galloway).

HELIANTHEMUM.—FROSTWORT.

Herbe de heliantheme de Canada, Fr. ; *Canadisches Sonnenröschen*, G.

The herb of *Helianthemum canadense*, Michaux, s. *Cistus canadensis*, Linné.

Nat. Ord.—Cistaceæ.

Frostwort or *rock-rose* is a perennial herb indigenous to dry and rocky hills and sandy or gravelly soil of Canada and of the United States south to Florida.

Description.—The rigid slender stem is about 12 inches (30 Cm.) high, has alternate elliptic or linear lanceolate entire leaves, which are nearly an inch (25 Mm.) long and woolly beneath. The flowers are of two kinds: the earlier ones, appearing in June, are solitary, stalked, with five unequal hairy sepals, and the same number of large yellow petals, which unfold in sunshine only once. Somewhat later smaller apetalous and nearly sessile flowers make their appearance in axillary hoary clusters. The fruit is a three-valved, one-celled capsule, which is shorter than the calyx and contains few brown seeds. The herb, which varies much in habit, is inodorous and has a bitterish-astringent taste.

A closely-allied species, *Hel. corymbosum*, Michaux, is mainly distinguished by the petal-bearing and apetalous flowers being in crowded cymes near the top of the branches, the former being on elongated, filiform stalks. It grows from New Jersey southward near the coast, in similar localities with the former.

It has received the names of *frostwort* and *frostweed* from the crystals of ice which shoot from the cracked bark of the base of the stem during freezing weather in autumn.

HEL. VULGARE, Gaertner, *CISTUS HELIANTHEMUM*, Linné, indigenous to Europe, resembles the preceding and possesses similar properties.

Constituents.—Frostwort has not been analyzed. It seems to contain tannin and a bitter principle.

Medical Uses.—The bitter, astringent, and slightly aromatic taste of this plant may explain its alleged utility in *scrofula*, *diarrhoea*, and secondary *syphilis*. A strong decoction of it is apt to produce vomiting, but is employed as a gargle in *sore throat*, especially as it occurs in *scarlatina*, and also as a wash for *prurigo*. An extract is prepared which may be given in the *dose* of 2 grains (Gm. 0.12).

HELIANTHUS.—SUNFLOWER.

Helianthe, *Grand soleil*, Fr. ; *Sonnenblume*, G.

Helianthus annuus, Linné.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—The sunflower is indigenous to tropical America and cultivated in most civilized countries, in many of which it has become naturalized or grows spontaneously. It has a straight stem from 10 to 15 feet (3–4.5 M.) high, which contains a large white pith. The leaves are alternate, petiolate, 10 inches (25 Cm.) long, broadly ovate or heart-shaped, three-ribbed, serrate, and rough. The flower-heads are from 8 to 12 inches (20–30 Cm.) in diameter, with bright-yellow ligulate ray-florets and a flat brownish disk. The akenes are obovate-oblong, somewhat quadrangular, flattened, vary in color between whitish and black, are at the base embraced by the chaff, and crowned with a very deciduous pappus of two chaffy scales. On being triturated with water the kernels yield a bland emulsion.

Constituents.—Wittstein (1876) obtained from the fresh plant, deprived of the fruit, 1.9 per cent. of ash, nearly two-thirds of which were carbonate of potassium, and from the fruit between 16 and 28 per cent. of fixed oil. *Sunflower oil* is pale-yellow, limpid, bland, has the sp. gr. 0.962, and dries slowly on exposure to air; under the influence of nitrous acid it forms a soft yellow mass; with strong sulphuric acid it turns red

and brown, but is not altered by a weak acid. The kernels contain also, according to Ludwig and Kromayer, *helianthic acid*, $C_7H_8O_4$, which reacts dark-green with ferric salts, is soluble in water and alcohol, and not precipitated by gelatin or ferrocyanide of potassium. The dried pith, according to John, contains 9 per cent. of potassium nitrate.

Allied Plants.—The numerous species of this genus have yellow flowers, rough and frequently opposite leaves, and generally possess little odor. The next is occasionally cultivated for culinary purposes:

HELIANTHUS TUBEROSUS, Linné.—Jerusalem artichoke, *E.*; Topinambour, *Fr.*; Erdartischke, *G.*—Indigenous to Brazil. The tubers are thick, oblong, externally reddish, internally white, and resemble the artichoke in flavor, but are less pleasant. Examined by Braconnot, Payen, and others, they were found to contain 76 to 77 water, 14.7 sugar, mucilage, inulin, 1 to 3 per cent. albumen, etc.

ACTINOMERIS SQUARROSA, Nuttall, is a coarse-looking herb 5 to 10 feet (1.5–3 M.) high, with a winged stem, and with alternate, or sometimes opposite, oblong-lanceolate, and tapering leaves. The involucre consists of two rows of spreading or reflexed scales; the receptacle is small, hemispherical; the ray-florets, about six, are short, yellow, and neutral; the flat, broadly-winged, and two-awned akenes are partly enclosed by chaff. The plant grows in moist ground in the Middle and Western United States.

Medical Uses.—Sunflower is scarcely a medicinal agent. Its oil may be used for many of the purposes of olive oil, the seeds for fattening poultry and, after expression of the oil, for cattle, the pith of the stalk for making moxas, and the growing plant for drying damp soils on account of its remarkable power of absorbing water. The preposterous assertion has been made that the dried stems infused in whiskey cure intermittent fever. Quite possibly the alcohol of the preparation may have some such effect.

ACTINOMERIS HELIANTHOIDES, or gravel-weed, is said to be diuretic and to have been used with advantage in cases of gravel, and also in dropsy (*Therapeutic Gaz.*, Sept. 1881). The evidence in its favor is not, however, very conclusive.

HELLEBORUS.—BLACK HELLEBORE.

Radix hellebori nigri, *Radix melampodii*.—*Ellebore noir*, *Fr.*; *Schwarze Nieswurzel*, *Weihnachtswurzel*, *Winterrose*, *G.*

The rhizome, with the rootlets, of *Helleborus niger*, Linné. Woodville, *Med. Bot.*, 169; Bentley and Trimmen, *Med. Plants*, 2.

Nat. Ord.—Ranunculaceæ, Helleboræ.

Origin.—Black hellebore, also called *Christmas rose*, is a native of Europe, and is met with in mountainous woods from Southern Germany and Central France southward

FIG. 147.

Helleborus niger, Linné: transverse section of rhizome and root.

FIG. 148.

Helleborus viridis, Linné: transverse section of rhizome and root.

to Italy and eastward to Greece. It flowers in winter, from December to March. The plant is acaulescent, and has coriaceous, smooth, pedately seven- to nine-lobed leaves, and pale-green petioles and flower-stalks mottled with red; the single flowers have five large white or pinkish sepals and ten or more small greenish petals. The fruit consists of five to nine follicles, having the black shining seeds in two rows.

Description.—The rhizome, with branches, has an irregular knotty appearance, is 1 to 3 inches (25–75 Mm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–12 Mm.) thick; the branches are annulate from leaf-sheaths and terminate with a concave (or when more recent with a convex) scar. The numerous rootlets are long, but, being very brittle, are always more or less broken off in the commercial article, about $\frac{1}{10}$ inch (2.5 Mm.) thick, longitudinally wrinkled, and, like the rhizome, of a brown-black color. The transverse section of the rhizome shows a thick brownish-gray bark occupying about one-sixth of the diameter, a somewhat thicker

whitish pith, and six to ten small wedge-shaped wood-bundles placed in a circle and separated by broad medullary rays. The rootlets have a thick bark and a central slightly pentagonal or hexagonal wood. In the dry state black hellebore has scarcely any odor; its taste is sweetish, then bitterish-acrid.

In several European countries the rhizome and roots of *Helleborus viridis*, *Linné*, are official and considered to be more efficacious. They are gathered, together with the radical leaves, in the autumn or in early spring, before flowering; the leaves serve merely for identification, and are to be removed when used. The plant, which is indigenous to Central and Southern Europe and grows wild on Long Island, produces its greenish flowers in March or April, and has pedately seven-lobed radical leaves with the lobes lanceolate-acute and serrate. The rhizome is smaller, about 2 inches (5 Cm.) long and $\frac{1}{4}$ inch (6 Mm.) thick, above knotty from the numerous stem-remnants, and annulate by the leaf-scars; the numerous nearly simple rootlets are 4 inches (10 Cm.) long, brittle, and usually broken off in the commercial article. In color, odor, and taste it resembles black hellebore. The transverse section of the rhizome shows a large pith with broad branches, and a woody ring consisting of four broad and short wedges, each composed of several smaller ones. The rootlets have a thick bark and a central obtusely four-branched ligneous cord. This drug is known in Europe, and prescribed as *Radix hellebori viridis*, or *green hellebore*; it should not be confounded with *Veratrum viride*, to which the same common name is sometimes given. It is considerably higher in price than black hellebore, and not often met with in the American market.

Constituents.—The two rhizomes appear to have the same constituents. Aside from those more generally met with, like resin, gum, etc., they contain *helleborin*, $C_{36}H_{42}O_6$, discovered by Bastick (1852), and *helleborein*, $C_{26}H_{34}O_{15}$, discovered by Husemann and Marmé (1865); the latter principle is more abundant in black, the former in green, hellebore. On exhausting the concentrated tincture with hot water and filtering from the resin and oil, helleborin will crystallize; it is very poisonous, scarcely soluble in cold water, little so in ether and fixed oil, and freely soluble in alcohol and chloroform; its alcoholic solution has a burning taste, and it yields grayish amorphous and tasteless *helleboresin*, $C_{30}H_{38}O_4$, on being boiled with solution of zinc chloride. *Helleborein* is obtained from the decoction by precipitating with basic lead acetate, then with sodium sulphate, and finally with tannin; the latter precipitate is decomposed by oxide of lead, the dry mass exhausted with alcohol, the tincture concentrated and mixed with ether. It forms colorless nodules of minute needles, is readily soluble in water, less so in alcohol, and insoluble in ether, and has a sweetish taste and a poisonous action. Boiling with dilute acids converts it into sugar and greenish amorphous and tasteless *helleboretin*, $C_{11}H_{20}O_3$.

Hellebore contains no tannin; an organic acid present is probably identical with acetic acid.

Adulterations.—Black hellebore of commerce is often mixed with the rhizomes and roots of other, mainly ranunculaceous, plants, the most frequently occurring being *Aetna spicata*, *Linné*, which was formerly known as *Radix Christophoriana*, s. *Aconiti racemosi*; the rhizome has a close resemblance to *cimicifuga* (see page 118), but merely the dimensions of black hellebore; its rootlets have the woody column arranged in four rays. The rhizome of *Adonis vernalis*, *Linné*, is subconical, almost simple, tufted above, not annulated, and has brittle rootlets with a cross-shaped wood; it probably contains potassium and calcium aconitates, of which salts Linderos found (1877) the leaves to contain about 10 per cent.; but the active principle appears to be a glucoside, *adonidin*, isolated in 1882 by Cervello as a colorless, amorphous, inodorous, and very bitter substance, which is soluble in alcohol, sparingly soluble in ether and water, and precipitated from the latter solution by tannin; in its effects it is said to resemble digitalin. At one time we observed a black, forked, monocotyledonous rhizome of unknown origin offered as black hellebore.

Pharmaceutical Uses.—EXTRACTUM HELLEBORI.—Extract of black hellebore, *E.*; Extrait d'ellébore noir, *Fr.*; Nieswurzextrakt, *G.*—The drug is exhausted with alcohol and diluted alcohol (*U. S. P.* 1870), or preferably with alcohol of 60–70 per cent.; the yield is about 14 per cent.

TINCTURA HELLEBORI.—Tincture of hellebore, *E.*; Teinture d'ellébore noir, *Fr.*; Nieswurztinktur, *G.*—Black hellebore 2 troyounces; displace with diluted alcohol sufficient for obtaining 1 pint.—*U. S. P.* 1870.

Physiological Action.—Experiments on animals show that, however introduced into the system, hellebore and helleborein are violent gastro-intestinal irritants, producing

vomiting and purging, with copious bilious evacuations, and killing through exhaustion and convulsions. Helleborein acts chiefly on the nervous system as a powerful depressant. In man small and repeated doses of hellebore produce liquid alvine evacuations and increase the menstrual and hemorrhoidal flows. In larger doses it causes vomiting, colic, spasm of the throat, thirst with heat in the abdomen, exhaustion, failing pulse, dilated pupils, cold sweats, and collapse with spasms. In the fatal cases reported nothing is said of its having purged.

Medical Uses.—The reputation of this medicine rests chiefly upon the cures attributed to it of *mania* and *melancholy*, for which it was in some sort held to be a specific. Possibly it may have been useful in cases of mental disorder connected with constipation and congestion of the liver and the abdominal organs generally. Yet the form of insanity which it seems most to have benefited in modern times is acute mania with febrile excitement. Like all drastic purgatives, black hellebore is sometimes curative of *amenorrhœa* either of the congestive or the atonic form, and is often a palliative of *ascites* by removing more or less of the dropsical fluid through the bowels. For this purpose it is inferior to jalap. The *dose* of the powdered root as a purgative is from 5 to 20 grains (Gm. 0.30–1.30). A decoction may be prepared by boiling 60 grains of the bruised root in a pint (Gm. 4 in Gm. 500) of water, of which a fluidounce may be given every 2 or 3 hours until it operates. The antidotes to poisoning by black hellebore are diffusible stimulants, given after the evacuation of the poison.

Adonis vernalis acts upon the frog's heart very much like *digitalis*, producing a tonic contraction of the organ and a diminished pulse-rate (Bubnow, 1880; Cervello, 1882). Clinical observation leads to a similar conclusion, for the medicine restores its rhythm to the arrhythmical heart, rendering the pulse slower, fuller, and stronger. It augments the urinary secretion by increasing the proportion of water in it while diminishing its solid ingredients. In cardiac *dropsy* it therefore palliates all the symptoms depending upon obstruction of the heart—viz. those due to the heart itself and those occasioned by the dropsy—and measurably it has analogous effects in renal dropsy, unless the effusion is very large and the kidney lesion very general. The same is true of it in hepatic and splenic dropsy. *Adonis* is useless in functional disease of the heart. The infusion is made with from $\frac{1}{2}$ drachm to 2 drachms (Gm. 2–8) in 6 fluidounces (Gm. 150) of water. *Dose*, a tablespoonful every one, two, or three hours (Botkin, *Centralblatt f. g. Ther.*, i. 361).

HEMIDESMI RADIX, *Br.*—HEMIDESMUS-ROOT.

Indian sarsaparilla, Nunnari, E.; *Racine de hemidesmus*, Fr.; *Hemidesmus-Wurzel*, G.

The root of *Hemidesmus indicus*, *R. Brown* (*Periploca indica*, *Willdenow*; *P. emetica*, *Retzius*; *Asclepias pseudo-sarsa*, *Roxburgh*). Wight, *Icon. Plant. Ind. Orient.*, ii. p. 594; Bentley and Trimen, *Med. Plants*, 174.

Nat. Ord.—*Asclepiadaceæ*.

Origin.—This slender climbing shrub is a native of the Indian peninsula, in all parts of which it grows in uncultivated places. It has opposite entire leaves, varying between linear-lanceolate and ovate, the broadest being on the upper branches, axillary clusters of small purple flowers, long linear follicles, and numerous seeds with tufts of slender hairs.

Description.—The root is met with in pieces about 6 inches (15 Cm.) long and $\frac{1}{4}$ to $\frac{3}{5}$ inch (6–15 Mm.) thick, cylindrical, tortuous, longitudinally wrinkled, and transversely fissured, forming annulations. It is covered with a thin dark-brown corky layer, followed by a whitish mealy thin bark containing in its inner layer scattered laticiferous vessels. The cambium-line is dark, wavy, and the wood yellowish with narrow medullary rays, which are best observed in the thin roots. *Hemidesmus*-root has an agreeable odor, suggesting that of tonka, and a sweetish, slightly acid, not unpleasant taste.

Constituents.—The root contains starch, and in the suberous layer some tannin. Scott (1843) obtained a stearopten by distillation with water. Its other constituents are unknown.

Off. Prep.—*Syrupus hemidesmi*, *Br.*

Medical Action and Uses.—In India, whence it was introduced into England, this medicine has some reputation for efficacy in the constitutional disorders supposed to be benefited by sarsaparilla. But its syrup, which is also official, is, like the syrup of sarsaparilla, chiefly used as a flavoring ingredient of mixtures.

HEPATICA.—LIVERWORT.

Herbe de hépatique, Fr. ; *Edelleberkraut*, G.

The leaves of *Hepatica triloba*, *Chaix* (*Hep. nobilis*, *Moench* ; *Anemone Hepatica*, *Linneé*).

Nat. Ord.—*Ranunculaceæ*, *Anemonidææ*.

Origin.—A perennial acaulescent herb flowering in March and April, and indigenous to Europe and North America south to Georgia, growing in shady woods. The flowers are on villous scapes 4 to 6 inches (10–15 Cm.) long, and have a three-leaved involucre and six to nine petal-like blue or purplish, or sometimes white, sepals. The radical leaves are the portion used ; the loss in drying amounts to from 70 to 75 per cent.

Description.—The leaves are subcoriaceous, smooth, dark-green, and shining above, paler beneath, broadly heart-shaped or somewhat kidney-shaped in outline, and divided into three lobes, which are obtuse or rounded (*Hep. americana*, *De Candolle*) or pointed (*Hep. acutiloba*, *De Candolle*). A similar distinction is also observed in the involucral leaves, the two forms being probably mere varieties of one species, the acute-lobed preferring a northern exposure. The leaves are inodorous and have an insipid, slightly astringent, and bitterish taste.

Constituents.—As far as may be judged from the sensible properties, liverwort does not appear to contain any important characteristic principle. Mucilage, sugar, and a small amount of tannin are present.

Medical Action and Uses.—Liverwort passes for being tonic and deobstruent. It once had a transient vogue in the treatment of chronic *bronchitis* and *phthisis*. But its medicinal value is very small, and hardly entitles it to a place in the *materia medica*. It may be given freely in infusion.

HERACLEUM.—COW-PARSNIP.

Heracleum lanatum, *Linneé*.

Nat. Ord.—*Umbelliferæ*, *Orthospermæ*.

Description.—The cow-parsnip, also called *masterwort*, is a woolly perennial herb growing from 5 to 10 feet (1.5–3 M.) high in most of the northern and middle parts of the United States westward to the Pacific. The root is many-headed, fleshy, nearly simple, or composed of many thinner branches, half an inch (12 Mm.) or less in diameter, brownish-yellow externally, white internally, with a rather thick bark containing resin-cells. The leaves are large, ternately dissected, on very broad and sheathing petioles, the segments often 10 inches (25 Cm.) long, the middle one usually three-lobed. The umbels are from 12 to 15 inches (30–38 Cm.) broad, with an involucre of oblong lanceolate leaves and involucels composed of five or eight lanceolate, slender, acuminate leaves. The flowers are white. The fruit is $\frac{1}{8}$ inch (8 Mm.) long, oval, flattened on the back, broadly winged on the margin, each mericarp with five slender ribs, the lateral ones being close to the margin, and in the upper half with six clavate oil-tubes, two of which are on the commissure. All parts of it have a rank odor and a pungently acrid taste. The root, leaves, and fruit have been employed.

HERACLEUM SPHONDYLUM, *Linneé*, the cow-parsnip of Europe and Northern Asia (*Berce*, *Fausse acanthe*, *Fr.* ; *Baerenklaue*, *G.*), is a similar but smaller plant, and possesses similar properties.

Constituents.—These plants appear to contain volatile oil and resin ; their acrid principles have not been investigated.

Medical Action and Uses.—In their fresh state the leaves applied to the skin may produce vesication and have been used as counter-irritants. Some of the European species are still more irritant, and contain a juice which has been applied to *warts* as an escharotic. The American plant has been used with alleged curative effect in *epilepsy* apparently depending upon gastro-intestinal irritation. It is given both in substance and in infusion, and is thought to correct *dyspeptic* disorder. A drachm (Gm. 4) of the root or its equivalent in infusion may be taken several times a day.

HEUCHERA.—ALUM-ROOT.

Racine d'heuchère d'Amérique, Fr. ; *Amerikanische Sanikel-Wurzel*, G.

The root of *Heuchera americana*, *Linneé*.

Nat. Ord.—*Saxifragaceæ*.

Origin.—This is a perennial herbaceous plant, with a tuft of orbicular-heart-shaped, slightly lobed, and crenately-toothed hairy leaves, and glandular hairy scapes about 2 feet (60 Cm.) high, bearing loose panicles of small flowers with short, white, narrow petals and exserted stamens and styles. It is common in rich woodlands of the United States from the New England States west to Wisconsin and the Mississippi and south to Georgia. It flowers in June, and the root is probably best collected in September.

Description.—The root is about 6 inches (15 Cm.) long and about $\frac{1}{2}$ inch (12 Mm.) thick, with several short cylindrical heads terminating with a concave scar, tapering, and somewhat branched below, and beset with some thin radicles. In its fresh state it is fleshy; when dry, irregularly shrivelled, tuberculate, the brittle fibres usually broken off. It is externally of a purplish-brown color, has a thin bark and a thick, fleshy medullium of a pale-reddish, sometimes brownish, tint, and breaks with a short somewhat spongy or granular, not fibrous, fracture, often showing internal cavities. It is inodorous, and has a strongly astringent, slightly bitterish taste. The rootlets agree with the main root in color and taste, but have a thick bark and thin, spongy centre.

Constituents.—The root has not been fully analyzed. H. K. Bowman (1869) found it to contain from 18 to 20 per cent. of tannin.

It is not unlikely that the root of *Heuchera villosa*, Michx., and probably other species, may possess virtues similar to those of the official.

Medical Action and Uses.—Alum-root, as its name implies, is astringent. In decoction it is sometimes used in domestic medicine as a remedy for *diarrhœa* and *menorrhœgia*, as a mouth-wash for *aphthæ*, and as an application to *ulcers*, *hemorrhoids*, etc. It may be used in decoction.

HIERACIUM.—HAWKWEED.

Epervière, Fr.; *Habichtskraut*, G.

Nat. Ord.—Compositæ, Cichoraceæ.

Description.—The following species have been used:

HIERACIUM VENOSUM, Linné.—Rattlesnake-weed.—It is a perennial herb, common in dry woods and plains of North America, with oblong-obovate, purple-veined, entire, and scarcely petiolate radical leaves about 2 inches (5 Cm.) long, and with a naked or one-leaved smooth scape about 18 inches (45 Cm.) long, bearing a loose paniculate corymb of yellow flower-heads, which have slender peduncles, a nearly cylindrical involucre, and linear akenes with a tawny, fragile, bristly pappus. The plant is inodorous, and has a somewhat bitter and acrid taste.

HIER. GRONOVII, Linné, likewise a North American species and growing in similar localities, has a wand-like simple stem which is leafy and hairy below. The leaves are petiolate, lance- or obovate-oblong, the peduncles slender, and, like the involucre, glandular-pilose. The akenes are tapering at the summit. This and the next species are sometimes used for toothache.

HIER. SCABRUM, Linné.—It is stouter than the preceding, rough-hairy, more branched, the involucre glandular-hirsute and the akenes not taper-pointed.

HIER. PILOSELLA, Linné.—Piloselle, Oreille de souris, Fr.; Mäuseöhrchen, G.—A European plant, with white hairy leaves about an inch (25 Mm.) long, and a hairy, naked, or one-leaved scape. Its taste is bitter and astringent.

HIER. MURORUM, Linné.—Pulmonaire des Français, Fr.; Gelbes Lungenkraut, G.—It has ovate, pale-green, sometimes spotted radical leaves, and a hairy, few-leaved stem about 3 feet (90 Cm.) high, bearing several yellow flower-heads. Its taste is slightly bitter and astringent. It has been used as a vulnerary and in pectoral complaints.

Medical Uses.—Although hawkweed has been used in several diseases, such as scrofula and chronic catarrh, its chief claim to notice rests on its reputed power of curing the bites of venomous snakes. The late Dr. Griffith of Philadelphia, in his *Medical Botany*, relates the following: "Some years ago a person brought a collection of rattlesnakes to this city, and professed to be in possession of a certain cure for the symptoms arising from their bite, which he offered to divulge for a moderate compensation. This being paid him, he suffered himself to be bitten several times, and after the poisonous effects had displayed themselves was completely relieved by taking a few ounces of the decoction of a plant which was identified as *Hieracium venosum*. The same snake was suffered to bite a small puppy, which died from the poison in about 5 hours. These experiments were made in the presence of a number of distinguished medical and scientific persons."

HIPPOCASTANUM.—HORSE-CHESTNUT BARK.

Cortex hippocastani, *Cortex castaneæ equinæ*.—Écorce de marronnier (*chataignier*) d'Inde, Fr.; *Roskastanienrinde*, G.

From *Æsculus Hippocastanum*, *Linneé*, s. *Hippocastanum vulgare*, *Gaertner*.

Nat. Ord.—Sapindaceæ, Hippocastaneæ.

Origin.—The horse-chestnut is a well-known stately tree which is a native of Persia and Northern India, became known in Europe in the latter half of the sixteenth century, and is at present cultivated as an ornamental tree and grows spontaneously in many countries of the temperate and subtropical zones. The bark of the smaller branches is the part employed. The seeds, which have a bitter and acrid taste, contain a large quantity of starch, which may be obtained pure by prolonged washing with water.

Description.—The bark is thin, externally of a gray color, has some small scattered warts, and shows opposite leaf-scars, which have the lower rounded margin marked with five or seven small warts. The inner surface is smooth and whitish, the internal color brownish. The inner bark is rather tough, breaks with a fibrous fracture, has a slight odor, and a bitter, astringent taste.

Constituents.—The tannin of horse-chestnut bark colors iron salts green. Besides some fat, chlorophyll, and other common compounds, the bark contains *æsculin*, $C_{15}H_{16}O_9$, and *fraxin* (*pavin*), $C_{32}H_{36}O_{20}$, both principles being inodorous, of a slightly bitter taste, and showing a blue fluorescence when dissolved in water, particularly in the presence of alkalis. *Æsculin* is obtained by precipitating the decoction with solution of alum and excess of ammonia, evaporating the filtrate to dryness, exhausting the residue with boiling strong alcohol, and recrystallizing. It forms small white needles containing $2H_2O$, which are insoluble in ether and have an acid reaction upon litmus. On boiling with dilute acids it is split into glucose and *æseuletin*. Baryta solution produces the same decomposition, and then yields *glucinic*, *apogluclenic*, and *æseuletinic acids*. *Æseuletin*, $C_9H_6O_4 \cdot H_2O$, crystallizes in colorless needles, is with difficulty soluble in cold water and alcohol, the solutions coloring ferric salts dark-green, dissolves in alkalis with a golden-yellow color, and on boiling with potassa is decomposed into oxalic, formic, and protocatechuic acids. *Fraxin* is obtained by precipitating the alcoholic tincture with an alcoholic solution of acetate of lead, diffusing the precipitate in water, decomposing by sulphuretted hydrogen, evaporating over sulphuric acid to dryness, and removing the tannin by washing with ice-cold water; it dissolves in alkalis with a yellow color, colors ferric chloride green, and then produces a lemon-yellow precipitate.

The integuments of the seeds contain some *æseulin* and *quercitrin*, which are likewise present in the flowers, but the leaves contain yellow *quercitrin*. The cotyledons contain, besides starch and gummy matter, some fixed oil, *oleum hippocastani*, which was obtained by Genevoix (1859) to the amount of $\frac{1}{10}$ per cent. by extracting with ether; it is of a greenish-brown or yellow color, has a turnip-like odor, a somewhat bitter taste, and the specific gravity .927, and congeals near the freezing-point of water. *Argyrescin* and *aphrodæscin* are two amorphous acrid bodies discovered by Rochleder (1862), which are insoluble in ether, soluble in alcohol, and yield with water solutions foaming like a soap solution; the latter is precipitated by baryta-water, and boiled with alkalis yields butyric and amorphous *æscinic acids*; the former is a glucoside.

ÆSCULUS PAVIA, *Linneé*.—Red buckeye.—B. C. Batchelor (1873) obtained from the testa tannin, 3 per cent. of resin, a tasteless crystalline principle, and coloring matter. The cotyledons were found to contain 5 per cent. of greenish-brown fixed oil, $2\frac{1}{2}$ per cent. cane-sugar and syrup, and a brownish, bitter, and acrid glucoside different from *argyrescin*, and apparently poisonous.

Medical Uses.—It is asserted that the bark of the branches, and also the *æsculin* obtained from it, have cured *periodical fevers* in which even quinine failed. The same statement is made respecting numberless bitter vegetable products. It is also stated that *æsculin* will cure *neuralgia*. Oil of horse-chestnut has been used as an embrocation for joints affected with chronic *gout* or *rheumatism*, with the same effect, probably, as any other bland oil, and a decoction of the leaves has had some reputation as a remedy for *whooping cough*. These medicines are of little value—as little, probably, as the entire horse-chestnut, to which, if constantly worn in the pocket, a vulgar superstition ascribes the power of curing hæmorrhoids. This is evidently a survival of the doctrine of signatures. A decoction may be prepared with 1 or 2 ounces of the bark in a pint of water (Gm. 32–64 in Gm. 500), boiled for 10 minutes. *Dose*, a wine-glassful. *Æsculin* may be given in doses of 5 or more grains (Gm. 0.30).

HIRUDO, *Br.*—LEECH.

Hirudines, P. G.—*Sangsue*, Fr.; *Blutegel*, G.

Sanguisuga medicinalis, *Savigny*, and *Sang. officinalis*, *Savigny*.

Class Vermes; Ord. Annulata; Sub-ord. Apoda; Family Hirudineæ.

Description.—Leeches are invertebrate animals with an elongated, roundish, or somewhat flattened body, which has numerous transverse wrinkles, and is generally attenuate toward both ends; the posterior one always terminates by a broad and muscular disk, by means of which the animal fastens itself upon objects. The blood-sucking leeches have their anterior end or head likewise terminated by a narrower disk, in the centre of which is placed the mouth containing three jaws, which are provided with two rows of numerous-pointed teeth, and are mutually inclined at an acute angle, so as to make a triangular incision through the skin. Respiration is carried on through small apertures or *stigmata* arranged in two rows on the abdominal surface and found at every fifth ring. Leeches are hermaphrodites, but mutually impregnate each other. Several pairs of testicles are located in the fore and middle part of the body; the filiform penis is projected from an abdominal orifice about one-third distant from the head, and the female organs with two ovaries have their aperture or vagina five rings below the penis. The ova are deposited near the edge of the water, invested with a kind of a jelly or mucus, which contracts into a capsular or cocoon-like body having a spongy appearance and containing about ten or more eggs. Leeches are aquatic animals, and swim with a vertical undulating motion. For medicinal use their weight should be between 1 and 5 Gm. (15 and 75 grains).

SANG. MEDICINALIS, *Savigny* (*HIRUDO MEDICINALIS*, *Linneé*), has the back of an olive-green color and marked with six longitudinal pale rust-colored stripes, which are mostly spotted with black. The belly is greenish-yellow, more or less spotted with black, occasionally to such an extent that the prevailing color is black. The animal is indigenous to Central and Northern Europe, and is known in commerce as the *Swedish* or *German leech*.

SANG. OFFICINALIS, *Savigny* (*HIRUDO PROVINCIALIS*, *Carena*). The back is green or blackish, marked with six longitudinal rusty-red stripes dotted with black. The belly is light olive-green, unspotted, but marked with a black stripe on each side. This leech is indigenous to the southern part of Europe, and is known in commerce as the *Hungarian leech*. There are several varieties of this species, differing from each other by modifications of the dorsal stripes.

Several other species of *Sanguisuga* are found in Southern Europe and occasionally employed, but are not an article of commerce. Leeches are generally kept in ponds by the wholesale dealer, and even cultivated in this manner. They are usually transported imbedded in moist turf.

The *American leech*, *Hirudo decora*, *Say*, which draws less blood, is sometimes employed. Its back is of a dark-green color and marked with one row of orange-brown and two lateral rows of black spots; the belly is of a light orange-brown color spotted with black.

Preservation.—Leeches require some attention to keep them healthy and in good condition. They are kept in clean river-water in a glass jar covered with a linen cloth and put in a shady place which is free from ammoniacal and other noxious vapors. The temperature is best kept between about 10° and 20° C. (50° and 68° F.), sudden changes being carefully prevented. As soon as the water begins to get turbid or colored the leeches should be placed in clean water of the same temperature and the jar well cleaned from the slimy deposit, which is caused by the transparent epidermis being thrown off every four or five days. To facilitate this removal some material is often put into the jar through which the leech may draw itself, and which, by retaining this slime, will tend to keep the water clean; charcoal, pebbles, clay free from lime, moss, and Irish moss have been recommended and found advantageous for the purpose, and apparatuses have been constructed in which leeches may be kept on a bed of material which permits of a frequent renewal of the water without handling the leeches. If they are kept in moist earth, turf, or clay, this should be examined from time to time and dead animals removed. The water should be changed at least once a week, and oftener in warm weather. It will be observed that the conditions for the preservation of leeches are pure air, pure water, and a pretty uniform temperature. Leeches are subject to several diseases which may become epidemic, and which are recognized by an excessive separation of mucus, ulcerations, tumors, or a flaccid appearance of the body; those thus attacked should be

at once removed from the healthy ones, and placed in a separate vessel in clean water upon a layer of charcoal.

Medical History.—Leeches have been used from time immemorial in Asia, but particularly in Bengal, where they are considered the best means of local depletion. They are especially preferred for rayahs, for women and timid persons, and for the very young and very old (Wise). In Greek medicine they were not apparently known until a late date, the first mention of them being made by Themison, who lived in the century preceding the Christian era. They are scarcely alluded to by Pliny, who flourished a century later in Rome, but subsequently their uses were described by all the Latin and Arabian medical writers, as well as the mode of applying and preserving them and the accidents that may occur from their getting into the throat or stomach.

Medical Action and Uses.—Depletion by leeches is by no means identical with taking blood by venesection, even in its action upon the general system, for the rapidity of the loss in the one case and its slowness in the other produce quite different effects; in the former the impression is direct and sudden, in the other indirect and gradual. In their local action the difference is still more evident, for while in the one case the whole of the blood is despoiled to make a limited and local impression, in the other the object is attained by a very small loss of blood. It must be remembered that the circulatory apparatus is not a mere hydraulic machine, but that the blood-vessels, and especially the capillaries, are endowed with vital contractility which may be modified within a limited area and excited by a local irritation. All active congestions and inflammations are, in their origin, local diseases, and are therefore more or less amenable to local treatment, of which one of the most powerful forms is the abstraction of blood, the essential pabulum of inflammatory processes. Hence the utility of leeches in inflammations in whose immediate neighborhood these animals can be applied; it is not so intelligible when they operate upon the surface of the body immediately over inflamed organs which have no direct communication with the skin, as in pneumonia, metritis, gastritis, enteritis, meningitis, etc. The mere loss of so small a quantity of blood as they abstract from the general circulation does not appear to be a satisfactory explanation. The superiority of leeches over cups as a means of local depletion consists not only in the advantages referred to above, but also in their being applicable to various parts to which cups could not be applied, as the eye, the mouth, the anus, vagina, etc.

Large leeches should be used only when blood is to be freely abstracted and when the part is not very sensitive or exposed. The wounds they make are apt to become ecchymosed and leave visible scars. Small leeches are always preferable for application to the face and neck, for the reasons just given, and also because the bleeding from their wounds is more easily controlled. The number to be used will depend upon the size of the leeches, the quantity of blood to be abstracted, and the vascularity of the part. The part to which the leeches are to be applied should be thoroughly washed with warm water, and even with hot water, if it is not sufficiently vascular. Sometimes a hot-water fomentation is applied to stimulate the skin. In order to induce the animals to bite it is customary to moisten the part with sugared water or milk or to rub it with a piece of raw meat, or the leecher pricks the part with a fine needle and smears the blood over the skin, or he draws from his own finger a drop of blood for this purpose. A common method of applying leeches to a free surface is to put them in a small tumbler or wine-glass and invert it over the part. Others place the creatures in a cup and direct them, as they crawl over its edge, to the part where they should bite. For application to the nostril, throat, or vagina the leech may be enclosed in a tube open at both ends.

A healthy leech of medium size will draw from 1 to 2 fluidrachms of blood, and as much more will usually flow after the animal has fallen. When a strong and rapid impression is to be made by leeches the number applied at once should be considerable, but when a slow though continuous action is desired a succession of them may be used. This is often the case in traumatic and other inflammations within the cranium. It is an ancient custom, instead of applying many leeches, to apply one or two or a comparatively small number, and when they are nearly gorged to puncture their bodies near the tail with a needle or fine lancet, when they will often continue to draw blood indefinitely. In any case the punctures will not soon cease bleeding if they are kept sponged with warm water. Sometimes there is a difficulty in stopping the flow of blood, particularly if the wound is in the epigastrium, on the neck, or on some other part where firm pressure cannot readily be made. The various hæmostatics may here be applied, several of them being of common use in domestic medicine, such as scraped lint, burned rag, agaric, cobweb, powdered rosin, India-rubber softened by heat, vinegar and water, etc. If these fail

or in their stead, a saturated solution of alum in hot water may be applied on lint while the liquid is hot, or lint saturated with a solution of perchloride of iron or of tannic acid, or the lunar-caustic pencil reduced to a fine point, may be inserted in the wound, or, finally, the point of a red-hot knitting-needle may be used in the same way. In all these cases the action of the hæmostatic should be aided by pressure with the hand, or with a small clamp or pincers made for the purpose, or by passing a needle through the skin, including the wound, and surrounding it with a ligature in the form of a figure-of-eight.

Small leeches are sometimes taken in drinking-water, and attach themselves to the fauces or pharynx, and have even penetrated into the larynx and fatally obstructed it. A strong gargle of salt and water usually suffices to make them quit their hold, and vinegar will have the same effect. These liquids have been used, and also wine, when leeches have been swallowed, but the creatures would probably be unable to live under the action of the gastric juice. In some cases, and especially when the leech has entered the larynx, its presence has been discovered by the laryngeal mirror; and in one case, at least, laryngotomy was performed for its removal.

When leeches have been gorged with blood they are not, if left to themselves, fit to be used again for several months. But by placing them in a weak solution of salt and water or of vinegar and water they may be made to disgorge the blood they have swallowed, and they soon regain their vigor if they are then placed in fresh water. They may also be emptied of their blood by stripping them. Such leeches are more subject to disease, and they should be kept separate from the fresh ones.

HORDEUM DECORTICATUM, Br.—PEARL BARLEY.

Hordeum, U. S. 1870; *Hordeum perlatum*.—*Orge perlé*, Fr.; *Perlgerste*, *Perlgraupe*, G.

The husked seeds of *Hordeum distichon*, *Linné*. Bentley and Trimen, *Med. Plants*, 293.

Nat. Ord.—Graminacæ.

Origin.—Barley is probably indigenous to Western Asia, and has been cultivated from a very early period. It is now raised in most parts of the temperate zones, and in Europe within the Arctic Circle. Besides the two-rowed or long-eared barley, *Hord. vulgare*, *Linné*, the four-rowed or spring barley and *H. hexastichon*, *Linné*, or six-rowed barley, are the principal species cultivated. The fruit of these species is used indiscriminately in the preparation of malt, and, when deprived in suitable mills of the integuments and rounded at the ends, constitutes the official pearl barley.

Description.—Pearl barley is nearly globular, of a white color and mealy appearance, with the exception of a groove in which fragments of the integuments are present.

FIG. 149.

Barley starch-granules.

The larger pearls still contain externally a layer of gluten; the smaller ones consist altogether of the mealy albumen, and are formed of a cellular tissue filled with starch-granules, which resemble wheat starch and are made up of small and large grains with few intermediate ones. They are irregularly circular or elliptical in shape, with the nucleus or hilum rarely perceptible and the layers indistinct. Pearl barley is inodorous and has an insipid taste.

Constituents.—The average of the various analyses made by different chemists gives to barley 60 to 68 per cent. *starch*, 12 to 16 per cent. of *protein compounds* consisting of gluten and albumen, 2 to 3 per cent. of *oil*, the same of *ash*, 10 to 14 per cent. of *moisture*, and 8 to 12 per cent. of *cellulose*. Lerner (1863) found in exsiccated barley also 6.6 per cent. of *dextrin* and traces of tannin and bitter principle, and Lintner (1868) a little cholesterin. Proust's *hordein* was proven by Braconnot and Guibourt to be a mixture of cellular tissue, starch, and gluten. Beckmann's (1855) *hordeic acid* is evidently a fatty acid liberated by the oil of vitriol used in its preparation.

Pharmaceutical Preparations.—*FARINA HORDEI PRÆPARATA*, *P. G.* 1872.—Prepared barley flour, *E.*—Barley flour is pressed into a well-tinned or stoneware cylinder, so as to fill only two-thirds of the vessel, which is well closed and heated in a steam-bath for 30 hours. The upper layer of the flour is then removed, and the remaining portion pulverized and preserved in a dry and cool place. It is a yellowish or pale-reddish powder having a sweetish and mucilaginous taste, and contains dextrin and other derivatives of starch and of gluten.

Off. Prep.—Decoctum hordei, *Br.*

Medical Uses.—From the earliest times barley has been used not only as food, but to prepare drinks for the sick, especially in febrile diseases and in pulmonary and urinary disorders. It is now seldom employed externally, but continues to be given internally and for the same purposes as of old. The addition of honey makes barley-water more efficient in *bronchial affections* and *sore throat*. Formulæ for preparing it are given under **DECOCTUM HORDEI**.

HUMULUS, *U. S.*—Hops.

Lupulus, Br.; *Strobili humuli*, s. *lupuli*.—Hop, E.; *Houblon*, Fr.; *Hopfen*, G.

The strobiles of *Humulus Lupulus*, Linné. Steph. and Church, *Med. Bot.*, plate 41; Bentley and Trimen, *Med. Plants*, 230.

Nat. Ord.—Urticaceæ, Cannabineæ.

Origin.—The hop is distributed over a great portion of the northern temperate zone, and has been introduced into Brazil and Australia. It grows in hedges and thickets, and is indigenous to North America, where it is particularly common in the northern and western regions, and is found in the Sierra Madre range of Colorado at an altitude of 10,000 feet; it is met with also in Middle and Southern Siberia and throughout the greater portion of Europe. In many countries it is extensively cultivated. It is a perennial, producing rough, long, and twining stems, which have the leaves mostly opposite, heart-shaped, and three- to five-lobed. The staminate flowers are in short racemes, and the pistillate flowers in densely-leafy, cone-like spikes upon different plants; the spikes or strobiles are the parts used.

Description.—The strobiles are ovate in shape, 1 to 1½ inches (25–38 Mm.) long, and consist of a grayish, hairy, zigzag-shaped, somewhat glandular axis, to the angles of which the enlarged leafy bracts and scales are attached; these are obliquely ovate, membranous, parallel-veined below, reticulately veined above, and at the base glandular and surrounding a subglobular akene, which is likewise covered with numerous yellow and shining glands (*lupulin*). Hops are of a yellowish-green color, of an agreeable aromatic odor, and of a bitter, aromatic, slightly astringent taste. When kept for some time hops acquire a brownish color, and an unpleasant odor from the formation of some valerianic acid; these changes are prevented, or at least retarded, by exposure to sulphurous acid gas, and the color of brown hops is to some extent restored by the same means.

(For an account of the culture of hops in the United States consult papers by W. H. Ramsey in *Amer. Jour. Phar.*, 1875, p. 241, and E. G. Bissell, 1877, p. 538.) In the fiscal year 1876–77, 20,177 pounds of hops were imported into the United States, and 874,559 pounds in 1882.

Constituents.—Besides the principles contained in the yellow glands (see *LUPULINUM*), hops contain about 4 per cent. of *tannin*, which, according to R. Wagner, resembles moritannic acid. Bissell (1877), however, found its behavior to mineral acids entirely distinct, and noticed that only a small portion of it is precipitated by gelatin. Bowman (1869) obtained by means of this reagent 3.67 per cent. of tannin. Hops, entirely freed from lupulin, gave to Bissell, with water, a neutral distillate having an odor distinct from that of hops, and containing mere traces of organic matter; the extract was but slightly bitter. Hops contain 0.8 per cent. of volatile oil (R. Wagner, 1853), between 9 and 18 per cent. of resin (Siewert, 1870), some trimethylamine, and a volatile alkaloid, *lupuline* (Griessmayer, 1874); this alkaloid is liquid, has a strong coniine-like odor and an alkaline not bitter taste, and gives with phosphomolybdic acid a white or yellow precipitate which dissolves with a blue color in an excess of ammonia. Sacc (1876) asserted that hops contain a peculiar fermentative principle, which was disproven by Soxhlet and Pasteur (1876). C. G. Wheeler (1865) found hops to contain 1.7 per cent. of nitrogen, and to yield 7 to 10 per cent. of ash, in which potassa, lime, phosphoric acid, and silica predominate.

Off. Prep.—*Extractum lupuli*, *Infusum lupuli*, Br.; *Tinctura humuli* (*lupuli*), *U. S.*, Br.

Physiological Action.—Experiments on animals do not indicate the existence of a narcotic principle in hops, but clearly a sedative one, since under the use of hops the pulse-rate is diminished. Like other bitters, hops tend to invigorate digestion. Lupulin in moderate doses has the same effect, and in large ones causes abdominal pain and constipation. It certainly calms disordered nervous action, and in this manner favors sleep, but there is no evidence to show that hops, when given to persons in health or free from pain, have distinctly shown narcotic properties. The apparently direct influence of the

hop-pillow in causing sleep is one which it shares with all odorous flowers, and is due to the essential oil which the strobiles contain.

Medical Uses.—The association in hops of a bitter tonic with a direct sedative of abnormal nervous action renders them peculiarly fitted to relieve those numerous cases of *dyspepsia* which are due to abuse of the stomach when it is both irritated and exhausted. Hence at one time they were celebrated in the treatment of atonic *gout*, a disease in which those conditions are prominent. These qualities also explain their reputation in the treatment of the forms of constitutional derangement which exist in *scrofula* and *rickets* when anaemia, glandular swellings, cutaneous eruptions, and dropsy, especially of the abdomen, are present. Hop-tea is one of the best remedies for *delirium tremens*, tending to restore its tone to the irritated and exhausted stomach, and directly to allay the characteristic nervous excitement of the attack. In various affections attended with genito-urinary irritation, as *priapism*, *seminal emissions*, *nocturnal incontinence of urine*, and *irritable bladder*, hops are often most salutary. As an external application to relieve the pain of *muscular rheumatism*, *abscesses*, *spasms*, *toothache*, *colic*, *bruises*, etc. hops form a most excellent application. They may be incorporated in a poultice, or the strobiles, enclosed in a bag, may be moistened with hot water, vinegar, or alcohol, and applied to the painful part. In this way hops are often associated with chamomile, thyme, lavender, mint, etc. The infusion of hops is the best preparation for internal use, although so much more bulky than the tincture or the fluid extract of lupulin. Its *dose* is from 1 to 2 fluidounces (Gm. 32–64). A pure and strongly hopped beer contains all the virtues of this agent, but ordinary malt liquors are too often fraudulently adulterated to deserve such praise.

HURA.—SAND BOXTREE.

Sablier, Fr.; *Sandbüchsenbaum*, G.

Nat. Ord.—Euphorbiaceæ.

Description.—The following species have attracted some attention:

HURA CREPITANS, *Linné*, indigenous to the West Indies and Central and some portions of South America, and known there as *ajuarar*. It is a straight tree, about 70 feet (21 M.) high, with long petiolate, cordate-ovate, and serrate smooth leaves, pendulous ovate staminate catkins, erect dark-red or purple pistillate flowers, and depressed globular twelve- to eighteen-celled capsules, which when ripe break with some violence, scattering the roundish flattened seeds, which have an agreeable sweetish taste. The tree contains a very acrid milk-juice. The leaves, steeped in oil, are used in rheumatic complaints.

HURA BRASILIENSIS, *Willdenow*, known in Brazil as *assaou* or *ussau*, resembles the preceding in appearance and properties, but has oblong catkins. The thick, hard, grayish, inodorous, and slightly acrid bark, *casca de assaou*, is employed in South America.

Constituents.—Boussingault and Rivero (1825) ascertained that one of the acrid principles of the milk-juice is oily and volatile—the other, *kurin*, is crystallizable; the other constituents found were malates, nitrates, etc. Bonastre found in the integuments of the seeds much coloring matter, tannin, and gallic acid, and in the kernel 51 per cent. of fixed oil soluble in alcohol, solid fat, albumen, and salts. The oil is purgative.

Allied Plant.—**HIPPMANE MANCINELLA**, *Linné*.—Manchineel. *E.*—A large West Indian tree, with ovate, acute, finely serrate leaves, which are about 2 inches (5 Cm.) long. The fruit resembles a small apple in size and color, is internally white and soft-fleshy, and contains from three to seven woody cells, each with a roundish-triangular silvery seed. All parts contain an acrid poisonous milk-juice; the poisonous principle appears to be volatile. Ricord-Madianna (1827) found, in addition to this *mancinellin*, volatile oil, fat, resin, caoutchouc, and gummy matter.

Medical Action and Uses.—Like several other Euphorbiaceæ, it is a powerful irritant, and taken internally in large doses occasions violent vomiting and purging. For these reasons, probably, it is used as an *anthelmintic*. Applied to the skin in decoction, it causes irritation and even vesication. In its native country, Brazil, it is much used in the treatment of *leprosy*, but there is no evidence of its having cured the disease. It is given in the form of a decoction, made by boiling half an ounce of the bark in a pint of water to half a pint (Gm. 16 in Gm. 250). Baths made with a saturated infusion of the bark are also employed. It is almost unnecessary to add that neither this medicine nor any other ever cured leprosy, and that the use of a drastic medicine like *hura* cannot fail to hasten the inevitable progress of the disease.

HYDRANGÆA.—HYDRANGÆA.

The root of *Hydrangea arborescens*, *Linné*.

Nat. Ord.—Saxifragacæ, Hydrangææ.

Origin and Description.—The wild hydrangea grows near the banks of rivers, preferring rocky places, from Pennsylvania westward to Illinois and southward. It has a pale-brown, internally whitish, woody, and much-branching root, which is of a sweetish and pungent taste. The stem is about 6 feet (1.8 M.) high, and has a grayish, or on the branches a light reddish-brown, bark, which is detached in thin concentric layers, from which circumstance the shrub is known as *seven barks*. The leaves are opposite, nearly smooth, ovate, pointed, rounded or slightly heart-shaped at the base and serrate on the margin. The flowers, which appear in July, are in flat cymes, whitish, the marginal ones often sterile and radiant, with four or five petals, and stamens twice that number. The fruit is a two-celled and two-beaked capsule, containing numerous seeds.

Constituents.—Nothing is known about the principles to which the medicinal properties of the root might be due. Laidley's analysis (1850) merely proved the presence of the common vegetable principles—gum, starch, resin, etc.

Medical Uses.—We are told that hydrangea-root was employed by the Cherokee Indians for the relief of calculous complaints, and that when duly administered to persons suffering from *urinary concretions* in the kidneys and bladder it provokes their discharge. We are also informed that in over-doses it occasions vertigo, oppression of the chest, etc. (*U. S. Dispensatory*, 12th ed.). If these qualities really belong to the medicine, it presents the singular case of being at once diuretic and narcotic. However this may be, there seems to be good reason to believe that hydrangea has been found useful in *gravel* and its associate disorders. In 1880 it was reported that the fluid extract had "a solvent effect on lithate of ammonia," and in the following year, that it put an end to attacks of renal colic which had beset a patient for years (Edson). A little later several aggravated cases of this affection were reported by N. F. Brown, in which the medicine seemed to be perfectly successful (*Med. Record*, xvii. 471; xx. 652; xxi. 39). The best form in which it can be administered is a fluid extract, which may be given in teaspoonful doses.

HYDRARGYRI CHLORIDUM CORROSIVUM, U. S.—CORROSIVE CHLORIDE OF MERCURY.

Hydrargyri perchloridum, Br.; *Hydrargyrum bichloratum*, P. G.; *Hydrargyrum muraticum corrosivum*, *Hydrargyrum corrosivum sublimatum*, *Hydrargyri bichloridum*, *Sublimatus corrosivus*, *Sublimatum corrosivum*, *Mercurius sublimatus corrosivus*, *Chloruretum* (*Chlorretum*) *hydrargyricum*.—*Mercuric chloride*, *Perchloride of mercury*, *Corrosive sublimate*, *Bichloride of mercury*, E.; *Deutochlorure de mercure*, *Sublimé corrosif*, *Chlorure mercurique*, Fr.; *Ätzendes Quecksilberchlorid*, *Ätzender Quecksilbersublimat*, G.

Formula HgCl_2 . Molecular weight 270.5.

Preparation.—Take of Sulphate of Mercury 20 ounces; Chloride of Sodium, dried, 16 ounces; Black Oxide of Manganese, in fine powder, 1 ounce. Reduce the sulphate of mercury and the chloride of sodium each to fine powder, and, having mixed them and the oxide of manganese thoroughly by trituration in a mortar, put the mixture into an apparatus adapted for sublimation, and apply sufficient heat to cause vapors of perchloride of mercury to rise into the less heated part of the apparatus, which has been arranged for their condensation.—*Br.*

Mercuric chloride is formed by the mutual decomposition of mercuric sulphate and sodium chloride; $\text{HgSO}_4 + 2\text{NaCl}$ yields $\text{HgCl}_2 + \text{Na}_2\text{SO}_4$. By heat, mercuric sulphate is partly decomposed (see HYDRARGYRI SULPHAS), and the product of the above process is thereby apt to become contaminated with mercurous chloride or calomel; to prevent such a result, the British Pharmacopœia directs the addition of a little binoxide of manganese, which, reacting with some of the sodium salt, generates chlorine sufficient to reconvert any mercurous into mercuric salt. On conducting the vapors into a large chamber they are condensed in the form of a heavy white crystalline powder.

Properties.—Corrosive sublimate forms colorless rhombic prismatic crystals, or, more generally, heavy white crystalline masses. It has the density 5.4, and when heated to about 265° C. (509° F.) fuses, and at a higher temperature sublimes without leaving any residue. It is permanent in the air, is inodorous, has a disagreeable acrid metallic taste, and dissolves in about 2 parts of boiling water and 16 parts of water at 15° C.

(59° F.) (Poggiale); also in 3 parts (2.3 parts, Simon) of alcohol, in 4 parts of ether, freely in volatile oils, and in 1.2 parts of boiling alcohol. In the presence of camphor the solubility is increased, so that 4 parts of ether and 16 parts of camphor will dissolve 8 parts of corrosive sublimate, and 4 parts of alcohol, with 25 parts of camphor, will dissolve 16.5 parts of corrosive sublimate (Karls, 1827; Simon, 1836). The aqueous solution has an acid reaction, becomes neutral on the addition of sodium chloride, and when exposed to the light is partly decomposed, with the precipitation of calomel and the liberation of hydrochloric acid; the decomposition is prevented by the presence of free hydrochloric acid or of ammonium chloride. The aqueous solution yields yellow precipitates of mercuric oxide with an excess of lime-water (see LOTIO HYDRARGYRI FLAVA) or potassa solution, a white precipitate of ammoniated mercury with ammonia, and on the addition of nitrate of silver a white curdy one of silver chloride, insoluble in nitric acid, but soluble in ammonia. Phosphorous and sulphurous acids separate calomel from the solutions; hypophosphorous acid and stannous chloride produce the same change, but when in excess and heated liberate metallic mercury. The salt is soluble without decomposition in sulphuric, hydrochloric, or nitric acid, and crystallizes again on cooling. Solutions of albumen or of tannin, forming insoluble compounds, are used as antidotes to corrosive sublimate.

FIG. 150.

Crystal of Corrosive Sublimate.

ride produce the same change, but when in excess and heated liberate metallic mercury. The salt is soluble without decomposition in sulphuric, hydrochloric, or nitric acid, and crystallizes again on cooling. Solutions of albumen or of tannin, forming insoluble compounds, are used as antidotes to corrosive sublimate.

Tests.—Corrosive sublimate should volatilize when heated without leaving any residue (absence of fixed impurities), and should be completely soluble in water or alcohol (absence of calomel). It often contains traces of arsenic, which are probably derived from the sulphuric acid with which the sulphate was prepared; this may be readily detected by mixing the solution with an excess of potassa solution, adding some zinc, and heating, the test-tube being covered with filtering-paper moistened with a drop of solution of silver nitrate; the appearance of a black spot indicates arsenic; or, “if 1 Gm. of the salt be dissolved in boiling water, then mixed with 5 Ccm. of strong solution of soda (sp. gr. about 1.260) in a long test-tube, and about 0.5 Gm. of fine aluminium wire, cut into small pieces, be added (a loose plug of cotton being pushed a short distance down the tube), the generated gas should not impart any tint to paper wet with test solution of nitrate of silver and kept over the mouth of the test-tube for half an hour (absence of arsenic).”—*U. S.* “The aqueous solution, when completely precipitated by hydrosulphuric acid, should yield a colorless filtrate, which on evaporation should leave no residue (absence of salts of alkalis, earths, and certain metals); and if the precipitated sulphide of mercury be agitated with diluted ammonia-water, the filtrate on being acidulated and tested with hydrosulphuric acid should not give a yellow precipitate (absence of arsenic).”—*P. G.* J. G. Smith (1877) found in some samples $\frac{1}{16}$ per cent. of arsenious acid.

Pharmaceutical Uses.—Corrosive sublimate is employed in making Hydrarg. oxidum flavum, Hydrargyrum ammoniatum, *U. S., Br.*; Hydrarg. iodidum rubrum. Liquor hydrarg. perchlor., and Lotio hydrarg. flava, *Br.*

Physiological Action.—*On Plants and Animals:* A solution of 1 part of this salt in 1000 of water prevents the germination of seeds and the communicability of the vaccine virus, and destroys the life of plants, leeches, and fish immersed in it. Marcy's experiments led him to conclude that no other agents possess a germicide power equal to that of corrosive sublimate. “To-day,” he remarks, “it clearly ranks first of all the known agents as a disinfectant” (*Jour. Am. Med. Assoc.*, i. 199). Introduced into the connective tissue, it is absorbed, and occasions the same symptoms and lesions of gastrointestinal inflammation as if it had been given by the mouth. These symptoms include gastric pain, thirst, vomiting of mucus and blood, and death by convulsion or exhaustion. The lesions vary from slight redness to complete softening of the mucous membrane of the stomach; similar ones may be found in the intestine, and especially in the rectum.

On Man: Poisoning by corrosive sublimate may be produced by its external application as well as by its being taken internally. A solution of it applied to the unbroken skin has repeatedly caused symptoms of poisoning, such as an acrid taste in the mouth, irritation of the œsophagus, vomiting, epigastric pain, constriction of the chest, and a small and irregular pulse. When the skin is not whole the same and more aggravated effects arise, including those of severe local irritation, and the absorption of mercury is proved by the salivation that ensues, and sometimes by the deposit of mercury upon

articles of gold worn next the skin. Poisonous doses of this salt cause constriction and severe burning pain in the fauces, œsophagus, and stomach, with retching and the vomiting of mucus, bile, and blood; the abdomen grows painful under pressure; there is tenesmus, and sometimes there are bloody stools. Intense thirst, a quick, frequent, and small pulse, labored breathing, a cold and clammy skin, and scanty or suppressed urine, are also observed. Death may occur within a few hours or may be delayed for several weeks. If recovery takes place the stomach and bowels remain irritable for a long time. After death from this poison the stomach is contracted and the mucous membrane of the œsophagus, stomach, and small intestine is occasionally injected and sometimes ulcerated. Excessive doses convert the gastric mucous membrane into a soft pulp. After death from 60 grains of this salt the kidneys are said to have been very large and heavy, not flattened, but almost cylindrical, and gorged with blood (*Boston Med. and Surg. Jour.*, Nov. 1879, p. 781). Smaller but not fatal doses present the above symptoms in a milder form and degree, and sometimes, although rarely, cause salivation. Indeed, of all mercurial compounds, this one is least apt to salivate when taken by the stomach. The presence of a large proportion of table-salt in the food is said to prevent in a great measure the absorption of the bichloride, while a moderate proportion of salt promotes its absorption. The latter may have been the cause of its toxical effects in the case of a man who took two pills which contained $\frac{1}{8}$ grain (Gm. 0.02) with $\frac{2}{3}$ grain (Gm. 0.04) of chloride of sodium. He was attacked with violent vomiting, colic, and purging, his pulse became thready, his extremities cold, and his features sunken. He, however, recovered (Kobryner). It is related that a woman after taking 3 drachm doses of "liquor hydrarg. perchlor." (*Br. P.*), each containing $\frac{1}{16}$ grain of corrosive sublimate, was attacked with persistent vomiting and had a temperature of 104° F. (*Practitioner*, xxix. 18).

Medical Uses.—Corrosive sublimate has never lost the pre-eminence which it shared with calomel of being one of the best internal remedies for *syphilis*. In general, it is found not to salivate unless given in doses of at least $\frac{1}{2}$ grain twice a day, but even in smaller doses it should be guarded by being associated with some syrup, bitter extract, or opium, and taken directly after meals. To prevent its decomposition in solution, it should be given along with muriate of ammonia, in the proportion of 1 grain of the bichloride to 5 grains of the latter salt. To this solution alcohol should be added in the proportion of 1 part to 10. It is preferable to prescribe as many daily doses of the medicine as the patient takes meals, in order to lessen the chances of gastro-intestinal irritation. In appropriate quantities this preparation is undoubtedly the best in infantile syphilis. About $\frac{1}{30}$ grain (Gm. 0.003) should be given in solution three times a day, and generally prescribed in a syrup or mixed with one when administered. If diarrhoea occurs, it should be corrected by diminishing the frequency or the size of the dose and by adding to it a minute proportion of laudanum. Baths of the bichloride have been used to cure syphilis, and with very great success; they are not apt to salivate, but the irritation of the skin they occasion renders them objectionable. The salt has also been employed hypodermically, but if it is more efficacious in this manner than when given internally, the inconvenience of repeating the operation and the severe local effects produced by it have caused the method to be abandoned by the greater number of syphilologists. According to Martineau, the latter objection is obviated by using an ammoniated peptonate of the bichloride of mercury, but his method has not been successful in the hands of others (*Bull. de thérap.*, ci. 91; ciii. 89). It must be added, however, that some, like Letnik, believe that the subcutaneous injection of mercury will supersede all other methods of treating syphilis, because it enables the physician to graduate the dose of the medicine—because, also, it dispenses with baths and frequent changes of linen, does not hinder the patient from pursuing his usual calling, and shortens the duration of the treatment. The salt preferred by him was "chloride of mercury with sodium chloride," but he did not make any experiments with mercury albuminate (*Edinb. Med. Jour.*, xxviii. 370). The peptonated bichloride was claimed by Terillon in 1880, and was still maintained by Martineau in 1882, to possess all the advantages hitherto attributed to it, including a rapid improvement in the general nutrition and the constitution of the blood; but it has been alleged, on the other hand, that its use hypodermically is very painful and irritating, and that its cures are not more radical than those obtained by inunction or by the internal administration of mercury (*Bull. de thérap.*, xcix. 150; *Med. Record*, xx. 684; *Bull. et Mémoires de la Soc. de thérap.*, Oct. 1882, p. 188). In 1881 the albuminate was introduced, and its efficacy was stated to have been equal, if not superior, to that of the peptonate, while it was free from the objections urged against that preparation (Gourgues, *Bull. de*

thérap., cii. 49). It has been claimed that a solution of $\frac{1}{4}$ gr. of the bichloride (Gm. 0.016) in an ounce (Gm. 32) of water is of great efficacy, both topically and internally, in the treatment of *diphtheria*. The dose used internally was $\frac{1}{32}$ gr. every one or two hours. An examination of the reports upon this subject suggests that the treatment, even if inoperative by itself, would be safer than the perturbative method for which it was in most instances substituted.

FORMAMIDATE OF MERCURY has been recommended for treating *syphilis* hypodermically by Liebreich (1882). In solution it causes neither local irritation nor salivation, according to this authority; but others have not found it so innocuous, and, indeed, object to it on account of the inflammation it excites. It has been used in a solution of 1:100, of which the amount injected daily varied from Gm. 0.5–1, equal to Gm. 0.005–0.010, or gr. $\frac{1}{12}$ to $\frac{1}{4}$, of the salt.

In various diseases of the *skin* solutions of corrosive sublimate are useful topical applications, but the strength of the preparation should be carefully regulated, and none should be employed if the skin is broken. *Psoriasis*, when inveterate, has been successfully treated by baths containing corrosive sublimate, the patients taking from 30 to 40 baths, kept at a lukewarm temperature, and remaining immersed from a half to three-quarters of an hour (Voss and Spenk, *Med. News and Abs.*, June, 1881, p. 356). A solution of 15 grains (Gm. 1) of the salt in a pint of water, or, still better, in 2 fluid-ounces of dilute alcohol and 14 fluid-ounces of water, forms a very efficacious lotion in many cases of *acne*, especially in the form which affects the noses of certain women at their menstrual periods; in *chloasma*; in lentigo and the discolorations of the skin which go under the general name of *freckles*; in *prurigo pudendi* as a palliative, and in *pytiasis* usually as a cure. A solution of 2 grains in an ounce of water is one of the best agents for destroying *pediculi pubis*, and is most efficiently applied with a fine-tooth comb. *Malignant pustule* is said to be treated more efficiently than by any other method with corrosive sublimate applied to the raw surface of a crucial incision made through the hardened tissues. *Ozena*, especially of syphilitic origin, is benefited by the injection into the nostrils of weak solutions of the bichloride containing 1 or 2 grains (Gm. 0.06–0.12) to the ounce (Gm. 32) of water, or by a weaker solution applied with the nasal douche. In chronic vaginal *leucorrhœa* a similar application is sometimes useful. The nasal injection is objectionable, owing to the danger of the medicine being swallowed. Syphilitic *condylomata* have been successfully treated by washing them with a solution of common salt, and then sprinkling calomel powder over them. This method is said to be less painful than the direct application of corrosive sublimate (Nussbaum).

The inhalation of an atomized solution of Gm. 0.01 of the bichloride of mercury in Gm. 100 of distilled water (gr. $\frac{1}{4}$ in f3ij) is stated to have cured *fœtid bronchitis* (*Centralbl. f. d. ges. Ther.*, ii. 61).

In the subacute and chronic forms of muscular and also of articular *rheumatism* a very gentle but sustained mercurial action will sometimes put an end to the lingering stiffness of the joints. For this purpose minute doses of the bichloride in compound syrup of sarsaparilla will be found appropriate. In chronic rheumatic *arthritis* it is said that baths of the bichloride and compresses wet with solutions of the salt have sometimes produced cures of this intractable disease. It is recommended that a full bath should contain from 3 to 8 drachms (Gm. 12–32) of the salt. The many possible dangers from so large a quantity of a poisonous liquid should condemn its use for a disease in which its utility is so questionable.

HYDRARGYRI CHLORIDUM MITE, U. S.—MILD CHLORIDE OF MERCURY.

Hydrargyri subchloridum, Br.; *Hydrargyrum chloratum*, P. G.; *Hydrargyri chloridum*, *Hydrargyrum chloratum (muriaticum) dulce*, *Mercurius dulcis*, *Calomelas*, *Chloruretum* (*Chloretum*) *hydrargyrosus*.—*Calomel*, E., Fr., G.; *Mercurous chloride*, *Subchloride* (*Protochloride*) of *mercury*, E.; *Protochlorure* (*Sous-muriate*) de *mercure*, *Mercure doux*, Fr.; *Quecksilberchlorür*, G.

Formula Hg_2Cl_2 (or HgCl). Molecular weight 470.2 (or 235.1).

Preparation.—Take of Sulphate of Mercury 10 ounces; Mercury 7 ounces; Chloride of Sodium, dried, 5 ounces; Boiling Distilled Water a sufficiency. Moisten the sulphate of mercury with some of the water, and rub it and the mercury together until globules are no longer visible; add the chloride of sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size

that the calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling distilled water until the washings cease to be darkened by a drop of sulphide of ammonium. Finally, dry at a heat not exceeding 212° F., and preserve in a jar or bottle impervious to light.—*Br.*

Mercuric sulphate is first mixed with the requisite quantity of mercury to form mercurous sulphate, Hg_2SO_4 , and afterward with chloride of sodium. On heating the mixture reaction takes place between the two salts, resulting in the production of mercurous chloride, which sublimes, and sodium sulphate, which remains behind; $\text{Hg}_2\text{SO}_4 + 2\text{NaCl}$ yields $\text{Hg}_2\text{Cl}_2 + \text{Na}_2\text{SO}_4$. If these vapors are cooled and condensed in a small space, white or yellowish-white crystalline masses are obtained, which should be finely powdered. To avoid this operation, the condensation is directed to be effected in a large chamber, whereby a fine crystalline powder is obtained; it is condensed in a similar form, but still finer and as a still softer powder, by injecting steam into the condensing-chamber while the sublimation is in progress. Calomel prepared in this way is designated in the German Pharmacopœia as *Hydrargyrum chloratum vapore paratum*, and is known in France as *Calomel à la vapeur*. Water being at the same time condensed, it will hold any corrosive sublimate in solution which may have sublimed with the vapors of calomel. It is for the purpose of removing the same impurity that the ordinarily-condensed calomel requires to be washed with water as long as mercuric chloride is dissolved, which is indicated by the filtrate producing a white turbidity with ammonia or a black one with sulphhydrate of ammonium. A current of cold air injected into the condensing-chamber will precipitate the calomel vapors as a soft powder in a manner similar to that produced by steam.

Very finely-divided calomel, *Hydrargyri chloridum mite præcipitatione paratum*, known in France as *Précipité blanc* (which should not be confounded with ammoniated mercury), is obtained by gradually adding a not too concentrated solution of mercurous nitrate to a solution containing an excess of sodium chloride, digesting the mixture for a short time, and washing the precipitate thoroughly with water. Wöhler (1854) proposed the reduction of corrosive sublimate in solution by sulphurous acid and by warming the mixture. Good results and nearly the theoretical quantity of calomel are obtained, according to Sartorius (1855), if the corrosive sublimate has been dissolved in 80 parts, or, according to Stein (1857), in 45 parts, of water. Concentrated solutions yield only one-half the mercury as calomel.

Besides calomel manufactured in the United States, 2400 pounds were imported in 1875, and 8177 pounds in 1881.

Properties.—Calomel is a heavy, fine, smooth, and impalpable white powder, which under the microscope is observed to consist of minute needle-shaped crystals, but when prepared by levigating the crystallized mass it forms irregular fragments of crystals. These two varieties are usually met with in commerce. Calomel obtained by precipitation is in very minute particles, either crystalline or amorphous, but on account of its more energetic action is rarely used. The salt is without action on test-paper, is entirely inodorous and tasteless, and is not altered in the dark on exposure to the air; but if kept in the light it gradually acquires a gray or blackish color, indicating decomposition. Its density is about 7.0, but varies somewhat as prepared by different processes. When heated it sublimes completely without previous fusion. It is insoluble in water and other simple solvents, but boiled with water it is slowly decomposed into metallic mercury and mercuric chloride. Solutions of the fixed alkalis and alkaline earths decompose it, with the formation of soluble chlorides and black mercurous oxide Hg_2O (see LOTIO HYDRARGYRI NIGRA): ammonia-water also colors it black, but the resulting compound has the composition $\text{NH}_4\text{Hg}_2\text{Cl}$. When mixed with a dry caustic alkali, alkaline earth, or an alkali carbonate, and heated, decomposition takes place, metallic mercury being produced. Moist calomel is reduced to the metallic state by many metals either in the cold or on being warmed, soluble chlorides and metallic mercury being formed. Boiling nitric or sulphuric acid dissolves calomel, with disengagement of nitric oxide or sulphurous acid vapors and the production of mercuric chloride and nitrate or sulphate. Boiling concentrated hydrochloric acid dissolves mercuric chloride and leaves mercury; in the diluted state, and heated in contact with the air, mercuric chloride is slowly dissolved without separation of mercury. Calomel left in contact with solution of ammonium chloride is gradually converted into mercuric chloride, which dissolves; the decomposition occurs more rapidly with a concentrated solution and at a somewhat elevated temperature. Potassium and sodium chlorides have a similar effect, but react more slowly. According to Jolly's observations (1878), corrosive sublimate is also formed from calomel in the

presence of hydrochloric acid, citric acid, alkalies, their carbonates, and alkaline earths, but not with calcium carbonate or with sugar which is absolutely free from lime. Chlorine-water converts calomel into corrosive sublimate. With potassium iodide a green powder is produced containing mercurous iodide. When triturated with impure sugar some corrosive sublimate is formed.

Tests.—Calomel should volatilize when heated, without leaving any residue (absence of fixed impurities). Heated with potassa solution, it should turn black, without evolving the odor of ammonia (absence of ammonium compounds). Agitated with warm distilled water or alcohol, the filtrate should not be colored by sulphuretted hydrogen, nor yield a white precipitate with silver nitrate (absence of mercuric chloride), nor should it on evaporation leave any residue (absence of fixed soluble impurities). "When moistened with water and placed upon a piece of bright iron, it should not produce a black spot within 1 minute (absence of corrosive sublimate)."—*P. G.* Agitated with diluted acetic acid, the filtrate should not be affected by sulphuretted hydrogen or silver nitrate (absence of ammoniated mercury).

Off. Prep.—*Lotio hydrarg. nigra*, *Br.*; *Pilul. antimonii comp.* (*Hydrarg. subchlor. comp.*), *U. S.*, *Br.*; *Pilul. cathartice comp.*, *U. S.*; *Unguent. hydrarg. subchlor.*, *Br.*

Physiological Action.—The action of calomel does not materially differ from that of uncombined mercury (see *HYDRARGYRUM*); it is, however, rather more irritating, and in excessive doses may cause active vomiting and purging. Among the anomalous effects of calomel is a cutaneous erythema. In the case of an adult male three doses of about 3 grains each occasioned, besides the erythema, malaise, photophobia, hoarseness, fever, thirst, and insomnia (*Boston Med. and Surg. Jour.*, April, 1880, p. 420). It is a remarkable fact that dogs cannot endure, without experiencing hypercatharsis, a third of the doses of calomel which are administered to the youngest children (Bretonneau). No mercurial is so apt to occasion salivation. This and other effects are by no means constantly proportioned to the dose of the medicine; and since it is certain that it must first undergo solution before it can either act locally or be absorbed, the mode in which these results are brought about becomes of interest and has been variously stated and explained. The prevalent hypothesis regarding this point is, that the alkaline chlorides convert the calomel into corrosive sublimate, rendering it soluble and absorbable—an opinion which, considering the poisonous properties of that compound, seems irrational.

The cholagogue action ascribed to mercury, and especially to calomel, was an invention of the British physicians in India, who long accepted the doctrine that large doses of calomel diminish the vascularity of the gastro-duodenal mucous membrane, and dissolve the inspissated mucus investing it and obstructing the gall-ducts, and that small doses of the medicine are absorbed and through the blood promote the secretion of bile. But a careful repetition of their experiments proved that *large doses of calomel, as well as small doses, lessen the biliary secretion*, and that *among purgative medicines mercury in every form is the very one that tends least to augment the discharge of bile*. It seems to be agreed that all purgatives, whether they increase the biliary secretion and excretion or not, tend to hurry forward the bile through the intestinal canal, and thereby prevent its reabsorption after combination with the results of gastric digestion. In this manner mercury becomes a cholagogue, not by stimulating the liver to increased secretion, but by carrying off the bile already secreted, preventing its reabsorption, and thereby diminishing whatever evils may arise from an excessive amount of bile in the liver and in the system generally. It has long been believed that a proof of the cholagogue action of calomel is to be found in the darker color of the stools during its administration, which have hence been called "calomel stools;" and although one or two experimenters have recently reached the same conclusion, yet the more probable opinion is that the color in question is due to the presence of subsulphide of mercury in the dejections, and that even the natural brown color of the feces is produced, not by the bile, which is all reabsorbed in the small intestine, but by a special excretion of the colon. On the whole, the most probable conclusion upon this subject is expressed in these words: "Calomel is not a cholagogue, but diminishes the secretion of bile."

Medical Uses.—When the cure of *sypilis* was believed to depend upon profuse mercurial salivation, calomel was generally employed to produce that effect. But at the present day this action of calomel, along with its tendency to purge, has caused it to be less frequently used than formerly. If prescribed at all, it should be in very small and repeated doses, and the frequency of its administration determined by its effects upon the mouth, the bowels, and the course of the disease. These remarks apply to indurated chancres as well as to secondary symptoms.

Much has been written both for and against the use of calomel in *typhoid fever*, but a careful study of its history seems to show—1, that it is most useful when given in the forming stage of the disease and in purgative doses; and 2, that it is peculiarly mischievous in all cases which tend to assume an ataxic or an adynamic type. In other words, it is to be placed, in relation to typhoid fever, in the same category as other purgatives, among which the salines have been proved to be eminently useful in the first period of the disease. It is very probable that calomel, acting as a purgative, assists in removing the poisonous material from the bowel, and possibly tends to destroy it if it be a ferment, while, owing to its imperfect solubility, the medicine may serve as a protective to the mucous glands of the small intestine. It has been recommended to administer calomel in small and repeated doses, and so as slightly to affect the gums, about the height of the disease, when the tongue grows dry, the abdomen tympanitic, and the mind dull; but if we know anything about the nature of these symptoms, it is that they are signs of increased exhaustion of the nervous system and poisoning of the blood, and therefore the very last to be treated by a medicine which tends directly to aggravate such conditions. The period at which these phenomena appear, only to subside again in three or four days in the natural course of the disease when it tends to recovery, is the one in which the medicine is supposed to be indicated, and the reason assigned for its use probably results, therefore, from an error of observation.

At one time calomel was held to be a specific in *yellow fever*—according to some, if prescribed in large doses; according to others, if given in small doses intended to produce its constitutional effects. Experience has condemned both methods as not only useless, but injurious. The same may be said, but not so absolutely, in regard to *remittent fever*; the necessity of “unloading the portal circulation,” which purgative doses of calomel were supposed to effect, does not now appear so imperative as it did to the theorists of thirty or forty years ago; but the gastro-duodenal inflammation and the engorged state of the liver are undoubtedly allayed by alvine evacuants, among which calomel is one of the best, because it is one of the least irritating, particularly if followed by copious saline draughts in divided portions. The constitutional action of calomel in this disease is no longer sought by judicious physicians.

During the last century, and indeed until within a few years, calomel was used by English and American physicians in all *inflammatory* diseases with complete faith in its efficacy. Borrowed originally from the treatment of acute hepatitis in hot climates, it was applied in England to a totally different order of diseases (plastic inflammations), and gradually came to be regarded as a specific in most of them. Subsequently, this empirical practice was supposed to find a rational justification when it appeared that mercury diminished the coagulability of the blood by lessening the proportion of its fibrin, and still later, when it appeared that the medicine directly diminished the proportion of red globules in the blood. The former effect was probably, indeed, only a consequence of the latter. But, although it seemed to be proved that mercury thus restricted inflammatory action and its consequences, it was not proved that their restriction by this means was necessary to cure the disease, and it was even rendered probable that the antiphlogistic use of calomel involved more danger than advantages. Extensive observation has now demonstrated that, with one or two possible exceptions, inflammatory affections may be cured quite as rapidly, and much more safely and agreeably, without mercury than with it, while the dangers involved in the antiphlogistic use of the medicine are so serious as to condemn it whenever a safer remedy can be substituted for it.

Of acute inflammations, for whose treatment calomel has been long supposed essential, may be mentioned *pericarditis*, *endocarditis*, *pleurisy*, *pneumonia*, *peritonitis*, *meningitis*, and *hepatitis*. It is now apparently determined that none of these diseases, as a rule, require calomel for their cure, and that most of them are aggravated by it. In regard to *peritonitis*, it may be added that as the disease is never idiopathic, at least in adults, and never primary unless traumatic, pathology confirms what clinical observation demonstrates—that mercury is unsuited to its cure. Acute *hepatitis* is not now, as formerly, indiscriminately treated by calomel in tropical climates, where alone the disease is frequently observed. The use of mercurial and of other purgatives appears to be beneficial in the early stage of the disease, but not through any specific operation. There are good grounds for suspecting that in hot climates the repeated administration of calomel in divided doses leads to the formation of abscess of the liver. *Meningitis*, like peritonitis, is always a secondary disease when not traumatic, depending upon a specific poison in epidemic cerebro-spinal meningitis, upon the rheumatic poison in another class of cases, upon tubercle in a third, etc. In no form of meningitis is calomel of any avail, unless it

may be so in certain exceptional cases of the tubercular variety; and, although it must be confessed that diagnostic difficulties obscure the subject, still, in the present state of our knowledge, mercury stands next to iodine in the promise of doing good. In regard to pleurisy, pneumonia, pericarditis, and endocarditis the case is somewhat different. In their acute forms mercury is probably unnecessary, and, considering its liability to abuse, should not be employed; but when their acute stage has passed and the products of inflammation show no tendency to be absorbed, mercury sometimes hastens this consummation in a remarkable degree, even when all other medicines have failed to abate the hectic or asthenic symptoms or diminish the physical evidences of the causes that produce them. Especially is this the case when the local lesion is engrafted, upon a syphilitic constitution. When under this dyscrasia alone the lung becomes solidified, simulating tubercular infiltration, a carefully-conducted course of mercury will often dissipate the local signs of disease and restore the general health. Calomel is worse than useless in acute articular *rheumatism*; it neither mitigates the disease nor prevents its complications. In certain cases of subacute and chronic rheumatism involving the ligaments of the joints and rendering the latter stiff and painful on motion, a course of very small doses of calomel will sometimes act beneficially; but more advantage may be derived from iodide of potassium. Several cases published by Dr. Ormsby illustrate the advantages of calomel in membranous *dysmenorrhœa* when given so as slightly to affect the gums (*Med. Record*, xx, 597). Simpson formerly attained the same end by means of pessaries medicated with mercurial ointment (*Clinical Lectures*, Amer. ed., 1863, p. 109). In *metritis*, both acute and chronic, calomel and opium are generally administered with supposed advantage. In diseases of the *kidney*, whether acute or chronic, mercury is a mischievous medicine. *Iritis*, although it may, in its simple form, recover without mercury, is more readily cured by calomel and opium internally, and mercurial ointment, with extract of belladonna or the instillation of atropia, topically. Syphilitic iritis should always be treated by the internal use of calomel, if not by mercurial inunctions.

In *jaundice* depending upon engorgement of the liver or upon obstruction of its ducts with thick bile saline purgatives are the appropriate remedies, but the English custom of first administering calomel or blue pill prevails in this country. It is very doubtful whether the mercurial renders the purgative treatment more efficient. It can do no harm as an occasional remedy, but is very mischievous if habitually taken.

Among mucous inflammations, *pseudo-membranous laryngitis*, or true croup (and not diphtheria, which we hold to be a totally different affection), is treated by calomel internally and by mercurial inunctions, in the belief that under its operation exudation-matter will form less densely and adhere less tenaciously, and hence be rejected by coughing or by vomiting more readily. The question of their efficacy is difficult to solve, for the cases of the disease differ widely among themselves in the thickness and tenacity of the membrane and in the extent of its deposit. But in a disease with such fatal tendencies even a doubtful remedy should not be rejected. In *syphilitic laryngitis*, which is generally ulcerative, calomel, or mercury in some form, is indispensable. In acute *bronchitis* which shows no tendency to decline at the usual period of subsidence small doses of calomel repeated until the mouth begins to feel its effects will often promote the cure; and in the chronic form of the same disease, with dyspnoea and bronchorrhœa depending upon thickening of the bronchial mucous membrane, the same method is often very efficient. In acute *dysentery* calomel has been used as a purgative and in small or so-called alterative doses. There appears to be no doubt that in the sthenic form of the disease purgative doses of calomel, if given in the forming stage, will modify the course of the disease, just as salines, rhubarb, and ipecacuanha will. There is no reason to attach any special importance to calomel as such. Its virtue resides chiefly in its mild evacuant and protective action. In this disease calomel in small or fractional doses is most useful when associated with ipecacuanha, and least so when combined with opium. The advantage of the latter combination consists mainly in its negative virtue of protecting the patient from perturbative measures. It is most suitable when the acute stage has begun to decline and after a judicious evacuant treatment has mitigated the severity of the attack. A similar remark is perhaps justifiable in regard to the calomel treatment of epidemic *cholera*. The huge doses of the drug which were originally used by the British East India surgeons have long ago been condemned, as well as the other elements of their crude therapeutics. If calomel has shown any special virtues in epidemic cholera, it has only been when it was administered in doses of 1 or 2 grains every 5 or 10 minutes, with 1 or 2 drops of laudanum in each of the first few doses. Knowing, as

we do, the utter loss by the stomach of its absorbing function in this disease, the method in question really amounts to a negative treatment, and this, it is pretty well settled, is more efficient than any of the active methods which have prevailed. The hostile influence of mercury upon the lower forms of animal life explains the propriety of using calomel purges in some cases of *lumbroid worms*. But the possibility of its poisonous action on the system renders it less eligible for this purpose than other direct vermicides.

It is perhaps even truer of calomel than of other mercurials, that it should be very cautiously exhibited to persons suffering under a scrofulous, tuberculous, or cancerous cachexia or to those who have begun to exhibit the infirmities of old age or who are known to be morbidly susceptible to its poisonous influence.

In an ointment—calomel ʒj, lard ʒj (Gm. 4 to Gm. 32)—calomel is sometimes applied locally in the treatment of limited *scaly eruptions*, and in powder it has been used to destroy *maggots* infesting wounds in hot weather. In the latter form also it has been applied to *ulcers of the cornea*, but is not strongly to be recommended for this purpose. Schlaefke warns against the application of calomel to the conjunctiva of patients taking iodide of potassium. This salt is then abundantly contained in the tears, and converts the calomel into iodate and iodide of mercury, which in solution exert a caustic action (*Med. News and Abst.*, April, 1880, p. 211).

Administration.—Calomel is most conveniently given mixed with a little syrup or enclosed in wafers. As a purgative *dose*, from 5 to 20 grains (Gm. 0.30–1.30) may be administered. Children require larger doses, in proportion to their age, than adults. To produce its constitutional action, of which the first sign is usually a metallic taste in the mouth or soreness of the gums, 1 or 2 grains (Gm. 0.05–0.10) may be given three times a day, with $\frac{1}{2}$ grain of opium; but still smaller doses, more frequently repeated, as $\frac{1}{10}$ or $\frac{1}{12}$ grain (Gm. 0.005–0.006) every hour, will affect the system more promptly.

HYDRARGYRI CYANIDUM, U. S.—CYANIDE OF MERCURY.

Hydrargyrum cyanatum, P. G.; *Hydrargyrum borussicum*, *Mercurius cyanatus s. borussicus*, *Cyanuretum hydrargyricum*.—*Mercuric cyanide*, *Cyanuret of mercury*, E.; *Cyanure (Bicyanure, Prussiate) de mercure*, Fr.; *Cyanquecksilber*, *Quecksilber-Cyanid*, G.

Formula HgCy_2 or $\text{Hg}(\text{CN})_2$. Molecular weight 251.7.

Cyanide of mercury should be kept in well-stopped bottles, protected from light.

Preparation.—The process recommended by the U. S. P. 1870 consists in dissolving oxide of mercury in hydrocyanic acid, the latter being prepared as the first step by acting upon potassium ferrocyanide with sulphuric acid. (See ACID. HYDROCYANICUM, page 66.) On agitating it with mercuric oxide a combination is effected, resulting in the production of mercuric cyanide and water; $2\text{HCy} + \text{HgO}$ yields $\text{HgCy}_2 + \text{H}_2\text{O}$. Should an excess of mercuric oxide be present, it will combine with the cyanide to mercuric oxycyanide, HgO.HgCy_2 , which is converted into cyanide by the addition of a reserved portion of hydrocyanic acid; an excess of the latter does not change the nature of the product, and is volatilized on evaporating the liquid. When the clear liquid has been sufficiently concentrated it is set aside in a cool and dark place to crystallize, and the crystals are dried, protected from the light.

This is not the only process, but the most convenient one, by which mercuric cyanide may be obtained. On boiling pure ferrocyanide of iron with mercuric oxide, mercuric cyanide enters into solution; should the filtrate contain iron, it must be evaporated to dryness, the residue again taken up with water, and the solution evaporated to crystallization. On boiling potassium ferrocyanide with a proper quantity of mercuric sulphate, a complex reaction will take place, resulting finally in the production of metallic mercury and of a solution containing mercuric cyanide, potassium sulphate, and ferric sulphate, to be separated by crystallization from diluted alcohol. $7\text{HgSO}_4 + 2\text{K}_4\text{FeCy}_6 = \text{Hg} + 6\text{HgCy}_2 + 4\text{K}_2\text{SO}_4 + \text{Fe}_2\text{SO}_4$.

Properties.—Mercuric cyanide is in colorless or white quadrangular prisms, which are odorless, have a bitter metallic taste, and are permanent in the air if the light be excluded. The salt is soluble at 15°C . (59°F .) in 12.8 parts of water (U. S., P. G.) and in 14.5 (P. G.) or 15 (U. S.) parts of alcohol, also in 3 parts of boiling water and in 6 parts of boiling alcohol, but is quite sparingly soluble in absolute alcohol. The solutions have a neutral reaction to test-paper. The aqueous solution is not decomposed by nitric or dilute sulphuric acid, but hydrochloric acid liberates hydrocyanic acid, recognizable by its odor, and mercuric chloride remains in solution; it yields a black precipitate with sulphuretted hydrogen, but does not give the ordinary reactions for mercuric

salt or cyanide when tested with alkalies, potassium iodide, or silver nitrate, double compounds, mostly crystalline, being formed, which are more or less freely soluble in water. The salt is blackened by exposure to the light, and when carefully dried and heated is decomposed into mercury and cyanogen, which is inflammable, burning with a purplish flame; but when rapidly and strongly heated the crystals decrepitate violently, and black paracyanogen is first produced before the whole is finally dissipated, and in the presence of moisture carbonic acid, ammonia, and hydrocyanic acid are evolved. When mixed with an equal weight of iodine and heated in a dry test-tube, two crystalline sublimates are obtained, the lower one consisting of mercuric iodide, being yellow and becoming red on cooling, while the upper one, consisting of cyanogen iodide, is white and has a penetrating acrid odor.

FIG. 151.

Crystal of Mercuric Cyanide.

Tests.—Mercuric cyanide dissolved in water should not impart a brown color to turmeric-paper (absence of mercuric oxycyanide). "A 5 per cent. aqueous solution of the salt, when mixed with a dilute aqueous solution of iodide of potassium, should not yield a red or reddish precipitate soluble in excess of either liquid (absence of mercuric chloride)." — *U. S.* In the presence of a little chloride this test is apt to fail unless the potassium iodide solution be very cautiously added. A much better test is the following: "The solution of the salt in 20 parts of water, slightly acidulated with nitric acid, should not produce a white precipitate on the addition of test solution of silver nitrate." — *P. G.* The absence of salts of other metals is shown by the complete volatility by heat.

Medical Action and Uses.—Cyanide of mercury is a violent irritant poison, producing also extreme prostration and local cyanosis, and death by exhaustion. In other words, its action includes that of hydrocyanic acid as well as that of the irritant mercurial salts. It has been used in the treatment of syphilis. A German physician claims that when all the usual remedies for diphtheria had failed he succeeded in curing nearly all his cases by administering every hour $\frac{1}{8}$ grain of cyanide of mercury (*Times and Gaz.*, Jan. 1881, p. 101). The share of the medicine in the alleged result is more than problematical. No sufficient reason appears for retaining so dangerous a preparation among official medicines. 20 grains (Gm. 1.30) of it caused death in 10 days, and 2 grains (Gm. 0.10) a severe illness which lasted for 3 weeks.

HYDRARGYRI IODIDUM RUBRUM, *U. S., Br.*—RED IODIDE OF MERCURY.

Hydrargrum biiodatum rubrum, P. G.; *Deutoioduretum (Biniodidum) hydrargyri*, *Mercurius iodatus ruber*, *Ioduretum hydrargyricum*.—*Biniodide of mercury*, *Mercuric iodide*, E.; *Deuto-iodure (Bi-iodure) de mercure*, *Iodure mercurique*, Fr.; *Rothes Jodquecksilber*, *Quecksilberjodid*, G.

Formula HgI_2 . Molecular weight 452.9.

Preparation.—Corrosive Chloride of Mercury 9 parts (540 grains); Iodide of Potassium 11 parts (660 grains); Distilled Water a sufficient quantity. Dissolve the corrosive chloride of mercury in 150 parts (150 drachms or 20 fluidounces) of warm distilled water, and the iodide of potassium in 30 parts (30 drachms or 4 fluidounces) of distilled water, and filter the solutions separately. Add the solution of corrosive chloride of mercury, when cold, to the solution of iodide of potassium, constantly stirring. Collect the precipitate on a filter, wash it with distilled water until the washings cease to give a precipitate with test solution of nitrate of silver, and dry it between sheets of bibulous paper at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stopped bottles. — *U. S.*

Take of perchloride of mercury 4 ounces; iodide of potassium 5 ounces; boiling distilled water 4 pints. Dissolve the perchloride of mercury in 3 pints, and the iodide of potassium in the remainder of the water, and mix the two solutions. When the temperature of the mixture has fallen to that of the atmosphere decant the supernatant liquor from the precipitate, and, having collected the latter on a filter, wash it twice with cold distilled water and dry it at a temperature not exceeding 212° F. — *Br.*

Mercuric chloride and potassium iodide, when mixed in the proportion of the weight of 1 molecule of the former to 2 of the latter salt, decompose each other into mercuric iodide, which precipitates, and potassium chloride, which remains in solution; $HgCl_2 + 2KI$ yields $HgI_2 + 2KCl$. The British and German Pharmacopœias use the two salts in

the proportion of 4 to 5, which is a slight excess of the potassium salt over the theoretical quantity, but is generally necessary in practice, owing to the small percentage of impurities always present in commercial iodide of potassium. But even if both salts be absolutely pure, the proportions of the U. S. P. are wrong, and the resulting iodide is apt to be contaminated with chloride. By calculation it is found that 4 parts of mercuric chloride require for complete decomposition 4.898 parts of potassium iodide, or 9 parts of the former require 11.02 parts of the latter salt. When following the first process given above the precipitate should be permitted to settle, and solution of potassium iodide should be dropped into the supernatant liquid as long as a turbidity is produced. Adding the mercuric chloride to the potassium iodide prevents the formation of a sparingly-soluble compound until the former salt is used in excess. By mixing the two solutions cold the red iodide is separated in the form of powder, but when the hot solutions are mixed and slowly cooled beautiful crystals are obtained. In either case the yield should be about 60 per cent. over the weight of the corrosive sublimate used.

Properties.—Mercuric iodide is a scarlet-red crystalline powder or is in brilliant crystals. It is permanent in the air if kept in the dark or in diffused daylight, but acquires a brownish tint in the sunlight. It is inodorous and nearly tasteless, a metallic taste being slowly developed when kept upon the tongue. On being heated to above 150° C. (302° F.), it turns yellow, but on cooling readily resumes its red color under various influences. It fuses near 240° C. (464° F.) to an amber-colored liquid, and at a higher heat sublimes to bright-yellow tabular crystals, which, after cooling, are again converted into the prismatic or octahedral red crystals. The salt is very sparingly soluble in cold or hot water, little so in ether and diluted nitric acid, but more freely soluble in hydriodic or hydrochloric acid, in potassium iodide or chloride, in many ammonium salts, in solutions of mercuric salts, in chloroform, fixed oils, hot carbon disulphide, etc. It dissolves in 130 parts of cold and in 15 (U. S.) or 20 (P. G.) parts of hot alcohol, crystallizing on cooling; on pouring the alcoholic solution into cold water the salt separates as a fine yellow powder, remaining suspended in the liquid and gradually turning red. The solutions are colorless, and are partly decomposed by potassa solution, a portion of the mercury being deposited as mercuric oxide, the remainder forming a soluble iodide of potassium and mercury. On heating the salt with solution of soda and glucose or sugar of milk, metallic mercury will be precipitated, and on heating it with sulphuric acid and black oxide of manganese, vapors of iodine will be given off. When a hot solution of potassium iodide is saturated with mercuric iodide and then allowed to cool, one-third of the latter salt crystallizes on cooling; the remainder is obtained, on further concentration, as yellow prisms, which are soluble in alcohol and ether, but are partly decomposed by water. The crystals are *mercuric potassium iodide* ($2\text{KI} \cdot \text{HgI}_2$) $3\text{H}_2\text{O}$, more generally known as *iodohydrargyrate of potassium*, and are likewise formed on adding mercuric chloride to an excess of potassium iodide.

Tests.—Impurities, if present, are readily detected by the residue left on subliming the salt (red oxide of lead and other non-volatile compounds) and on dissolving it in hot alcohol (vermilion, etc.). The cold alcoholic solution should be colorless and without acid reaction (mercuric chloride), and on the addition of ammonia should merely acquire a brown color, but not be precipitated (mercuric chloride). Distilled water, on being agitated with the salt and filtered, should not be affected by hydrosulphuric acid (metallic salts) nor by solution of silver nitrate (soluble chlorides, iodide, etc.).

Pharmaceutical Uses.—The observation of Nessler (1856) of the effect of ammonia upon solutions of mercuric iodide has resulted in the discovery of a very delicate reagent for minute quantities of ammonia or ammonia salts, known as the

Nessler Reagent.—It is made by dissolving 50 Gm. of potassium iodide in a little boiling distilled water, and adding to it, carefully, sufficient boiling hot concentrated solution of mercuric chloride until the red precipitate formed is no longer redissolved on agitation; the liquid is decanted and filtered, and the filtrate mixed with 200 Gm. of potassa dissolved in a small quantity of water; when cold the mixture is diluted to the measure of 1 liter by the addition of distilled water. The addition of 5 Ccm. of cold saturated solution of corrosive sublimate is recommended by some, but is not necessary. (See also *AQUA AMMONIÆ*, p. 235.) It will be observed that this is a solution of mercuric potassium iodide in caustic potassa. On the addition of ammonium salt this is decomposed by the potassa, ammonia is liberated, and reacts now with the double iodide and another portion of the potassa, resulting in the formation of brown insoluble dimereur-ammonium (NH_2) iodide, potassium iodide, and water, as will be seen from the equation $\text{NH}_3 + 2(\text{KI} \cdot \text{HgI}_2) + 3\text{KHO} = \text{NH}_2\text{I} + 5\text{KI} + 3\text{H}_2\text{O}$. If the ammonia is present in minute

quantity, the color is best observed by looking through the column of the liquid contained in a tall test-tube and placed on white paper.

Winckler (1830), Von Planta (1846), and Groves (1858) observed the behavior of solutions of the double iodide upon solutions of vegetable alkaloids, which led F. F. Mayer (1862) to the adoption of a tenth normal solution, now known as

Mayer's Solution.—It is prepared by dissolving 13.546 Gm. of mercuric chloride and 49.8 potassium iodide in sufficient distilled water to obtain 1 liter of liquid. The present test solution of iodide of mercury and potassium (see *List of Reagents*) is somewhat weaker, but otherwise almost identical with this. The test is applied in acidulated aqueous solutions, since ammonia would also be precipitated if an alkaline liquid was used. 1 Ccm. of this test liquid precipitates of

Aconitine, 0.0267 Gm.	Coniine, 0.00416 Gm.	Quinine, 0.0108 Gm.
Atropine, 0.0145 “	Morphine, 0.020 “	Quinidine, 0.0120 “
Brucine, 0.0233 “	Narcotine, 0.0213 “	Strychnine, 0.0167 “
Cinchonine, 0.0102 “	Nicotine, 0.00405 “	Veratrine, 0.0269 “

The end of the precipitation is determined by filtering a few drops of the liquid tested upon a watch-crystal, and by placing a small drop of the test solution alongside, allowing the two to run together. For colorless solutions which are free from chlorides, etc. an excess of the test liquid may be used, and the excess determined in the filtrate by a standard solution of silver nitrate.

Delffs' Reagent (1854) is a solution of potassium iodide saturated with mercuric iodide; its behavior to alkaloids appears to differ to a certain extent from the preceding.

Off. Prep.—*Liq. arsen. et hydrarg. iodidi*, *U. S.*; *Unguent. hydrarg. iodidi rubri*, *Br.*

Medical Action and Uses.—Biniodide of mercury is a powerful irritant poison; 2 grains (Gm. 0.12) of it taken with a drachm (Gm. 4) of iodide of potassium caused violent gastric pain, coma, stertor, opisthotonos, and convulsion. As an internal remedy it is superfluous, and dangerous unless very cautiously used. It may, however, be given in constitutional *syphilis* in a solution of iodide of potassium, and in the *dose* of $\frac{1}{16}$ grain (Gm. 0.004) cautiously increased. As a caustic it has been applied to the treatment of *lupus*, but is inferior to other preparations used for this purpose. It has also been employed in ointments in the proportion of 1 : 20, and from that to 1 : 5, as a stimulant or almost caustic application to *syphilitic diseases of the skin*, to chronic glandular indurations, fistulous *ulcers*, and chronic inflammation of the *joints*; in the proportion of 1 : 100 for granular eyelids, etc. This preparation has been administered subcutaneously. Yvon claims for the solution made according to the following formula that it does not irritate and that it is readily absorbed: Biniodide of mercury 1 Gm.; iodide of potassium 1 Gm.; neutral phosphate of soda 2 Gm.; distilled water 50 Ccm. (*Practitioner*, xxvii. 207).

HYDRARGYRI IODIDUM VIRIDE, *U. S.*, *Br.*—GREEN IODIDE OF MERCURY.

Hydrargyrum iodatum, *P. G.*; *Hydrargyrum iodatum flavum*, *Hydrargyri proto-ioduretum*, *Ioduretum hydrargyrosum*.—Yellow iodide or Proto-iodide of mercury, *Mercurous iodide*, *E.*; *Proto-iodure de mercure*, *Iodure mercuroux*, *Fr.*; *Quecksilberjodür*, *Gelbes Jodquecksilber*, *G.*

Formula Hg_2I_2 (or HgI). Molecular weight 652.6 (or 326.3).

Preparation.—Mercury 8 parts (400 grains); Iodine 5 parts (250 grains); Alcohol a sufficient quantity. Pour about 3 parts (150 grains or 3 fluidrachms) of alcohol into a mortar containing the mercury, add the iodine in several successive portions, and triturate the mixture, adding sufficient alcohol from time to time to keep the mass constantly moist, and taking care that it shall neither become too hot nor be exposed to light during the various steps of the process. Continue the trituration until all globules of mercury have disappeared and the mixture has become nearly dry and has acquired a greenish-yellow color. Then add sufficient alcohol to reduce the whole to a thin paste; pour this into a bottle, let it stand for several days, and then wash the iodide twice with about 50 parts (2500 grains or 6 $\frac{1}{2}$ fluidounces) of alcohol each time, and decant the washings. Transfer the iodide to a filter, and continue washing with alcohol until the washings are no longer affected by hydrosulphuric acid. Lastly, dry the product in a dark place between bibulous paper at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stopped bottles, protected from light.—*U. S.*

Take of mercury 1 ounce; iodine 278 grains; rectified spirit a sufficiency. Rub the

iodine and mercury in a porcelain mortar, occasionally moistening the mixture with a few drops of the spirit, and continuing the trituration until metallic globules are no longer visible and the whole assumes a green color. The product thus obtained should be dried in a dark room on filtering-paper by simple exposure to the air, and preserved in an opaque bottle.—*Br.*

Mercury and iodine are contained in mercurous iodide very nearly in the proportion 8 : 5, as directed by the United States and German Pharmacopœias; this gives a slight excess of mercury, amounting to less than 2.5 per cent. of the weight of the iodide. The French Codex directs the proportion 5 : 3, ensuring a still greater excess of mercury. The proportion used by the British Pharmacopœia is that of the atomic weights of the two elements. On bringing iodine and mercury together they unite, forming mercurous or mercuric iodide according to the proportions employed. It appears, however, that a portion of mercuric iodide is always formed, and, being poisonous, requires to be removed or reduced to mercurous iodide by long trituration. The former is the course adopted by the pharmacopœias, the British excepted, the removal being accomplished by washing the product with alcohol. Washing the product with solution of sodium chloride in place of alcohol has been proposed; but, while mercuric iodide is thereby dissolved, the mercurous iodide is perceptibly decomposed, particularly at a somewhat elevated temperature. Le Canu (1877) states the washing to be unnecessary if the mercury is first finely divided by trituration with a little alcohol before the iodine is added in small portions. But even in this case we would prefer the subsequent employment of alcohol to ensure the absence of the red iodide.

It has been repeatedly proposed to prepare mercurous iodide by double decomposition of calomel or other mercurous salt with iodide of potassium; the results, however, are never satisfactory, since by the action of the potassium salt some red iodide is formed and metallic mercury liberated. (See a paper in *Amer. Jour. Phar.*, 1857, p. 11.)

Properties.—Mercurous iodide which has not been washed with alcohol is dark green, but having been freed from the red iodide by either hot or cold alcohol it is greenish-yellow, and becomes gradually of a brighter yellow color. It is inodorous, tasteless, not crystalline when viewed under the microscope, and has the specific gravity 7.64. On exposure to the light, red iodide is formed; it turns dark-green, and finally black, the decomposition being accelerated by moisture. When heated it turns red-brown, and finally sublimes, without leaving any residue, yielding mercury and red crystals of mercurous-mercuric iodide, $\text{Hg}_2\text{I}_2 \cdot 2\text{HgI}_2$, which become yellow on cooling. Mercurous iodide is almost insoluble in water and entirely insoluble in alcohol and ether; it dissolves in ammonia, leaving a gray residue; in potassium iodide, leaving mercury and yielding a solution of mercuric potassium iodide; in sodium hyposulphite, leaving mercury and yielding a colorless liquid which on heating deposits dark-red mercuric sulphide.

Tests.—After shaking 1 Gm. of the salt with 10 Ccm. of alcohol the filtrate should be scarcely colored by hydrosulphuric acid; on being dropped into water it should produce only a very faint cloudiness, and on evaporation should leave only a minute trace of red iodide. Fixed impurities, if present, remain behind if a portion is heated to redness in a porcelain crucible.

Medical Action and Uses.—Green iodide or protiodide of mercury is chiefly used in the treatment of constitutional *syphilis*, and is preferred above other preparations by several eminent syphilographers. It should be given in doses of from $\frac{1}{4}$ to 1 grain (Gm. 0.04–0.06) three times a day, and gradually increased until these doses are trebled or more, provided that neither salivation nor diarrhoea occurs. It is less apt than calomel to produce such effects. The following formula is much employed: $\mathcal{R}$. Protiodide of mercury, extract of lettuce, each 45 grains (Gm. 3); extract of opium 15 grains (Gm. 1); confection of roses 90 grains (Gm. 6). Mix, and divide into sixty pills, one, two, or three to be taken daily.

HYDRARGYRI OXIDUM FLAVUM, U. S., Br. Add.—YELLOW OXIDE OF MERCURY.

Hydrargyrum oxydatum via humida paratum, P. G.; *Hydrargyrum oxydatum præcipitatum* (vel flavum).—Precipitated oxide of mercury, or Mercuric oxide, E.; *Oxyde mercurique jaune* (précipité), *Deutoxyde jaune de mercure*, Fr.; *Præcipitirtes* (Gelbes) *Quecksilberoxyd*, G.

Formula HgO . Molecular weight 215.7.

Preparation.—Corrosive Chloride of Mercury 1 part (2 oz. av.); Solution of

Potassa 9 parts (18 oz. av. or 17 fluidounces); Distilled Water a sufficient quantity. Dissolve the corrosive chloride of mercury in 100 parts (200 oz. av. or 12 pints) of warm distilled water and filter the solution. Pour the filtrate into the solution of potassa, previously diluted with 100 parts (200 oz. av. or 12 pints) of distilled water, stirring constantly. Set the liquid containing the precipitate aside for 24 hours. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by the affusion and decantation of distilled water, using about 100 parts (200 oz. av. or 12 pints) of water each time. Continue the washing on a strainer until the washings cease to be affected by test solution of nitrate of silver. Let the precipitate drain, and dry it between bibulous paper in a dark place at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stopped bottles, protected from light.—*U. S.*

Take of perchloride of mercury 4 ounces; solution of soda 2 pints; distilled water a sufficiency. Dissolve the perchloride of mercury in 4 pints of distilled water, aiding the solution by the application of heat, and add this to the solution of soda. Stir them together; allow the yellow precipitate to subside; remove the supernatant liquor by decantation; thoroughly wash the precipitated oxide on a calico filter with distilled water, and finally dry it by the heat of a water-bath.—*Br.*

On mixing solutions of mercuric chloride and potassa of soda, sodium chloride, water, and mercuric oxide are formed, the latter being precipitated; $\text{HgCl}_2 + 2\text{HKO}$ yields $2\text{KCl} + \text{H}_2\text{O} + \text{HgO}$. The alkali must be in excess, lest some mercuric oxychloride be precipitated with the oxide, and it is advisable to pour the mercuric solution into the alkali. 9 parts of potassa solution of 5 per cent. contain .45 part of KHO , while theory requires .414 part for the mercuric chloride ordered, or an excess of a little over 8 per cent. This is ample, provided the potassa solution be free from carbonate or nearly so, otherwise brown mercuric carbonate would also be precipitated. The dilution of the liquids ordered by the U. S. P. is excessive; 1 part of mercuric chloride to 20 parts of water gives a sufficiently diluted solution, that of the German Pharmacopœia being 1:10. Of great importance for the appearance of the oxide is the temperature at which it is prepared; the lower it be kept the brighter will be the yellow color, while with an elevation of temperature the red tint will become more decided. The German Pharmacopœia allows 30° C. (86° F.) as the highest limit during all stages of the process. The yield is about 0.79 part (a little over $1\frac{1}{2}$ oz. av.).

Properties and Tests.—Yellow mercuric oxide is a heavy, smooth, impalpable, amorphous, yellow or reddish-yellow powder, which is not altered in the air, but on exposure to light becomes dark, in consequence of partial reduction to mercurous oxide; when heated it assumes a red color, and at a sufficiently strong heat is decomposed and volatilized like red mercuric oxide. It has the specific gravity 11.0, is without odor or taste, and is insoluble in water and other simple solvents, but dissolves readily and completely without effervescence in diluted hydrochloric or nitric acid. When digested or agitated with a solution of oxalic acid it forms white mercuric oxalate (difference from red oxide). Heated with an alcoholic solution of mercuric chloride, it speedily turns black from the formation of an oxychloride; red mercuric oxide slowly undergoes a similar change (Roucher). It should be completely volatilized by heat, and its solution in diluted nitric acid should become merely opalescent on the addition of test solution of silver nitrate.

Off. Prep.—Oleatum hydrargyri, Unguent. hydrarg. oxidi flavi, *U. S.*

Medical Uses.—This preparation is used only as an external remedy to stimulate indolent ulcers, especially of venereal origin, and as an application in granular and ulcerated conditions of the eyes. It is applied chiefly in an ointment, which is official.

HYDRARGYRI OXIDUM RUBRUM, *U. S., Br.*—RED OXIDE OF MERCURY.

Hydrargyrum oxydatum, P. G.; *Hydrargyri nitrico-oxidum*, *Mercurius corrosivus* (*precipitatus*) *ruber*, *Oxydum hydrargyricum*.—Peroxide of mercury, Red precipitate, Red mercuric oxide, *E.*; Deutoxide (*Peroxyde*) rouge de mercure, Oxyde mercurique, Précipité rouge, Poudre de Jean de Vigo, *Fr.*; *Roth's Quecksilberoxyd*, *Rother Präcipitat* (*Quecksilber-Präcipitat*), *G.*

Formula HgO . Molecular weight 215.7.

Preparation.—Take of Mercury, by weight, 8 ounces; Nitric Acid $4\frac{1}{2}$ fluidounces; Water 2 fluidounces. Dissolve half the mercury in the nitric acid diluted with the water, evaporate the solution to dryness, and with the dry salt thus obtained triturate the remainder of the mercury until the two are uniformly blended together. Heat the mixture in

a porcelain dish, with repeated stirring, until acid vapors cease to be evolved, and when cold enclose the product in a bottle.—*Br.*

In this process nitrate of mercury is formed as the first step; this may be directly decomposed by heat, or, as directed above, it is previously mixed with an additional quantity of mercury, which, during the subsequent heating, is oxidized at the expense of the nitrate. In both cases the color changes to yellow and then to red, red fumes of nitric peroxide being given off. Occasionally a minute quantity of nitrate remains undecomposed. The decomposition is as follows: $2(\text{Hg}_2\text{NO}_3) + \text{Hg}_2 = 4\text{HgO} + 2\text{N}_2\text{O}_4$. Should the nitric acid employed be contaminated with hydrochloric acid, a corresponding quantity of mercuric chloride, and finally oxychloride, would be formed, the latter remaining with the mercuric oxide as an impurity. The last traces of acid may be removed by boiling with diluted soda solution.

Properties.—When made on a small scale it is a finely granular powder of a yellowish-red color without lustre, but made in larger quantities it is obtained in the form of bright brownish-red shining crystalline scales, which on trituration yield a fine orange-red powder, the yellow tint increasing with the fineness of the powder. It is inodorous, and at first tasteless, but slowly develops a metallic taste. It is insoluble in water and other simple solvents, but completely soluble in diluted hydrochloric and nitric acids. It is permanent in the air if kept in the dark, but on exposure to light it becomes superficially black—however, much more slowly than the yellow oxide. When heated its color is changed to dark-red, brown, and near 400°C . (750°F .) to black, the original color reappearing on cooling; but at a red heat it is completely decomposed into metal and oxygen.

Tests.—When strongly heated, mercuric oxide should not give off red nitrous vapors (absence of nitrate), and when heated to full redness it should be decomposed and volatilized, without leaving any residue (absence of non-volatile impurities). On being agitated or digested with a solution of oxalic acid in 10 parts of water, the red color should not be changed (difference from yellow mercuric oxide). Treated with diluted nitric acid in excess, it should yield a colorless solution. A red-colored residue would indicate the presence of brick-dust or of vermilion, the latter being volatilizable by heat; a brown residue (of puce-colored oxide of lead) would prove an adulteration with red lead, and the nitric acid solution would contain lead, recognizable by the white precipitate appearing on the addition of a little sulphuric acid. The nitric acid solution should remain undisturbed or merely become faintly opalescent on the addition of test solution of silver nitrate (absence of chloride). If to 1 Gm. of red mercuric oxide 5 Ccm. of water be added, followed by 5 Ccm. of sulphuric acid, and after cooling 1 Ccm. of concentrated solution of ferrous sulphate be carefully poured upon the acid mixture, a brown color should not be produced between the two liquids (absence of nitrate).

The preparation formerly officinal in various pharmacopœias as *Mercurius præcipitatus per se* or *Mercurius calcinatus* was red oxide of mercury in the form of crystalline scales, which are obtained by keeping metallic mercury in a loosely-covered flask or retort at a temperature near its boiling-point. The process required several weeks for its completion.

Off. Prep.—Unguentum hydrarg. rubri, *U. S., Br.*

Medical Action and Uses.—Red precipitate is a powerful irritant, and taken internally may act as a corrosive poison. Its application to ulcers, wounds, etc. has been frequently followed by its constitutional operation, including salivation. The last-named effect is said to be unusual when the medicine is administered internally, as it sometimes has been in the treatment of *syphilis*, in the dose of one-tenth of a grain (Gm. 0.006) twice a day and gradually increased. Externally, it is generally used in the form of an ointment, but sometimes it is also applied as a fine powder, mixed with sugar, to indolent *syphilitic ulcers*, *condylomata*, etc., and even to *granular eyelids*, *pannus*, *ulcers*, and *opacities of the cornea*. But for the latter purposes the officinal ointment of red precipitate is generally preferable. A mixture of 1 part of red oxide of mercury with 50 parts of finely-powdered white sugar was much used by Trousseau as a snuff in cases of *ozæna*, especially when of syphilitic origin. Before it is applied the nostrils should be cleansed by the nasal douche.

HYDRARGYRI SUBSULPHAS FLAVUS, U. S.—YELLOW SUBSULPHATE OF MERCURY.

Hydrargyri sulphas flava, U. S. 1870; *Hydrargyri subsulphas*, *Hydrargyrum sulphuricum flavum*, *Mercurius emeticus flavus*, *Sulphas hydrargyricus flavus*, *Turpethum minerale*.—*Basic mercuric sulphate*, *Oxymercuric sulphate*, *Subsulphate of mercury*, *Turpeth mineral*, E.; *Sulfate trimercurique*, *Sulfate jaune de mercure*, *Turbith minéral*, Fr.; *Basisches Quecksilberoxydsulfat*, *Mercurioxydsulfat*, *Mineralischer Turpeth*, G.

Formula $2\text{HgO} \cdot \text{HgSO}_4 = \text{Hg}(\text{HgO})_2\text{SO}_4$. Molecular weight 727.1.

Preparation.—Mercury 10 parts (5 oz. av.); Sulphuric Acid 5 parts ($2\frac{1}{2}$ oz. av.); Nitric Acid 4 parts (2 oz. av.); Distilled Water a sufficient quantity. Upon the mercury, contained in a capacious flask, pour the sulphuric acid, then gradually add the nitric acid previously mixed with 3 parts ($1\frac{1}{2}$ ounces) of distilled water, and digest at a gentle heat until reddish fumes are no longer given off. Transfer the mixture to a porcelain capsule, and heat it on a sand-bath, frequently stirring, until a dry, white mass remains. Reduce this to a fine powder, and throw it, in small portions at a time and constantly stirring, into 200 parts (100 oz. av. or 6 pints) of boiling distilled water. When all has been added continue the boiling for 10 minutes, then allow the mixture to settle, decant the supernatant liquid, transfer the precipitate to a strainer, wash it with warm distilled water until the washings no longer have an acid reaction, and dry it in a moderately warm place.—U. S.

Mercuric sulphate is formed by the action of hot sulphuric acid upon metallic mercury, the combination being effected with decomposition of a portion of the sulphuric acid (see HYDRARGYRI SULPHAS), or, as in the above process, with decomposition of nitric acid; $\text{Hg}_2 + 2\text{H}_2\text{SO}_4 + 2\text{HNO}_3$ yields $2\text{HgSO}_4 + 3\text{H}_2\text{O} + \text{N}_2\text{O}_3$. On adding this normal sulphate to boiling water it is converted into basic sulphate, while an acid sulphate remains in solution. The result varies somewhat, depending upon the amount and the temperature of the water. Using boiling water in the above proportions, the yield will be about 75 per cent. of the weight of the dry mercuric sulphate used. The same compound is also formed by slowly pouring a solution of mercuric nitrate into an excess of a boiling solution of sodium sulphate.

Properties.—Yellow subsulphate of mercury is a heavy bright lemon-yellow powder which has the specific gravity 6.44, is permanent in the air, inodorous, has a slight metallic taste, on heating becomes red, and yellow again on cooling; at a red heat it is completely volatilized, being at the same time decomposed into metallic mercury, oxygen, and sulphurous acid. It is insoluble in alcohol and ether, requires 2000 parts of cold and 600 parts of boiling water for solution (Fourcroy), is decomposed by potassa solution, yellow mercuric oxide being formed, and dissolves completely in sulphuric, nitric, or hydrochloric acid, the latter solution, according to Mohr, containing corrosive sublimate and free sulphuric acid.

Tests.—“The salt should be soluble in 20 parts of hydrochloric acid without residue (absence of mercurous salt).”—U. S. Lead, if present, will likewise remain undissolved. The presence of nitrate is detected by sulphuric acid and ferrous sulphate in the same manner as stated for red mercuric oxide. Non-volatile impurities are left behind on heating to bright redness.

Medical Action and Uses.—Turpeth mineral is a powerful irritant, and in sufficient doses may act as a corrosive poison, causing active erosion of the fauces, œsophagus, and stomach, and even sloughing of the first-named parts, as well as salivation. Several fatal cases of its use are recorded (STILLÉ, *Therapeutics*, 4th ed. ii. 769). In a recent instance a healthy child five months old died poisoned by about 5 grains of this preparation 11 hours after taking it. The reporter of this case refers to another with a like fatal issue (McPhedran, *Med. News*, xliii. 682). Drs. Randolph and Roussel report the cases of five men, each of whom had at first 5 grains, and later 3 grains, of the medicine. All of the patients were poisoned, but at last recovered. One of them was badly salivated (*Med. News*, xlv. 275). In spite of its grave effects, turpeth mineral has been used as an emetic in “croup,” by which was probably meant *spasmodic laryngitis*. The employment of so dangerous a remedy in a disease which involves no danger to life is inexcusable. The emetic action of this preparation is the first stage of its poisonous operation. The dose fitted to produce that effect is from 2 to 3 grains (Gm. 0.13–0.20) for a child. Owing to its tendency to salivate, it should not be employed as an errhine. It seems to be a superfluous article of the *materia medica*.

HYDRARGYRI SULPHAS, *Br.*—SULPHATE OF MERCURY.

Hydrargyrum sulphuricum, Mercurius vitriolatus, Sulfas mercuricus.—Persulphate of mercury, *Mercuric sulphate*, E.; *Deuto-sulfate (Persulfate) de mercure, Sulfate mercurique*, Fr.; *Schwefelsaures Quecksilberoxyd, Mercurisulfat*, G.

Formula HgSO_4 . Molecular weight 295.7.

Preparation.—Take of mercury, by weight, 20 ounces; Sulphuric Acid 12 fluid-ounces. Heat the mercury with the sulphuric acid in a porcelain vessel, stirring constantly until the metal disappears, then continue the heat until a dry white salt remains.—*Br.*

Mercury does not dissolve in cold sulphuric acid, but on heating the mixture sulphuric acid and watery vapors are disengaged, any excess of sulphuric acid is driven off, and the residue consists of mercuric sulphate; $\text{Hg}_2 + 4\text{H}_2\text{SO}_4$ yields $2\text{SO}_2 + 4\text{H}_2\text{O} + 2\text{HgSO}_4$.

Properties and Tests.—Mercuric sulphate is a heavy white crystalline powder which, on being mixed with a small quantity of water, is at first colored yellow, but after some time is converted into colorless shining prisms or silvery scales of the hydrated salt, $\text{HgSO}_4 \cdot \text{H}_2\text{O}$. A larger quantity of water decomposes it permanently into yellow basic sulphate. When heated to redness it is decomposed into mercury, oxygen, sulphurous acid, and mercurous sulphate, and is finally completely volatilized.

Pharmaceutical Uses.—It is employed for the preparation of turpeth mineral, corrosive sublimate, and calomel.

It is not used in medicine.

HYDRARGYRI SULPHIDUM RUBRUM, *U. S.*—RED SULPHIDE OF MERCURY.

Hydrargyri sulphuretum rubrum, U. S. 1870; Hydrargyrum sulfuratum rubrum; Cinnabaris, Sulfuretum hydrargyricum.—Red sulphuret of mercury, *Cinnabar, Vermilion, Paris red*, E.; *Sulfure rouge de mercure, Cinnabre*, Fr.; *Roths Schwefelquecksilber, Quecksilbersulfid, Zinnober*, G.

Formula HgS . Molecular weight 231.7.

Preparation.—Take of Mercury 40 troyounces; Sublimed Sulphur 8 troyounces. To the sulphur, previously melted, gradually add the mercury, with constant stirring, and continue the heat until the mass begins to swell. Then remove the vessel from the fire and cover it closely to prevent the contents from inflaming. When the mass is cold rub it into powder and sublime.—*U. S. 1870.*

The preparation of vermilion is carried on in large establishments, and will hardly ever be attempted by the pharmacist except as an experiment. It may be obtained in the dry or humid way. The above process belongs to the former class, but a large excess of sulphur is directed, $6\frac{1}{2}$ troyounces being sufficient for the quantity of mercury; the excess is volatilized before the cinnabar is condensed. If the black mass obtained in the first part of this process is digested with solution of potassa and potassium sulphuret at a temperature of about 45°C . (113°F .), it will be gradually converted into vermilion. This is also produced by digesting white precipitate with a solution of sulphur in ammonium sulphide or of sodium hyposulphite.

Cinnabar, native as well as artificially prepared, has been known from a remote period. Although in the early part of the eighteenth century it was stated to consist solely of mercury and sulphur, this was not conclusively proven until the beginning of the present century. Fuchs afterward showed that it has the same composition as the amorphous black mercuric sulphide, differing from it in being crystalline.

Properties.—Sublimed mercuric sulphide forms brilliant dark-red crystalline masses having a fibrous fracture; after levigation it is seen in commerce in the form of a bright scarlet-red, fine, inodorous, and tasteless powder. It has the spec. grav. 8.12, acquires a darker color on exposure to the sunlight, but remains unaltered in the dark. When heated to above 250°C . (482°F .) it becomes brown, then black, and finally volatilizes, and assumes its red color again on cooling; heated in contact with the air, it burns with a blue flame, emitting the odor of sulphurous acid. It is insoluble in water, alcohol, ether, hydrochloric or nitric or diluted sulphuric acid, cold concentrated sulphuric acid, or diluted alkaline solutions. Nitro-muriatic acid dissolves it without heat, with the separation of sulphur and the production of sulphuric acid and mercuric chloride. It dissolves in boiling sulphuric acid, forming mercuric sulphate and separating sulphur;

also in alkali sulphides containing potassa or soda. Metallic mercury is separated by heating vermilion with soda to redness; by boiling with water and iron or zinc; by zinc and warm diluted sulphuric acid, etc.

Tests.—Its complete volatility by heat ensures the absence of red lead and basic lead chromate (American vermilion); and when it is treated with warm solution of potassa the colorless solution, on being acidulated, should not yield a yellow or orange precipitate (absence of arsenic or antimony), nor should it produce a colored precipitate with acetate of lead (absence of chromates, iodides, or other sulphides). If agitated with warm diluted nitric acid, it should not turn brown (absence of red lead), nor should the filtrate be colored or become dark-colored on the addition of hydrosulphuric acid (lead) or of ammonia and ammonium sulphide (iron).

HYDRARGYRI SULPHURETUM NIGRUM, s. *Ethiops mineralis*. This preparation has been very properly discarded by the United States and British Pharmacopœias, but is still employed on the continent of Europe. It is made by triturating equal weights of mercury and sulphur until all metallic globules have disappeared. It forms a fine black and heavy powder, which, when viewed with a lens, does not show any globules of uncombined mercury. When heated upon a plate it takes fire and burns with a blue flame, without leaving any residue; heated in a test-tube, it yields a red sublimate of vermilion. When digested with hydrochloric acid, the acid liquid does not yield a white precipitate on being diluted with water (absence of antimony). *Ethiops mineralis* is a mixture of black amorphous sulphide of mercury, HgS , with a large excess of sulphur. Triturated with an equal weight of sulphide of antimony, *ethiops antimonialis* is obtained.

Medical Action and Uses.—The red, like other metallic sulphides, is less irritating than the sulphates of the same metal. Indeed, there is much reason for believing that in its natural state it has no action at all. It is seldom used, and then only by fumigation, powdered cinnabar being strewn upon hot coals; the sulphuret is decomposed, and the fumes contain metallic mercury and sulphurous acid. The irritating action of the latter renders the method objectionable. As occasionally employed, the patient is enclosed in a wooden box with an aperture through which his head passes, so that he is not obliged to inhale the irritating fumes. This method is said to be a very efficient one, although not without the risk of salivating, causing congestion of the brain, etc.

Black sulphuret of mercury is no longer official in the German Pharmacopœia, and its activity as a mercurial has been doubted. It was considered to be especially adapted to persons of delicate constitution or feeble health, and was given in (relatively) very large doses, such as from 5 to 20 grains several times a day.

HYDRARGYRUM TANNICUM OXYDULATUM, the tannate of the protoxide of mercury, has been proposed by Lustgarten as a substitute for other mercurials in the treatment of syphilis, etc. In the dose of from 3 to 5 gr. (Gm. 0.25–0.30) a day it appears as mercury in the urine after the lapse of 24 hours. It does not salivate or disturb the stomach or bowels. In ten cases of various forms of constitutional *syphilis* its effects were quite as favorable as those of mercurial ointment (*Centralblatt f. d. ges. Ther.*, ii. 93).

HYDRARGYRUM, U. S., Br., P. G.—MERCURY.

Hydrargyrum vivum, Mercurius vivus, Argentum vivum.—Quicksilver, E.; *Mercur*, Vif-argent, Fr.; *Quecksilber*, G.

Symbol Hg. Atomicity bivalent. Atomic weight 199.7.

Origin.—Mercury became known before the Christian era, but long after silver and gold had been in use. It is principally obtained from New Almaden in California, from Peru, China, Idria in Austria, and Almaden in Spain. It is found to some extent in the metallic state in the form of minute or large globules, also in combination with oxygen, chlorine, selenium, etc.; but the principal ore for extracting it is *cinnabar*. 38,250 pounds of mercury were imported into the United States in 1877, and 597,898 pounds in 1882.

Preparation.—Most of the mercury is obtained by roasting the ore in a kiln. It is placed upon an arch of brickwork containing several openings, through which the flames pass, whereby the sulphur of the ore is ignited and burns, air being admitted at the same time; the heat thus produced volatilizes the mercury, the vapors of which, mingled with the smoke and sulphurous acid gas, are passed through a series of condensing-chambers, where the metal is condensed, the incondensable gases finally escaping through the flue. This is essentially the process as carried on at Idria and New Almaden:

likewise at Almaden, except that the vapors are passed through the so-called *aludels*, consisting of cylinders adapted to each other, first in a descending and then in an ascending direction, where most of the mercury is condensed and collects in a gutter placed under the angle, the remainder being condensed in a large terminal chamber, from which the gases pass into the flue. In the Palatinate the cinnabar is mixed with lime, and in Bohemia with hammerslag, and then distilled, sulphide of calcium remaining behind in the former, and sulphide of iron in the latter, case.

Mercury appears in commerce in cylindrical iron flasks containing 75 pounds each. In this condition it still contains small quantities of other metals, principally lead, which, however, do not interfere with its uses in the silvering of looking-glasses, in the amalgamation process for the extraction of gold and silver, nor in the preparation of some chemicals. For barometers and thermometers, as well as for some pharmaceutical preparations, a purification of the metal is required or advisable, and may be effected by distillation or by the following process directed in several European pharmacopœias:

HYDRARGYRUM DEPURATUM, S. PURIFICATUM. Take of Mercury 100 parts; Nitric Acid, Distilled Water, each 5 parts. Digest in a suitable vessel for 3 days, shaking frequently. Having poured off the acid liquid, wash well the mercury with distilled water, and dry it completely.

The operation is best conducted in a broad glass or porcelain vessel, so as to expose a very large surface of the metal to the action of the dilute acid; or, as proposed by L. Meyer, by allowing the mercury to run slowly in a fine stream into a long glass tube containing the diluted acid. Lead, iron, and other metals, being far more easily oxidized and dissolved than the mercury, are thereby removed, though a little of the latter likewise passes into solution. After washing, most of the water may be removed by bibulous paper. These metals may also be removed by agitating the crude mercury with concentrated sulphuric acid or with solution of ferric chloride, the latter process being preferable for operations on a small scale.

Properties.—Mercury is solid at a temperature of -39.44° C. (-39° F.), and crystallizes in octahedrons and needles, which are ductile and may be cut with a knife. At the ordinary temperature it forms a bright silvery, lustrous, inodorous, and tasteless liquid, which is very cohering, and not adhering to glass or paper unless it be impure, when small globules will *tail* or leave a streak upon it. When triturated with sugar, fat, various salts, oil of turpentine, etc., it is converted into a gray powder consisting of minute globules separated by the foreign substances and running together again on their removal; this finely-divided state is called the *extinction* or *killing* of mercury, and is accomplished in making mercurial ointment and several other official preparations. Mercury has at 4° C. (39.2° F.) the specific gravity 13.59, and at 15° C. (59° F.) 13.57. It boils at about 357.2° C. (675° F.), giving a colorless vapor of 6.98 spec. grav., and leaving no residue; it volatilizes very slowly even at the ordinary temperature. It is permanent at the ordinary temperature, the whitish pellicle which forms upon the surface of commercial mercury being due to the presence of foreign metals (lead, zinc, etc.). It unites directly with chlorine, bromine, and iodine, and dissolves completely even in dilute nitric acid, with the evolution of nitric oxide. All simple solvents and boiling hydrochloric and dilute sulphuric acids are without action upon it, but hot concentrated sulphuric acid dissolves the metal, sulphurous acid being given off. When heated to near its boiling-point in contact with the atmosphere it combines with oxygen, forming scales of red oxide.

Tests.—The purity of mercury is ascertained from its behavior and properties as described above. When mercury is agitated for a few minutes with the official solution of ferric chloride, which is free from ferrous chloride, the liquid should afterward not yield a blue precipitate on the addition of potassium ferridecyanide, which would result through the solution of a foreign metal and the reduction of some ferric to ferrous chloride; nor should the liquid, if necessary, after being acidulated with hydrochloric acid yield more than a mere trace of a colored precipitate on the addition of hydrogen sulphide. Hager's test for distinguishing the purified from crude mercury has been adopted by the U. S. P., as follows: "On boiling 5 Gm. of distilled water with 5 Gm. of mercury, and 4.5 Gm. (1.5 Gm., Hager) of hyposulphite of sodium in a test-tube for about 1 minute, the mercury should not lose its lustre, and should not acquire more than a slightly yellowish shade (absence of more than slight traces of foreign metals)."

Oxides and Salts.—Mercury unites with oxygen in two proportions, and forms two series of salts, the *mercurous* and *mercuric*. All soluble salts of mercury are poisonous, have a strongly metallic taste, and mostly an acid reaction upon test-paper. The normal salts are usually white, and the basic salts yellow; treated with stannous chloride, phos-

phorous or sulphurous acid, or other deoxidizing agents, they are blackened, and finally reduced to metal. Their solutions deposit a silvery coating of metallic mercury upon a bright piece of metallic copper, and yield black precipitates with sulphuretted hydrogen and white ones with sodium phosphate. *Mercurous* salts yield black precipitates with potassa, ammonia, and, on boiling, also with alkaline carbonates. Hydrochloric acid causes a white precipitate of calomel, and potassium iodide separates a greenish-yellow deposit. *Mercuric* salts yield with potassa or soda, if added in insufficient quantity, brown-red, and if added in excess yellow, precipitates—with ammonia and ammonium carbonate white, and with potassium or sodium carbonate red-brown, precipitates. Hydrochloric acid does not disturb the solutions; potassium iodide causes a scarlet-red precipitate, which is soluble in an excess of either solution. All compounds of mercury are either volatilized or decomposed by heat.

Pharmaceutical Uses.—The following chemical compounds of mercury are official: Hydrarg. chlorid. corros. (perchloridum), Hydrarg. chlorid. mite (subchloridum), *U. S.*, *Br.*; Hydrarg. cyanidum, *U. S.*; Hydrarg. iodium rubrum, Hydrarg. iodium viride, Hydrarg. oxidum flavum, Hydrarg. oxid. rubrum, *U. S.*, *Br.*; Hydrarg. sulphas, *Br.*; Hydrarg. subsulphas flavus, Hydrarg. sulphuretum rubrum, *U. S.*; Hydrargyrum ammoniatum, *U. S.*, *Br.*; also the solutions: Liquor arsenici et hydrarg. iodidi, *U. S.*; Liquor hydrarg. nitratis (nitratis acidus), *U. S.*, *Br.*; Liquor hydrarg. perchloridi, *Br.*

The following pharmaceutical preparations contain mercury, chiefly uncombined: Emplast. ammoniaci cum hydrargyro, Empl. hydrargyri, Hydrargyrum cum creta, *U. S.*, *Br.*; Linim. hydrargyri, *Br.*; Massa (Pilula) hydrargyri, *U. S.*, *Br.*; Suppositoria hydrargyri, *Br.*; Unguentum hydrargyri, *U. S.*, *Br.*; Unguentum hydrarg. comp., *Br.*

The following pharmaceutical preparations contain combined mercury: Lotio hydrarg. flava, Lotio hydrarg. nigra, *Br.*; Pilul. antimonii comp. (hydrarg. subchloridi comp.), *U. S.*, *Br.*; Pilul. cathartica comp., *U. S.*; Unguent. hydrarg. ammoniati, *U. S.*, *Br.*; Unguent. hydrarg. iodidi rubri, *Br.*; Unguent. hydrarg. nitratis, *U. S.*, *Br.*; Unguent. hydrarg. oxidi flavi, *U. S.*; Unguent. hydrarg. oxidi rubri, *U. S.*, *Br.*; Unguent. hydrarg. subchloridi, *Br.*

Metallic writing-pencils have been prepared by melting together bismuth 90 parts and lead 70 parts, then adding mercury 8 parts, and casting in suitable moulds. By increasing the proportion of lead and mercury softer pencils, producing darker marks, are obtained.

Physiological Action.—In the following account we shall consider the action and uses of metallic mercury, and the effects which are common to it and a certain number of the compounds of the metal, referring the reader to those compounds for a description of their special operations:

On Animals: It has always been well known that mercury in every form is destructive of life in plants, insects, and small animals, and that its vapors prevent the development of the embryo in seeds and eggs. In the neighborhood of furnaces for smelting mercurial ores animals become cachectic, cows abort, and fish in contaminated streams lose their natural color. It has also long been known that mercury rubbed into the skin of an animal may destroy its life after having deranged all the functions, and may be extracted from the secretions during life and from the blood and tissues after death. Injected into the veins, it accumulates in the lungs on the venous side of the pulmonary circulation, and occasions there the formation of small abscesses; a similar effect in remote portions of the body is produced by the injection of metallic mercury into the arteries. The experiments of Von Mering upon animals in 1881 plainly showed an identity of the effects of mercury in them and in the human race (*Archiv f. experiment. Pathol.*, etc., xiii, 86). In *acute* poisoning gastro-intestinal phenomena were prominent, including profuse watery and bloody stools, with tormina and tenesmus, and sometimes vomiting. Salivation was usual, but not invariable. The respiration was irregular and jerking, the muscular power greatly reduced, and in several cases tremor and excitability existed. Death was caused mainly by exhaustion, but sometimes occurred suddenly. The primary phenomena of the *chronic* form of mercurial poisoning were those of stomatitis: the mucous membrane of the mouth and the gums became swollen, the tongue was indented by the teeth, and the breath was fetid. Soon the appetite failed and diarrhoea set in, which in a few days became mucous and bloody. On the inside of the cheeks and below the tongue phagedenic ulcers formed with a gray coating, and the teeth were attacked with caries. A high grade of anæmia followed, with emaciation, loss of appetite, and debility; the action of the heart grew feebler, and death took place in collapse. During the whole process the animals were very irritable and tremulous. Ne

paralysis was observed, but in some instances albuminuria. After death by *acute* poisoning the gastro-intestinal mucous membrane was hyperæmic and presented hæmorrhagic erosions, especially in the lower part of the small and in the large intestine, which also contained a bloody liquid. In some cases hæmorrhage had taken place in the heart-muscle and in the diaphragm, and there was hyperæmia of the mucous membrane of the cheeks and ecchymoses in the bladder. The liver and kidneys were congested, the blood dark and for the most part thick. In *chronic* poisoning there existed a high grade of gastro-intestinal catarrh, and oftentimes ulceration of the mucous membrane, but more frequently of the large than of the small intestine—in the former it was covered with diphtheritic exudation. Uniformly, ulcers of the cheeks and edges of the tongue existed, which were, however, rather wide than deep; the teeth were discolored and showed a tendency to caries. The liver and kidneys were hyperæmic. The experiments and observations of N. Popow (*Virchow's Archiv*, xciii. 351) prove that mercury, like arsenic and lead, tends to accumulate in the nervous system, and especially in the spinal marrow, where it gives rise to changes in the white as well as the gray central substance.

On Man: Metallic mercury has frequently been swallowed in quantities varying from several ounces to 2 pounds, generally for the purpose of overcoming an intestinal obstruction. Occasionally, but very rarely, it has salivated, and sometimes also by its bulk and weight it has ruptured a diseased bowel. It has been found repeatedly in the metallic form in the tissues of persons who had taken mercury or breathed an atmosphere impregnated with its fumes; and it has also been demonstrated in the secretions of the skin, the kidneys, and the mucous membranes, in the blood, milk, saliva, bile, and pus. It may be detected in the urine 8 weeks after the discontinuance of a constitutional course of mercury, and upon the skin after the use of a sulphurous bath. The absorption of mercury by the skin when mercurial ointment is applied by friction is no more an open question than the absorption of food and medicines by the stomach: the mode by which it is effected is not so evident. The present view is that metallic mercury, as soon as it comes into contact with the blood in the tissues to which it is applied, is changed into a soluble compound, which then is taken up to circulate through the system (*Fürbringer, Virchow's Archiv*, lxxxii. 491). The permanence of mercury in the system of those who have used the metal is shown by its having frequently been revived by the administration of iodide of potassium. Vajda and Pasekis, who studied this question thoroughly, have shown conclusively that in a large proportion (42 per cent.) of cases mercury may be found in the secretions of those who have been treated with it, and in one case fourteen years after the suspension of the treatment (*Phil. Med. Times*, x. 437). These results have been corroborated by Oberländer and by Schuster (*Amer. Jour. of Med. Sci.*, Oct. 1882, p. 574); but the latter could find no trace of the mineral in the feces after the lapse of a year. He thinks that little of it is excreted with the urine, and attributes the finding of it by others in the excretion to an erroneous interpretation of their experiments (*Zeitschrift f. klin. Med.*, vii. 80). Its absorption is illustrated on a large scale by the cachexia of the miners of and workers in mercury, and by the salivation and other specific effects produced on numbers of persons in an atmosphere accidentally contaminated by the emanations even of metallic mercury, and especially upon the inhabitants of districts near smelting-furnaces, among whom the proportion of abortions, stillbirths, and cachectic children is vastly in excess of that existing under other circumstances. All persons employed in trades which expose them to mercurial emanations, such as miners of mercury, gilders, mirror-makers, etc., are apt to be affected with a trembling palsy and other and fatal disorders of the nervous system.

The action of medicinal doses of the milder preparations of mercury (as blue mass and calomel) is first seen in an increase of the secretions, especially of the intestinal canal; but if the action be maintained, nutrition becomes impaired, as is shown by the tendency of newly-formed callus and other cicatricial matter to be absorbed, while the muscles waste, the skin grows pale, and œdema readily forms where the venous circulation is interrupted. These symptoms appear to denote an impaired crasis or a liquefaction of the blood, which, indeed, is further exhibited by a tendency to ecchymoses and to hæmorrhage. It would seem that, provided the dose of mercury be small, although large enough to cure syphilitic disease, its primary effect is not to diminish, but actually to increase, the proportion of the red corpuscles of the blood, no doubt by counteracting the morbid poison in that liquid. This was the conclusion of Keyes (*Amer. Jour. of Med. Sci.*, Jan. 1876, p. 17), who also inferred from his observations that mercury in small doses is a tonic (for a time at least) to individuals in fair health and not syphilitic, and in them increases the number of the red corpuscles. These general conclusions have been

confirmed by the experiments of Schlesinger (*Archiv f. exper. Pathol., etc.*, xiii. 317), who found that dogs and rabbits might continue for a year to take small doses of ammonio-chloride of mercury (*Quecksilber chloridechlorium*) not only without impoverishing the blood, but with a considerable increase of the red corpuscles. When at various periods the animals were sacrificed, no lesion whatever was found, but the deposit of fat was everywhere increased. Nevertheless, no evidence of a tonic influence of the mercury was perceptible, such as follows the use of iron, and especially no increase of the discharge of urea. Schlesinger is disposed to conclude, not that small doses of mercury improve nutrition, but that they limit waste—*i. e.* oxidation. On the whole, it would seem that mercury, like all active agents, medicinal or dietetic, exerts two opposite actions—the one when the dose is small, and the other when it is large and physiologically excessive. The power of mercury in the latter case to lessen the coagulability of the blood makes its use injudicious when there is already a hæmorrhagic tendency, and especially in females who suffer from repeated and profuse menorrhagia. (The existing state of knowledge respecting the action of mercury is set forth by Dr. E. B. Bronson in *Med. Record*, 1881, xx. 505.)

Along with the evidences of impaired nutrition just pointed out, another occurs which is peculiarly characteristic of the action of mercury. This is salivation. It is apt to be preceded and accompanied by feverishness and nervous susceptibility. The first local evidence of its occurrence is usually a metallic taste in the mouth, with soreness of the teeth when the jaws are struck together. The breath has a characteristic fetor. A red line may be observed first along the gingival attachments of the lower incisors, and then of the remaining teeth. The gums, lips, cheeks, tongue, and fauces are more or less tumefied, and the tongue has a sodden look, with an impression of the teeth upon its edges. The salivary glands are swollen and tender, and there flows from the mouth a transparent, viscid liquid of alkaline reaction and a penetrating smell. When salivation is excessive and prolonged, ulcers are apt to attack the gums, cheeks, and fauces, and in healing may cause the adhesion of contiguous parts; the breath becomes insufferably fetid, the teeth loosen and may fall out, and caries may attack the remaining teeth, and even the maxillary bones. Children and infants are seldom salivated, but when they are so the effects are apt to be very severe. Salivation is partly a reflex effect of the ulcerative processes in the mouth, and partly the sign of a direct action upon the salivary glands which they share with all the glands of the body.

Under the constitutional operation of mercury the appetite fails and the bowels readily become loose; it is probable that the pancreatic secretion is augmented, and very improbable that the secretion of bile is increased. The belief which was general and implicit that mercury had some mysterious control over the liver, through which it increased or diminished the secretion of that organ at the physician's will, has given place to a very general scepticism in regard to the matter; and, indeed, it is asserted that, compared with ipecacuanha, aloes, podophyllin, euonymin, ioidin, sanguinarin, rhubarb, colocynth, senna, coleicum, scammony, and certain sodium salts, mercury manifests the least degree of cholagogue operation. Upon the nervous system the action of mercury is depressing, occasioning a morbid susceptibility to cold and a state of mental uncertainty and restlessness, with feebleness of the intellectual powers. In some cases muscular spasm or paralysis, pain, or anæsthesia has been observed. It also appears to be injurious to the fœtus in utero and to favor miscarriage. Among its constitutional effects are cutaneous eruptions, generally in the form of eczema, sometimes in that of a febrile rubeoloid eruption, and more rarely as an eruption of bloody bullæ. Deep, foul, and intractable ulcers sometimes occur; they are most common within the cavity of the mouth and throat, and may prove fatal by hæmorrhage or by exhaustion, the ulcerative process sometimes destroying the cheeks and the soft parts of the throat. It appears probable that mercury may give rise to periosteal nodes which sometimes advance to the destruction of the bones. Finally, when administered too freely and for too long a period, mercury may produce a general cachexia, of which the chief phenomena are these: the muscles lose their firmness, and waste; the complexion turns pallid and earthy; the breath is fetid, and the urine readily becomes so; and usually there is diarrhœa. The gums grow spongy; the hair falls out; the bones and joints suffer dull pains; œdema of the ankles or general dropsy may supervene; hæmorrhage from the nose, bowels, kidneys, or reopened wounds takes place; and hectic fever, with tubercular consumption, may terminate life.

The effects of mercury upon the skin, which are referred to in the last paragraph, may well be illustrated by the following singular case: A healthy woman of nervous temperament after taking a mercurial pill was attacked with itching and burning of the skin,

which grew red and hot, and after some days began to desquamate in large flakes over the whole body. Two years afterward a similar cause produced analogous effects. Subsequently, she held in the hollow of her hand for a few moments a solution of corrosive sublimate, and, although the liquid was immediately thrown away and the hand thoroughly washed, within a week it became inflamed, cracked, and bleeding. On another occasion, having taken a bath at a boarding-house, and suffered in consequence with inflammation of the skin of the whole body, it was discovered that a lodger suffering from pediculi had also used the bath-tub after anointing herself with mercurial ointment (Watson).

To remedy, as far as possible, the mischiefs arising during a mercurial treatment, its use should be suspended in season, and attempts made by means of iodide of potassium, purgative mineral waters, and diaphoretics to hasten the elimination of the poison. The regimen should consist of nutritious food, protection from cold and dampness, and the cautious administration of iron. The local ulcerative lesions should be treated with washes of muriatic acid, chlorate of potassium, or nitrate of silver. A neglect of the regimenal, dietetic, and topical treatment of constitutional syphilis is responsible for many failures to cure the disease.

The mode of action of mercury, which may be inferred from the preceding summary of its effects, is the following: Being essentially non-nutritive, yet penetrating every tissue, it probably acts in small and transient doses as a stimulant of all organic processes, but in a little greater proportion and by continued use it impairs nutrition, hindering the formation of tissue on the one hand, and on the other hastening its destruction and elimination. At the same time it augments more or less the glandular secretions. It diminishes the proportion of fibrin, and, by its toxical action, the proportion also of the red corpuscles in the blood. Thus, hindering nutrition at every step of the latter action, mercury causes the waste of all the tissues, and especially of those least organized, as cicatrices and callus, and favors the removal of all plastic exudations. These effects are essentially morbid and destructive, and only incidentally and within varying limits can they become salutary.

Medical Uses.—It is probable that as much injury has been inflicted by the use of mercury in primary *syphilis* as good has been accomplished by its administration in the constitutional forms of the disease. And when it is considered that every simple sore following a suspected coition was apt to be treated as syphilitic by mercurialization of the system, it may be a question whether, on the whole, the medicine has not been more mischievous than useful. In regard even to true chancres, although mercurials will sometimes hasten their cure by lessening their induration, and may thereby postpone constitutional infection, it does not in any case prevent that result, nor even the enlargement of the inguinal glands. Moreover, in certain states of the primary sore and of the patient's system mercury aggravates the disease. Such is the case when the skin around the sore is very red, swollen, tense, and painful, or shows a tendency to gangrene—when the patient is anæmic, scrofulous, tuberculous, or scorbutic, or has been an habitual drunkard. Opinions differ in regard to treating pregnant syphilitic women with mercury; the better opinion is in favor of this measure for the sake of the child as well as the mother. But this judgment refers to secondary, not to primary syphilis.

Until comparatively recent times the treatment of constitutional syphilis consisted in the administration of mercury for the purpose of exciting profuse salivation, which was maintained for 4 or 5 weeks at a time. The disastrous consequences of this method, which had no other reason for its use than the hypothesis that the syphilitic poison was to be eliminated with the saliva, and which thus illustrated the folly and dangers of *a-priori* therapeutics, caused it at last to be abandoned, and it is now certain that mercury cures syphilis without salivation better than by means of it. The dose of mercury should at first always be small, and gradually increased until its effects on the disease begin to appear or some soreness of the gums occurs; it should then be continued in a diminished quantity, or even temporarily suspended if the symptoms begin to decline, but it should never be abandoned as long as any trace of the disease remains. This often involves a course of 6 months', or even of several years', duration; but it is safe, while the method of treatment with large doses of mercury is always hazardous. (Compare Gouguenheim, *Bull. et Mém. de la Soc. de thérap.*, 1883, p. 97.)

The treatment by inunction with mercurial ointment may be referred to here. It is one of the oldest modes of employing mercury in this disease, and is still a favorite hospital method, but it is too filthy for private practice, and it necessarily betrays the nature of the patient's disease. It, moreover, ruins all the body- and bed-clothing that

is used. The advantages attributed to it are that it is much less likely to disorder the bowels than mercury taken by the mouth; it cures, also, more quickly and with less risk of injuring the constitution. It is chiefly appropriate to the treatment of syphilitic affections of the skin, and, next to these, but far less efficiently, to ulcerated states of the mouth and throat, and still less to syphilitic disorders of the nervous system. Syphilis of the bones and their annexes is more successfully treated with iodide of potassium. Before commencing mercurial inunction the patient should live for some days on simple food, use laxative medicine, and cleanse the skin thoroughly by warm bathing. Immediately afterward, in bed or near a warm fire in winter, the ointment should be methodically rubbed into the skin with the hand protected by a caoutchouc glove or a piece of softened pig's bladder. The places selected for friction should be used alternately or in succession, as the thighs, the armpits, the legs, the arms, etc., and if the part is hairy it should be shaven and the frictions made in the direction of the hairs. About 2 drachms (Gm. 8) should be rubbed in daily for 5 or 6 days, at the end of which time the patient should have a warm bath with soap and be allowed to quit his bed, but warmly clothed. After an interval of a week the same discipline should be renewed, and this generally suffices for a cure. The result is supposed to be quickened by the use of sudorific diet-drinks, such as the compound decoction of sarsaparilla. Mercurial inunction of syphilitic infants is conveniently performed by enveloping the trunk of the patient with a flannel band that has been smeared with mercurial ointment. The use of other mercurial compounds in syphilis is treated of in connection with the several preparations of the medicine, and also the hypodermic use of mercurial salts, which possesses all the advantages, with none of the special disadvantages, belonging to the method by inunction (*Centralblatt f. Ther.*, i. 355). Mercurial soap has been used in place of mercurial ointment, and with alleged success. It has a great advantage over the ointment in cleanliness (*Oberländer, Centralbl. f. Ther.*, i. 150).

In the greater number of *febrile* and *inflammatory* affections calomel is the form of mercury usually selected by those who believe mercurials appropriate to these diseases, but sometimes its action is supplemented by the use of mercurial ointment, as in acute *meningitis*, *pericarditis*, *hepatitis*, etc. In these cases it is generally applied upon a blistered surface. In *acute dyspepsia*, often accompanied with jaundice and produced by excesses in eating and drinking and a constipated habit, a superstitious belief prevails among English physicians and their American copyists that the sovereign and specific remedy is blue pill, followed by a saline cathartic. Other nations, it is true, relieve such symptoms by the saline alone or by rhubarb and aloes along with it. Whenever congestion of the liver is associated with enlargement of the spleen, the administration of blue pill or other mercurial is extremely apt to be followed by profuse salivation, and even by gangrene of the mouth. An apparent exception to this rule is the cure of malarial enlargement of the *spleen* by the external use of biniodide of mercury. Metallic mercury has been used to overcome *intestinal obstructions* supposed to be formed by invagination, and also to expel intestinal worms. A case of the former sort in which the expedient was successful occurred in 1879 (*Med. Record*, xvii. 121). Bettelheim has reported seventy cases "of intestinal stenosis, of which fifty-seven were relieved" by this expedient alone, and in six it saved the lives of the patients (*Phila. Med. Times*, xiv. 174). Mercurial ointment is probably the best remedy for *ascarides of the rectum*. It is generally used as an application around the eye in the treatment of acute *iritis*, along with the internal use of calomel. It is a valuable auxiliary also in the treatment of true *croup* (pseudo-membranous laryngitis), when it should, from the commencement of the attack, but only in primary and sthenic cases, be rubbed into the axillæ and the groins. It is of all medicines the least to be advised in *diphtheria*, which is always an asthenic disease. And yet that it has been so is shown by the sharp and well-merited criticism of Jacobi, who says, "That it should be recommended as a panacea in all classes and forms of diphtheria shows that common sense and sound judgment do not always prevail in the treatment of a disease where individualizing is of the utmost importance" (*A Treatise on Diphtheria*, p. 188). The source of this deplorable error is in confounding epidemic diphtheria with true membranous croup. Mercurial ointment relieves the pain and is said to subdue the inflammation in *paronychia*; it has an analogous effect in *erysipelas*; and there is reason to believe that it checks the development of *small-pox* pustules, and thereby tends to prevent their pitting. Metallic mercury has been successfully used to amalgamate with a *gold ring* which had become too tight for the finger, and to render it so brittle that it readily broke under pressure. The ring in such cases should first be cleansed with alcohol or ether.

Metallic mercury is seldom given internally, except as above mentioned and in the modified form of blue pill. (See PIL. HYDRARGYRI.)

HYDRARGYRUM AMMONIATUM, U. S., Br.—AMMONIATED MERCURY.

Hydrargyrum præcipitatum album, P. G.; *Hydrargyrum amidato-bichloratum* (ammonio-muriaticum), *Hydrargyri ammonio-chloridum*, *Mercurius præcipitatus albus*.—White precipitate, *Mercur-ammonium chloride*, E.; *Chloramidure de mercure*, *Oxychlorure ammoniacal de mercure*, *Lait mercuriel*, *Mercurie précipité blanc*, Fr.; *Weisser Quecksilberpräcipitat*, *Quecksilber-Chloridamidid*, G.

Formula NH_2HgCl . Molecular weight 251.1.

Preparation.—Corrosive Chloride of Mercury 10 parts (5 oz. av.); Water of Ammonia, Distilled Water, each a sufficient quantity. Dissolve the corrosive chloride of mercury in 200 parts (100 oz. av. or 6 pints) of warm distilled water; filter the solution, and allow it to cool. Pour the filtrate gradually, and constantly stirring, into 15 parts ($7\frac{1}{2}$ oz. av. or $7\frac{1}{2}$ fluidounces) of water of ammonia, taking care that the latter shall remain in slight excess. Collect the precipitate upon a filter, and when the liquid has drained from it as much as possible wash it twice with a mixture of 20 parts (10 oz. av. or $9\frac{1}{2}$ fluidounces) of distilled water and 1 part ($\frac{1}{2}$ oz. av. or $\frac{1}{2}$ fluidounce) of water of ammonia. Finally, dry the precipitate between sheets of bibulous paper in a dark place, at a temperature not exceeding 30°C . (86°F).—U. S.

The process of the German Pharmacopœia is in all respects identical with the foregoing, except that the washing of the precipitate is accomplished with distilled water instead of diluted ammonia. The process of the British Pharmacopœia is like the last, but a somewhat smaller quantity of ammonia is directed, and the precipitate is dried at a temperature not exceeding 100°C . (212°F). The French Codex no longer recognizes this preparation; it should, however, be remembered that the *précipité blanc* of French pharmacy is *calomel* prepared by precipitation (see page 775).

In following the above processes one-half of the ammonium has 2 atoms of the univalent hydrogen replaced by 1 atom of the bivalent mercury, producing the radical mercur-ammonium (NH_2Hg), which is a monad like ammonium, and combines with 1 atom of chlorine to form the white precipitate; the other half of the ammonium unites with the other atom of chlorine contained in the mercuric chloride to form ammonium chloride, which remains dissolved; water is likewise produced by the reaction, which is explained by the equation $\text{HgCl}_2 + 2\text{NH}_4\text{HO} = \text{NH}_2\text{HgCl} + \text{NH}_4\text{Cl} + 2\text{H}_2\text{O}$. The ammonium chloride requires to be washed out, for which purpose the Pharmacopœia very properly uses a very dilute ammonia to prevent decomposition. If water be used, it should be cold, and the washing should not be continued too long, to prevent the precipitate from acquiring a yellowish tint in consequence of the formation of oxidi-mercur-ammonium chloride, $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$. The above formula yields $9\frac{1}{4}$ parts ($4\frac{3}{4}$ oz.) of ammoniated mercury.

Properties.—Ammoniated mercury is a white, amorphous, inodorous powder or is often in friable masses, permanent in the air and having an earthy afterward metallic taste; the U. S. P. describes it as tasteless. It is insoluble in ether, alcohol, and ammonia-water, but is slowly decomposed by cold water, and yields with boiling water a lemon-yellow basic compound, $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$, ammonium chloride being dissolved. When rapidly heated it turns yellow, and above 360°C . (680°F .) is decomposed and completely volatilized without fusion, yielding nitrogen, ammonia, and calomel; when slowly heated intermediate compounds are first formed. It is completely soluble in a cold solution of hyposulphite of sodium, with evolution of ammonia; on digesting this solution for a short time it separates red mercuric sulphide, or vermilion, which on protracted boiling turns black. Ammoniated mercury is decomposed by potassa solution or lime-water, ammonia being evolved and a yellow compound separated. It is soluble in hot solutions of ammonium salts and in hydrochloric as well as in nitric and acetic acids; these solutions yield white precipitates with potassa (ammoniated mercury) and silver nitrate (silver chloride). When ammoniated mercury is triturated with iodine the mixture will after some time puff up, from the spontaneous decomposition of iodide of nitrogen or iodamine formed in it, but in the presence of alcohol the decomposition takes place suddenly and with violent explosion.

Tests.—Ammoniated mercury should dissolve in hydrochloric acid without effervescence (absence of carbonate), and without leaving any residue (absence of mercurous

salt, calcium sulphate, starch, etc.). Its solution in acetic acid should not yield a precipitate with sulphuric acid (absence of lead), and, after treating it with an excess of hydrogen sulphide a colorless filtrate should be obtained, which, on being acidulated with hydrochloric acid, evaporated to dryness, and ignited, should not leave a fixed residue (absence of zinc, calcium, etc. salts).

FUSIBLE WHITE PRECIPITATE, which was formerly considered to be identical with the preceding, until Wöhler and Kane proved its difference, was prepared by dissolving ammonium and mercuric chlorides in water and precipitating with sodium carbonate. Thus obtained, it has the composition $(\text{NH}_4)_2\text{HgCl}_2$, or perhaps $\text{NH}_4\text{Cl}.\text{NH}_2\text{HgCl}$, and differs from the official ammoniated mercury in fusing, when heated, to a yellowish liquid, evolving nitrogen and ammonia and yielding a transparent and an opaque white sublimate.

Off. Prep.—Unguentum hydrargyri ammoniati, *U. S., Br.*

Medical Action and Uses.—The insolubility of ammoniated mercury in water, and even in the normal acid contents of the stomach, renders it a less active irritant than some other mercurial salts. Sometimes its harsh operation seems to be attributable to defects in its manufacture or to its exposure to light, whereby a portion of it is converted into corrosive sublimate. Certainly in several cases it has occasioned all the symptoms of an active poison, with the specific effects of mercury, and a fatal result at last. The following case illustrates its action: A man aged forty took about 40 grains of white precipitate. He had suffered from vomiting and purging during some 12 hours, and when seen his mouth and throat were sore, his pulse feeble and frequent, and his skin cool and clammy. The lower lip was blistered at the corners, as were also the swollen tongue and the pharynx. The belly was tympanitic and tender upon pressure. In the vomit were found some shreds of mucous membrane, and the stools were bloody and mucous. Two days later general tremor existed, which continued until salivation was established. The latter lasted nearly a fortnight, and was accompanied by some sloughing of the lower lip and gums and loosening of the teeth. The patient recovered (*Times and Gaz.*, March, 1882, p. 302). This preparation is not used internally as a medicine, but its ointment, which is official, is employed in *ophthalmia* and *skin diseases*.

HYDRARGYRUM CUM CRETA, *U. S., Br.*—MERCURY WITH CHALK.

Æthiops cretaceus.—Mercure avec la craie, Poudre de mercure crayeux, *Fr.*; Quecksilber mit Kreide, *G.*

Preparation.—Mercury 38 parts (380 grains); Sugar of Milk, in fine powder, 12 parts (120 grains); Prepared Chalk 50 parts (500 grains); Ether, Alcohol, each a sufficient quantity; to make 100 parts (1000 grains). Mix the mercury, sugar of milk, and 12 parts (120 grains) of the chalk in a suitable mortar; moisten the mass with a mixture of equal parts of ether and alcohol, and triturate it briskly. Gradually add the remainder of the chalk, dampen the powder occasionally with a mixture of ether and alcohol made in the same proportions as before, and continue the trituration until globules of mercury are no longer visible under a magnifying power of 10 diameters and the powder is of a uniform gray color, and dry.—*U. S.*

Take of mercury, by weight, 1 ounce; prepared chalk 2 ounces. Rub the mercury and chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye and the mixture acquires a uniform gray color.—*Br.*

When certain substances are triturated with metallic mercury they acquire a gray tint, and the metallic lustre of the mercury gradually disappears in consequence of its fine division. (See HYDRARGYRUM.) To effect this with chalk alone is a tedious operation, to shorten which Dr. Stewart (1843) proposed to triturate first with resin, then with chalk, and finally to remove the resin by alcohol; Dr. Mettner suggested the use of a mixture of starch and chalk, kept damp by a little water during the trituration; and W. Hewson (1850) proposed to shake the metal with a portion of the chalk in a bottle until extinguished, and then to add the remaining powder. This process is followed on a large scale, a barrel or other suitable vessel containing the mixture being turned on its axis, or it is combined with trituration, a ball being also introduced into a vessel having a somewhat eccentric motion. Dr. Squibb (1857) constructed an apparatus in which the mercury is shaken with honey or syrup, and when completely extinguished mixed with the chalk, most of the sugar being afterward washed out with cold water; this process yields a very pure product, but the globules are larger than in the products of the other processes, and the powder cannot be triturated with pressure without separating some metallic globules.

W. E. Bibby (1876) suggested a method which enables the pharmacist to prepare this medicament without the expenditure of much time by substituting sugar of milk for about one-fifth of the chalk, which greatly facilitates the fine division of the metal; this is the process adopted by the U. S. P., with the additional improvement to keep the material moist with alcohol and ether until the mercury has been finely divided.

Properties and Tests.—Mercury with chalk is a gray, uniform, non-gritty, inodorous, and nearly tasteless powder, from which the mercury may be volatilized by heat. When treated with an excess of diluted acetic acid the chalk dissolves with effervescence, metallic mercury being left behind; the solution thus obtained usually yields a faint turbidity on the addition of hydrochloric acid, calomel being formed with the *mercurous oxide* dissolved by the acid. The presence of this oxide is disregarded by the British Pharmacopœia, which requires the preparation to be partly dissolved by dilute hydrochloric acid; any mercurous oxide present would be converted into calomel and remain with the finely-divided, undissolved mercury; but it insists on the total absence of *mercuric oxide*, which is detected in the clear solution in hydrochloric acid by a white or gray precipitate with stannous chloride or by a black one with hydrogen sulphide. Arsenic may be detected in this solution in the same manner as in corrosive sublimate (see page 771). Dr. Squibb (1857) determined in a sample the presence of 1.2 per cent. of mercurous and 1.44 per cent. of mercuric oxide; Joseph P. Remington (1869) found even 14.3 and 25.7 per cent. of the latter in two samples taken from dispensing-bottles. These results fully explain the violent action which has been occasionally observed. The preparation should be examined from time to time to ensure its fitness for medicinal use, notwithstanding the U. S. P. has omitted to give tests for determining its quality.

Medical Action and Uses.—This preparation seems to be only metallic mercury maintained in a state of minute subdivision by chalk. The proportion of the latter ingredient is too small to be regarded as of any direct therapeutic value, for in 8 grains of the compound there are 3 of mercury and 5 of chalk; and in the dose of 2 or 3 grains, in which it is generally administered, any immediate action except that which belongs to an unirritating insoluble powder can scarcely be admitted. Mercury with chalk is chiefly used in the *bowel complaints* of children, especially when the discharges are colorless and sour, and is very generally believed to cause a secretion of bile, and thus restore the normal action of the alimentary canal. Of this action, as elsewhere stated (see HYDRARGYRUM), no proof exists. The chief good it does is very probably to take the place of larger doses of more perturbative medicines. *Dose*, from 3 to 10 grains (Gm. 0.15–0.50).

HYDRASTIS, U. S.—HYDRASTIS.

Golden seal, Yellow-root, Yellow puccoon, Orange-root, Indian dye, Indian turmeric, E.; Racine d'hydrastis de Canada, Secau d'or, Fr.; Canadische Gilbwurzel, G.

The rhizome, with the rootlets, of *Hydrastis canadensis*, Linné, s. *Warnera canadensis*, Miller. Bentley and Trimen, *Med. Plants*, 1.

Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—This perennial is indigenous to Canada and the United States east of the Mississippi; it grows in rich woodlands, and in the Southern States is confined to the mountainous districts. It has a low stem, and at the summit two round heart-shaped, palmately-lobed leaves and a single greenish-white flower, and produces a crimson fruit composed of twelve or more one- or two-seeded berries.

Description.—The rhizome is 1 to 2 inches (2 to 5 Cm.) long, about $\frac{1}{4}$ inch (6 Mm.) thick, oblique, with several short branches, terminated by a broad concave scar, somewhat flattened, annulate from the leaf-scars, longitudinally wrinkled, and below beset with many thin fragile rootlets 3 to 5 inches (75–125 Mm.) long, containing a thin triangular or quadrangular ligneous cord and a thick bright-yellow bark. The rhizome is externally brownish-gray with a yellow hue, hard, and breaks with a short waxy fracture of a bright reddish- or brownish-yellow color; the bark is about one-eighth the thickness of the rhizome; the central pith and medullary rays are broad, and the yellowish wood consists of eight to twelve narrow wedges, or, near the base of the branches, of a few linear and several larger irregular bundles. Golden seal has a slight odor, and a bitter taste free from any marked astringency.

FIG. 152.

Hydrastis.

Constituents.—Besides the common constituents, like starch, sugar, etc., A. B. Durand (1851) found in it a yellow coloring matter and a white alkaloid, *hydrastine*. The former was recognized by Mahla (1862) as *berberine*, the hydrochlorate of which has been used by eclectic practitioners under the incorrect name of *hydrastine*. Perrins (1862) obtained 4 per cent. of the crude hydrochlorate (see BERBERIS, p. 315) and 1.5 per cent. of hydrastine, which was analyzed by Mahla (1863). *Hydrastine*, $C_{22}H_{23}O_6$, is contained in the mother-liquor from the preparation of berberine, and obtained by diluting the liquid with water, evaporating the alcohol, neutralizing carefully with ammonia, filtering from the precipitated resin, etc., and precipitating with ammonia; the fawn-colored deposit is purified by animal charcoal and recrystallization from hot alcohol. It is in white, shining quadrangular prisms which fuse at 135° C. (275° F.), are readily soluble in alcohol, ether, chloroform, and benzol, insoluble in water, colored red by nitric acid, brown-red by sulphuric acid and potassium chromate, and yield with acids soluble and very bitter salts. From the investigations of A. K. Hale (1873) and J. C. Burt (1875), it appears that the hydrastine of former investigators was not quite pure, but probably mixed with a third alkaloid, which Hale obtained of a dark-yellow color, and Burt crystallized as sulphate in colorless needles; warmed with nitric acid, it turns red, with sulphuric acid reddish-brown, and the solution of its hydrochlorate is colored dark-brown to black by ferric chloride; it is present in smaller quantity than hydrastine. Lerchen (1878), who proposed to call it *xanthopuccine*, found it insoluble in ether and chloroform, but soluble in alcohol and hot water, and the hot alcoholic solution, treated with iodine in potassium iodide, avoiding an excess of iodine, to yield light brown-colored spangles. In the preparation of the alkaloids Dr. L. Wolff (1881) has found it of considerable advantage to deprive the powdered hydrastis of the fixed oil by means of gasoline, and thus lessen the trouble of purification.

Off. Prep.—Extractum hydrastis fluidum, Tinctura hydrastis, U. S.

Medical Action and Uses.—The bitter taste of this root probably led to its employment as a stomachic tonic and in mild cases of intermittent fever. A variety of incongruous virtues have been attributed to it by the ignorant, such as being at once tonic, aperient, diuretic, and antiseptic. So far as its active principles have been tested, they display no peculiar virtues. Besides being used in constipation, hæmorrhoids, jaundice, and chronic diarrhœa, it has been vaunted as a remedy for all diseases of the urinary tract and in leucorrhœa, as well as for ophthalmia and cancer. According to Schatz, it induces contraction of the blood-vessels of mucous membranes and diminishes congestion of the genital organs (*Centraltbl. f. d. g. Therapie*, ii. 82). From his experiments on the dog with the resinous extract known as “hydrastine,” Rutherford concluded it to be an “hepatic stimulant of considerable power and a feeble intestinal stimulant.” We are assured that hydrastis “is a stomachic tonic, one of the best remedies for the gastric catarrh of chronic alcoholism, and probably the best substitute for alcoholic stimulants when their use has to be abandoned. For habitual constipation depending on inaction of the liver it is undoubtedly a valuable remedy” (*Practitioner*, xxvi. 121). That a medicine should be alleged to be the best substitute for alcoholic drinks and also a remedy for habitual constipation, and all that it is said to be besides, implies marvellous virtues in it, or still more marvellous faith in those who make such an assertion. To this already long list of its virtues may be added the more recent statement of its efficacy in *uterine hæmorrhage*, especially when due to *myomata*. 20 or 30 drops of a tincture are given at short intervals until the bleeding is controlled, after which doses of from 2 to 5 drops are directed at longer intervals. It is also claimed to be serviceable in *dysmenorrhœa* depending upon chronic endometritis when taken in doses of from 7 to 10 drops of the tincture. Although it is expressly stated to be free from any marked astringency, it is especially recommended for the treatment of prolapse of the *rectum* in children, in fissure of the *anus*, and in ulceration of the rectal mucous membrane. In *gonorrhœa* a solution of 60 grains of hydrastine (the alkaloid) in 4 ounces of mucilage of acacia has been recommended as an injection, and also 2 drachms of the tincture to a pint of water. “In *fissure of the nipples* hydrastine has been strongly recommended, and it is said to be a good application in *stomatitis*, *otorrhœa*, *ozæna*, *conjunctivitis*, *leucorrhœa*, etc.” To this list is added “cancer.” In other words, it seems to have been found useful in affections for which are also employed baptisia, heuchora, salvia, ceanothus, etc. The statements thus briefly summarized render it probable that hydrastis is worthy of a serious and intelligent investigation. A decoction is made by boiling an ounce (℥m. 32) of the bruised rhizome in a pint of water for 15 minutes. Of this 1 or 2 fluidounces may be taken several times a day. The fluid extract is the most convenient form for administration.

HYDROCOTYLE.—WATER-PENNYWORT.

Indian pennywort, E.; *Bevilacqua*, Fr.; *Wassernabel*, G.

Hydrocotyle asiatica, *Linné*. Bentley and Trimen, *Med. Plants*, 117.

Nat. Ord.—Umbelliferae, Orthospermæ.

Description.—A low, creeping perennial which is indigenous to the tropical and subtropical regions of Asia, Africa, and America. The leaves are smooth, situated in tufts on the nodes of the stem, have petioles with a sheathing base, are roundish-reniform in outline with a somewhat crenate margin, about an inch (25 Mm.) broad, rather thick, radiately veined, and dark-green. The pink-colored flowers are in small umbellate clusters of about three, and produce small, laterally flattened, suborbicular fruits without oil-tubes. The plant is inodorous, but in bruising the fresh leaves a peculiar odor is developed; the taste is bitterish and pungent.

Constituents.—Lépine (1855) isolated *vellarin*, which he regarded as the active principle. It is an oily liquid having a bitter taste, a strong, peculiar odor, becoming viscous on exposure, insoluble in potassa solution, and soluble in ammonia, diluted alcohol, and ether. He obtained from the dried leaves 13 per cent. of ash.

Allied Plants.—Most other species of this genus appear to possess somewhat similar sensible properties. The North American species, *H. ramunculoides*, *Linné*, and *H. americana*, *Linné*, have likewise reniform leaves, those of the former being three- to seven-cleft; those of the latter, thin, crenate-lobed, the lobes of both being crenate.

Peltate leaves, with doubly crenate margins, are met with in the European *H. vulgaris*, *Linné*, which has five-flowered umbellate clusters, and in the American *H. umbellata*, *Linné*, which has the umbellate clusters about twenty-flowered.

Medical Uses.—About 1852 this medicine, which had long been employed in India in the treatment of febrile diseases and as a diuretic, was announced by a French physician in the Mauritius to have cured a case of *leprosy*. Other reports of a favorable character proceeded from different quarters, some of them containing specific details of the cure of this fatal affection in numerous instances, and then it fell into complete disfavor, as other medicines of like pretensions had done. Meanwhile, it was said to be an efficient remedy in scaly and pruriginous diseases of the skin, including those of a syphilitic origin, in chronic *eczema*, *lichen*, *prurigo*, in scrofulous and other *ulcers*, and in chronic *rheumatism*. The powdered root has been prescribed in doses of 3 grains (Gm. 0.20) several times a day, and an alcoholic extract in doses of $\frac{1}{2}$ grain (Gm. 0.03).

HYDROGENII PEROXIDUM.—PEROXIDE OF HYDROGEN.

Hydrogen dioxide, E.; *Peroxide d'hydrogène*, Fr.; *Wasserstoffhyperoxyd*, G.

Formula H_2O_2 . Molecular weight 34.

Origin.—Thénard (1818) discovered this compound, which has also been called *oxygenated water* and *oxygen hydrate*, by acting with dilute acids upon peroxide of barium. Meissner (1863) proved its presence in the rain-water collected during thunder-storms, and this observation has since been corroborated by Schönbein (1869), Struve, and others. Houzeau (1868) did not succeed in finding it.

Preparation.—The preparation of a solution of peroxide of hydrogen depends upon the decomposition of barium peroxide (see page 299) by hydrochloric acid in the presence of ice-cold water, and the precipitation of the newly-formed barium chloride by means of sulphate of silver. Instead of hydrochloric, carbonic or hydrofluoric acid may be employed, or peroxide of potassium may be acted upon by hydrofluosilicic acid. Such solutions usually contain about 3 to 5 per cent. of the peroxide, and are concentrated by freezing, the last portions of water being evaporated *in vacuo* over sulphuric acid at a temperature not exceeding 20° C. (68° F.).

Properties.—Thus prepared, peroxide of hydrogen forms a colorless, transparent, syrupy liquid, which has the spec. grav. 1.452, does not congeal at -30° C. (-22° F.), and volatilizes *in vacuo*, slowly and without decomposition, at the ordinary temperature. But when exposed to the sunlight or when heated, or brought into contact with charcoal, silver, gold, the platinum metals, the oxides of manganese, alkalies, or various other compounds, the peroxide is decomposed, often with explosive violence, and in the presence of the oxides of the metals mentioned these are reduced to the metallic state. Some other bodies act less energetically or are oxidized. Litmus- and turmeric-paper are gradually bleached. Peroxide of hydrogen is without odor and has a harsh and bitter taste; applied to the skin, it colors it white and produces violent itching. It is soluble in water

in all proportions, which solutions are decomposed by the same agents as the pure compound, but less violently, and are rendered somewhat more permanent by the addition of a small quantity of a mineral acid. Exposed to a low temperature, water freezes, and a stronger solution of peroxide is left.

Composition.—Peroxide of hydrogen is regarded by Traube as H_2O_2 , or a compound of an oxygen molecule with 2 atoms of hydrogen. Viewed as the *binoxide* or *dioxide of hydrogen*, its formula is H_2O_2 , and viewed as a hydrate of oxygen, $\text{O.H}_2\text{O}$. The oxygen, which is given off under the conditions mentioned above, has been regarded by Schönbein and others as a peculiar modification which has been called *positive oxygen* or *antiozone*, to distinguish it from *ozone*, or oxygen in the negative condition. The correctness of these distinctions, however, is denied by many investigators.

Solutions.—*Aqueous solution of hydrogen peroxide*, containing 3 per cent. of the latter, is now prepared on a large scale for the purpose of bleaching animal products, like feathers, hair, silk, bone, etc. The solution should be free from acids, and keeps well, provided the light be excluded and the temperature does not rise above 25°C . (77°F). It is known as ten-volume peroxide of hydrogen, it yielding about 10 volumes of active oxygen, which may be estimated by adding a sufficient amount of sulphuric acid, and afterward a standardized solution of potassium permanganate, as long as the latter is decolorized, the reaction taking place according to the equation: $5\text{H}_2\text{O}_2 + 2\text{KMnO}_4 + 3\text{H}_2\text{SO}_4 = 8\text{H}_2\text{O} + 5\text{O}_2 + 2\text{MnSO}_4 + \text{K}_2\text{SO}_4$.

Ethereal solution of hydrogen peroxide has been prepared by Böttger by adding impure sodium peroxide (obtained by the burning of sodium) to a cold mixture of 1 part of sulphuric acid and 24 parts of water, with the precaution of avoiding an elevation of temperature; the mixture is then repeatedly agitated with ether. Such a solution was used by Dr. Richardson (1869) under the name of *ozone ether*. He found that the addition of a little alcohol to the ether facilitates the absorption of the peroxide, and that the combination of the latter with the ether and some water, although very slight, is persistent, for the mixture was sent to Australia without deterioration.

Physiological Action.—Experiments made on animals by Guttman and by Schwerin furnished the following results (*Virchow's Archiv*, lxxiii. 23, 37): 4 Ccm. of peroxide of hydrogen injected under a rabbit's skin immediately caused severe dyspnea, clonic convulsions, and death in a few minutes from asphyxia. An examination showed the right auricle and ventricle filled with a frothy blood. Microscopic examination of the pulmonary circulation in curarized hogs injected with the peroxide showed that the bubbles of oxygen never penetrated the branches of the pulmonary artery. Guttman found that if $\frac{3}{4}$ Ccm. of the peroxide solution is injected into one side of a rabbit's abdomen, and twice that quantity of a 20 per cent. solution of ferrous sulphate is simultaneously injected into the other side, the animal will not die, although $\frac{3}{4}$ Ccm. is the lowest fatal dose. Hence he concludes that at least a part of the oxygen liberated from the peroxide combines with the sulphate, and that the remainder is insufficient to obstruct the circulation and cause asphyxia. Peroxide of hydrogen is powerfully antiseptic, although, according to some authorities, it is less so than carbolic acid.

Medical Uses.—Upon theoretical grounds this compound was introduced as a cure for *diabetes*, but it signally failed after a sufficient trial by competent judges. It would seem to have had a favorable influence on some forms of atonic *dyspepsia*. It was also supposed to act as a palliative in various cases of *dyspnea* due to an impeded circulation of blood through the heart and lungs. It is unnecessary to enumerate the other diseases in which it proved to be valueless as an internal remedy. Externally, it has been applied to *ulcers* of various kinds. It seems to promote their healing, both by stimulating them and coagulating their secretions, and in the case of *syphilitic sores* it is thought to disinfect their virus. It has been used in an ointment (1 part to 7 of lard) to anoint the skin of *scarlet-fever* patients, with the alleged result of diminishing the mortality and preventing the spread of the disease. There is no sufficient ground for this opinion. Peroxide of hydrogen may be given in tablespoonful doses of a solution of 1 part of the peroxide in 20 of water.

In 1878, Day claimed that the numerous hydrocarbons used in dressing wounds, etc., owed their utility to their faculty of absorbing oxygen and giving it up to the tissues, and hence that the aqueous solution of peroxide of hydrogen, or any of the above substances capable of generating it, must prove valuable as a surgical dressing (*Times and Gaz.*, Aug. 1878, p. 193). (Goolden also, and others, testified to the powers of the gas to limit ulceration (*Practitioner*, xxiv. 47). And in 1882, Péan and Baldy drew the following conclusions from their clinical experience: Water containing from two to six times

its volume of oxygen appears to be a fit substitute for alcohol and carbolic acid. It can be used as a dressing for every sort of wound and ulcer by injection and in vapor; in some cases, partly surgical, it may be given internally. It greatly hastens the cicatrization of fresh or of old wounds, even when covered with gangrene. It lessens traumatic fever; it neither offends by its smell nor acts poisonously, as carbolic acid does; and it occasions no pain. It seems adapted to ulcers of every description, deep abscesses, ozena, and purulent cystitis. And, finally, it destroys microbes (*Bull. de thérap.*, ciii. 122).

HYOSCYAMINÆ SULPHAS, U. S.—SULPHATE OF HYOSCYAMINE.

Hyoscyaminum sulfuricum.—*Sulfate d'hyoscyamine*, Fr.; *Hyoscyaminsulfat*, G.

Formula $(C_{17}H_{23}NO_3)_2 \cdot H_2SO_4$. Molecular weight 676.

The neutral sulphate of an alkaloid prepared from hyoscyamus.

Preparation.—Hyoscyamine is dissolved in alcohol, and the solution carefully neutralized with diluted sulphuric acid and evaporated at a low temperature; or, the solution of the alkaloid in diluted sulphuric acid is concentrated under a bell-glass over sulphuric acid.

Properties.—Hyoscyamine sulphate is described by E. Rennard (1868) as forming bundles of microscopic crystals; by Thorey (1869), as crystallizing in long satiny prisms, united in bundles or sheaf-like groups; and by Höhn and Reichardt (1871), as radiating groups of white glossy needles, which lose at 70° C. (158° F.) 5.19 per cent. and at 110° C. (230° F.) 9.3 per cent., of water, the latter amount indicating $4H_2O$ (9.76 per cent.). But, according to Ladenburg (*Annalen*, vol. cevi.), the salts of hyoscyamine are uncrystallizable, while those of hyoscyne, or amorphous hyoscyamine, are crystallizable; most of the salts of both alkaloids are colorless or white if pure, but as ordinarily obtained are usually more or less colored (see HYOSCYAMUS); and no method is known for separating the two alkaloids except by the recrystallization of their gold double salts. It is evident, therefore, that the pharmacopœial description of hyoscyamine sulphate applies to a mixture with hyoscyne sulphate more or less contaminated with coloring matter: "Small golden-yellow or yellowish-white scales or crystals, or a yellowish-white amorphous powder, deliquescent on exposure to air, odorless, having a bitter and acrid taste and a neutral reaction. Very soluble in water and in alcohol. When heated on platinum-foil the salt chars, and is finally completely dissipated. An aqueous solution of the salt is not precipitated by test solution of platinic chloride. With chloride of gold it yields a precipitate which, when recrystallized from boiling water acidulated with hydrochloric acid, is deposited on cooling (without rendering the liquid turbid) in brilliant, lustrous, golden-yellow scales (difference from atropine). The aqueous solution yields, with test solution of chloride of barium, a white precipitate insoluble in hydrochloric acid."—U. S.

Action and Uses.—These are detailed in the following article on HYOSCYAMUS. The dose of the sulphate is about the same as that of the alkaloid, hyoscyamine, $\frac{1}{15}$ grain (Gm. 0.001); but in urgent cases $\frac{1}{4}$ grain, and even a grain (Gm. 0.016–0.06), has been given by the mouth, and $\frac{1}{65}$ grain (Gm. 0.001) hypodermically.

HYOSCYAMUS, U. S.—HYOSCYAMUS.

Hyoscyami folia, Br.; *Herba hyoscyami*, P. G.—*Hyoscyamus-leaves*, *Henbane-leaves*, E.; *Feuilles de jusquiame noir*, Fr.; *Bilsenkraut*, G.

The leaves of *Hyoscyamus niger*, *Linne*, collected from plants of the second year's growth. Steph. and Church, *Med. Bot.*, plate 9; Bentley and Trimen, *Med. Plants*, 194.

Nat. Ord.—Solanaceæ.

Origin.—The typical form of henbane is biennial, grows in sandy soil and waste places throughout the greater portion of Europe and eastward and southward to Siberia, Northern India, and Egypt, and has been naturalized in North America from the New England States to Michigan. It is 2 to 3 feet (60–90 Cm.) high, covered with long, jointed, glandular hairs, and has the numerous nearly sessile flowers in a long, leafy, one-sided spike-like raceme. The funnel-shaped five-lobed corolla is about 1½ inches (3 Cm.) long and wide, pale yellow, with purple veins and a similar colored base. The capsule (pyxis) is enclosed in the bell-shaped calyx, about ¼ inch (12 Mm.) long, dehiscent near the top by a cap, two-celled, and contains numerous seeds. An annual variety, *H. agrestis*, *Kittibab*, is not over a foot (30 Cm.) high, less villous, and has smaller leaves and fewer flowers; if the latter are veinless, the plant is *H. pallidus*, *Willdenow*.

H. albus, *Linné*, and *H. aureus*, *Linné*, of Southern Europe, are occasionally employed there, but are less active. *H. physaloides*, *Linné*, is used in Siberia.

Description.—Taken from different parts of the stem, the leaves vary from 2 to 10

FIG. 153.

*Hyoscyamus niger*, *Linné*.

inches (5–25 Cm.) in length and 1 to 4 inches (2–10 Cm.) in width, the lower leaves being stalked, the upper sessile and amplexicaul. They are ovate to ovate-oblong in shape, on each side with one (upper leaves) to five coarse, sinuate teeth or lobes, which are rather acute and oblong or triangular. In the dry state they are of a grayish-green color, glandular-hairy above, more densely so on the lower surface and upon the prominent broad midrib. Some of the characteristic flowers or capsules, or both, may usually be found with the drug, the heavy narcotic odor of which is diminished by drying, but becomes more prominent again when the leaves are moist. The taste is bitter and somewhat acrid. Being very hygroscopic, the leaves should be kept in a dry place. The German Pharmacopœia admits the leaves and flowering-tops.

HYOSCYAMI SEMEN, *U. S.* 1870.—Hyoscyamus-seed, Henbane-seed, *E.*; Semences de jusquiame noir, *Fr.*; Bilsensamen, *G.*—The seeds are no longer recognized by the pharmacopœias, but are employed for preparing

the alkaloid. They are about $\frac{1}{16}$ inch (1.5 Mm.) long, roundish-reniform, flattened; have a gray-brown, finely and densely rough-pitted testa, and contain a whitish oily albumen which encloses a curved embryo of the shape of the figure 9. The hilum is in the concave side of the seed. The seeds are without odor and have an oily, bitter, and acrid taste.

Belladonna-seeds are of about the same size and shape, but are of a red-brown color.

FIG. 154.

*Hyoscyamus*-seed and longitudinal section, magnified 7 diameters.

Constituents.—Brandes (1820) obtained from the seeds 25 per cent. of a bland, limpid, and colorless oil, of which about 20 parts were readily soluble in absolute alcohol. Their most important

constituent, however, like that of the leaves, is the alkaloid *hyoscyamine*, which was observed by Brandes, and again obtained by Geiger and Hesse (1833) and by Kemper (1866) in a purer condition from both the leaves and seeds. More complete investigations were made by Höhn (1870 and 1871), and the exact composition of the alkaloid, its identity with daboisine, and its isomerism with atropine were determined by Ladenburg (1880). For preparing the alkaloid Höhn deprived the seeds of the oil by ether, and then exhausted them by alcohol slightly acidulated with sulphuric acid. The tincture was distilled and evaporated, filtered, almost neutralized with soda, and precipitated by tannin; the precipitate, still moist, was mixed with lime, exhausted with alcohol, the solution again acidulated, concentrated, shaken with ether to remove oil and color, decomposed by soda, and the alkaloid exhausted by ether. The filtrate from the tannin precipitate and the fixed oil retained some of the alkaloid, of which, altogether, 0.0453 per cent. was obtained. Thibault (1875) received it in silky crystals on the spontaneous evaporation of the chloroformic solution. Thorey obtains the alkaloid at once pure by removing the fat from the freshly-powdered seeds by means of petroleum benzin, exhausting with alcohol acidulated with hydrochloric acid, and distilling off the alcohol; the remaining liquid is filtered, deprived of color by benzin, supersaturated with ammonia, agitated with chloroform, and the chloroformic solution evaporated; the dried seeds yield from 0.08 to 0.16 per cent., the leaves 0.042 to 0.224 per cent., and the root 0.006 to 0.307 per cent., of this alkaloid.

Pure hyoscyamine, $C_{17}H_{23}NO_3$, crystallizes in colorless silky needles or is left as a white gelatinous mass; it is permanent in the air, melts at 108.5° C. (227.3° F.), is levogyre, and dissolves rather sparingly in cold water, but is freely soluble in alcohol, ether, and chloroform. Its chemical behavior is very similar to that of atropine (see page 283), but

the double salt with chloride of gold forms lustrous golden-yellow scales which do not melt under boiling water, and in the dry state fuse at 160°C . (320°F). Boiled with baryta-water, the alkaloid is decomposed into a volatile alkaloid and an acid, which, when discovered by Höhn, were named *hyoscyne* and *hyoscynic acid*, but were proven by Ladenburg to be identical with tropine and tropic acid (see page 283). The same author did not succeed in obtaining the salts of hyoscyamine crystallized.

Commercial hyoscyamine is frequently impure, and is then deliquescent, and becomes brown on exposure. It contains a second alkaloid, which Ladenburg (1880) named *hyoscine*, and for which Buchheim (1876) proposed the name *sikeranine*. It is isomeric with hyoscyamine, and has a similar behavior to solvents and on the eye, but is semi-liquid and uncrystallizable; its salts are rather readily crystallizable, and its double salt with chloride of gold is less lustrous, less freely soluble, and melts at 198°C . (388.4°F .); heated with baryta-water, the alkaloid yields tropic acid and *pseudotropine*, $\text{C}_8\text{H}_{15}\text{NO}$, the latter being deliquescent and boiling at 241°C . (466°F).

Höhn (1870) obtained from the seeds also a bitter glucoside, *hyoscyperin*, $\text{C}_{27}\text{H}_{52}\text{O}_{14}$, which has a bitter taste, is neutral, soluble in alcohol and water, and precipitated by tannin; by boiling with diluted hydrochloric acid it is decomposed into fermentable sugar and a yellowish-white resin which melts at 204°C . (399.2°F .), is soluble in alcohol and ether, and has a bitter and somewhat acid taste. In addition to this, a yellow, amorphous, somewhat bitter and slightly acid resin containing nitrogen was found, and on distilling the mother-liquors with soda some volatile bases were obtained, among them, probably, methylamine and ammonia.

Thorey (1869) states that the leaves contain the largest proportion of hyoscyamine and of potassium nitrate before flowering.

Pharmaceutical Preparations.—*OLEUM HYOSCYAMI INFUSUM*.—Oil of hyoscyamus. *E*.—2 parts of hyoscyamus-leaves are left in contact with 1 part of alcohol until the latter is absorbed, when 20 parts of olive oil are added, and the whole digested until the alcohol has evaporated; the oil is expressed and filtered.—*P. G.* 1872.

BAUME TRANQUILLE of the French Codex is a similar preparation, made from the fresh leaves of hyoscyamus, belladonna, stramonium, black nightshade, tobacco, and poppy, of each 40 parts, and of 120 parts of dry aromatic herbs and flowers, comprising twelve kinds, with 1000 parts of olive oil.

Off. Prep.—*Abstractum hyoscyami, U. S.*; *Extract. hyoscyami, U. S., Br.*; *Extr. hyoscyami fluid., U. S.*; *Tinctura hyoscyami, U. S., Br.*

Physiological Action.—*On Animals*: It is implied in the etymology of “hyoscyamus” that the plant may be eaten without harm by hogs; it is also said not to injure sheep or cows, nor to have much effect upon rabbits, while barnyard fowls and fish are poisoned by it. Upon dogs hyoscyamus and its alkaloid act as they do upon man. In them, in cats, and in various other animals, they produce dilatation of the pupil, and in full doses acceleration of the heart’s action and lowering of the temperature, dryness of the mouth, and a dull or lethargic condition, with loss of power in the hind legs. In moderate doses they slow both respiration and circulation, rendering the pulse fuller and stronger; in large doses they have the opposite effect. They increase the discharge of urine, from which the alkaloid can be recovered. These effects are so nearly like those occasioned by belladonna and atropine that some pharmacologists regard the latter alkaloid and hyoscyamine as identical.

On Man: The following effects are produced by henbane and by hyoscyamine: In full medicinal dose the former occasions headache, pasty mouth, hoarse voice, dry throat, a warm skin, and a slower and then an accelerated pulse, while the pupil becomes dilated and vision indistinct, and the limbs give way under the body. The sense of touch is blunted, and the voluntary muscles are apt to be cramped or to be affected alternately with spasm and paralysis. No direct narcotic effect is produced in the greater number of cases, but rather a loquacious sub-delirium, with hallucinations, which may merge into a restless and dreamy sleep. Only in large doses is it decidedly hypnotic. The power of henbane to produce a peculiar talkative and pugnacious delirium was fully described by ancient writers, and some modern observers have witnessed similar effects. It is curious that in certain cases, although the general sensibility is impaired, severe neuralgic pains may be felt in the limbs. Continued medicinal doses tend to produce a reddish efflorescence upon the skin, which is dry and itching. When poisonous doses, on the other hand, have been taken, the skin is sometimes cool and clammy, the face pale, and the lips bluish. Notwithstanding the threatening character of the symptoms, death from this substance is extremely rare. A maniacal patient to whom $\frac{1}{4}$ grain of amorphous

hyoscyamine were given became comatose, the pupils were only slightly dilated, the capillaries were injected, the pulse 150, respiration was short and rapid, the jaw dropped, the eyelids were partly closed, and the eyeballs exposed and turned upward. In this condition he remained for 4 hours, but after that time, though he was drowsy and stupid, he could easily be aroused (Gill). The most striking example of its effects is furnished by Dr. H. A. Hutchinson of Pittsburg, who took $\frac{1}{4}$ grain of Merck's hyoscyamine (*Phila. Med. Times*, xiii. 139). Besides the dryness of the mouth and throat, there was intense congestion of the head and face and violent throbbing of the heart and carotids, numbness over the whole body and muscular incoördination, and an inability to walk without watching the steps. There was no mental excitement or sensory illusion, but an overpowering tendency to sleep, which came on and lasted for 11 hours. Various means were used by friends who were ignorant of the cause of the sopor to arouse the sleeper, but they availed nothing. During the sleep the muscular system was completely relaxed, and the pulse at first was full and hard, beating 138 a minute, the respirations 34 to 40, and the temperature 106° F. As the narcotism subsided these rates subsided rapidly toward the normal standards. On regaining consciousness the mind was unsteady and confused, and all objects looked tinged with yellow. During the sleep there was more or less nausea, and once vomiting. No recollection of anything after the commencement of sleep remained. For several days the pupils remained dilated, and there was double vision, while all the secretions, including the perspiration, were suspended. A patient of Empis affected with *paralysis agitans* took 5 Mgm. of hyoscyamine (gr. $\frac{1}{3}$), and, finding the tremor diminished, used a like quantity on the following day. The first dose caused a slight intoxication, and after the second there was a like confusion of the mind and senses, the face was flushed, the expression anxious, the whole interior of the mouth dry, the tongue stiff, and nausea was experienced. Hallucinations in which rats and serpents appeared and familiar persons were not recognized were accompanied and followed by furious delirium, tetanic spasms, and extreme dilatation of the pupils. Deglutition was impossible; the respiration was hurried and oppressed, the pulse at 96; and constant vesical tenesmus existed. The attack lasted for 3 hours, and gradually subsided, and on the morrow only some recollection of the hallucinations remained (*Bull. de thérap.*, xcix. 373). A phthisical patient accustomed to hypodermic injections of morphia was given $\frac{1}{30}$ grain of hyoscyamine. After vomiting he became delirious, lost all correct perception of the distance of objects, and constantly caught at insects, with which he said his bed-clothes were covered (*Practitioner*, xxii. 369). No death has been directly caused by hyoscyamine. In proportion to the dose the symptoms are less alarming in children than in adults, and especially in old persons. This peculiarity is doubtless due to the rapid elimination of the poison in the young. From an experimental point of view it must be concluded that, unless in very large doses, hyoscyamus is not so much a narcotic soporific as an anodyne or anæsthetic, that it excites the cerebral and depresses the spinal functions, and that it is a mydriatic.

According to Gnauck, *hyosceine* is tenfold stronger than hyoscyamine, even a very minute dose (gr. $\frac{1}{600}$) invariably producing its characteristic effects, and subcutaneously acting twice as powerfully as by the mouth. He thinks that it tends directly to slow the pulse (*Phila. Med. News*, xl. 323). Emmert has proposed "hydriodide of hyosceine" as superior to any other form of the active principle of hyoscyamus, and also to atropine and duboisine (*Med. Record*, xxi. 403). It should be noted that the hyoscyamine of commerce is rarely genuine. Regnaud and Valmont (*Archives gén. de Méd.*, Jan. 1881, p. 15) state that crystallized hyoscyamine is, sometimes at least, atropine mixed with some foreign substance, and that hyoscyamine has not really been procured in a crystalline form.

Medical Uses.—At one time hyoscyamus was believed to be a valuable remedy for *epilepsy*, but experience has shown that the doses formerly given were quite inert, and that even in really operative doses its utility is limited to cases of emotional origin. Dr. Lawson in England found hyoscyamine very useful in controlling violent outbreaks of *mania*, especially of the recurrent acute and subacute forms, the monomania of suspicion, and the excitement of senile dementia. He regarded it as essential to the success of the treatment that the medicine should be given in a dose not less than 1 grain. If a smaller dose is taken, it is said cerebral excitement, without complete motor paralysis, is produced, and remains through the whole period of the operation of the medicine. Mr. Gill, physician to the Lunatic Hospital, York (Eng.), on the other hand, recommended a dose varying from $\frac{1}{4}$ to $\frac{3}{4}$ grain; and that in exceptional cases $\frac{3}{4}$ grain, or even a grain, might be given with safety. In some forms of *hypochondriasis* it seems to have been useful as a means of

calming agitation. Prolonged experience has confirmed these statements. Thus we learn from Prideaux (*Practitioner*, xxiii. 446) that it produces sleep, sometimes of considerable duration, in excited conditions of the brain, as in *mania*, *delirium tremens*, *meningitis*, and where ordinary hypnotics, and especially opiates, are inadmissible. In such cases small doses ($\frac{1}{16}$ gr.) suffice, but in chronic mania large doses ($\frac{1}{2}$ grain, or even 1 grain) are necessary, and are very useful in cutting short exhibitions of temper and excitement of a violent and destructive character. It would appear to be particularly useful in delusional *insanity*; the illusions which it conjures up overlie and gradually obliterate those which belong to the disease. "In chronic *dementia*, associated with destructive tendencies, bad habits, and sleeplessness," the patients are much improved by a course of small doses of the drug. Dr. Gray, superintendent of the State Medical Asylum of New York, confirms these observations by his own experience, but recommends a combination of hyoscyamine and morphine where there is a failure of cerebral energy; and, on the other hand, when violence predominates he associates the hypodermic use of hyoscyamine with the internal exhibition of the bromides (*Practitioner*, xxvi. 299). These results are confirmed by those of Bacon (*Practitioner*, xxvii. 367), Seguin (*Med. Record*, xvii. 354), Gnauck (*Amer. Jour. of Med. Sci.*, Oct. 1883, p. 556), and many others. Seguin particularly corroborates the favorable action of the drug in delusional insanity with insomnia (*Med. Record*, xix. 712). In puerperal insanity the action of the medicine is most advantageous. In functional *palpitation* of the heart of a purely nervous nature it has been found beneficial, when used hypodermically, in the dose of about $\frac{1}{50}$ grain (Gm. 0.001). The same means relieve cardiac and pulmonary *asthma*. Hyoscyamine has been used in trembling *palsy* and mercurial *trembling*, *epilepsy*, *chorea*, *locomotor ataxia*, and *tetanus*. In the first it exerts a marked power in moderating the tremulousness, and in the second it is alleged to have effected cures. In the epileptic status in *epileptic mania* it diminishes the number, frequency, and severity of the attacks (Prideaux), and it is one of the most efficient means of procuring sleep in *delirium tremens* when the patient is at the same time properly fed. It seems to have cured a number of cases of *chorea*, of which several occurred in adults, but other preparations of hyoscyamus have but little influence on the disease; in locomotor ataxia it palliates the spasms and the neuralgic pains, and in tetanus moderates the severity of the paroxysms. In these affections, and notably in *chorea*, its therapeutical action may be explained by its paralyzing influence upon the spinal cord, which seems to be of the same nature as that produced by conium. The *vomiting* of pregnancy, a symptom of reflex origin, has been controlled by it. It was prescribed in a solution containing 5 Mgm. (gr. $\frac{1}{16}$) of the alkaloid in 125 Gm. (f $\bar{5}$ iv) of liquid, of which a teaspoonful was given every hour.

There is no doubt that hyoscyamus is anodyne, and apparently by its operation upon the sensitive nerves and ganglia, and not upon the cerebral organs of perception. The crushed leaves of fresh henbane are popularly applied where the plant abounds for the relief of local pains, and internally its preparations are of common use to allay *neuralgia* and other pains that hinder sleep. It is also used to lessen the tendency to gripe of certain cathartics given in a pillular form, for it has the advantage of relaxing rather than confining the bowels. Like the other mydriatics, henbane (hyoscyamine) is used to dilate the *pupil*. *Poisoning* by henbane should be treated by evacuating the stomach, applying warmth to the extremities and cold to the head, and administering stimulants, particularly coffee, and morphia hypodermically in small and repeated doses. It is recommended not to give hyoscyamine to patients with degenerate arteries or chronic cardiac disease, or to very old people.

The *dose* of powdered henbane is stated at from 5 to 15 grains (Gm. 0.30–0.60), but this form of the medicine is rarely used. Hyoscyamine may be given in the dose of 1 Mgm. or $\frac{1}{65}$ gr., repeated at intervals of several hours, or, if not for a temporary purpose, this dose should be prescribed twice a day, and gradually increased until its characteristic effects are observed in the pupils and in the throat. But in cases of great functional excitement or disorder from $\frac{1}{4}$ grain to 1 grain (Gm. 0.016–0.06) may be given by the mouth. Hypodermically, its action is relatively far more powerful than when it is given by the stomach, but the dose of $\frac{1}{65}$ gr. can generally be administered in the cases here referred to.

In addition to the formula given above, the following is recommended (Gill): $\mathcal{R}$. Hyoscyaminæ gr. x; spt. vin. rect. $\bar{3}$ j; ætheris sulph. f $\bar{5}$ iv. The two latter are mixed, and this mixture will fully dissolve the hyoscyamine; then water is added to make the whole 20 ounces. This solution contains $\frac{1}{2}$ grain of hyoscyamine to the ounce.

HYPERICUM.—ST. JOHN'S WORT.

Millepertuis, Casse-diable, Fr. ; Johanniskraut, Hartheu, G.

Hypericum perforatum, Linné.

Nat. Ord.—Hypericaceæ.

Description.—This plant grows in fields and on roadsides throughout Europe, Northern Africa, and a considerable portion of Asia, and has been extensively naturalized in North America and in other countries. It has a perennial woody and branching dark-brown root and a somewhat two-edged stem about 2 feet (60 Cm.) high. The leaves are opposite, sessile, oblong or linear-oblong, nearly an inch (25 Mm.) long, obtuse, entire on the margin, and pellucid-punctate. The flowers are in open terminal cymes, deep-yellow, nearly an inch (25 Mm.) broad, and are furnished with numerous stamens clustered in three groups, and with a three-celled ovary. The petals, anthers, leaves, and stem are more or less marked with black dots. When bruised the herb has a slight balsamic odor; its taste is somewhat resinous, bitter, and slightly astringent. The flowering-tops, on drying, lose from 60 to 65 per cent. in weight.

Constituents.—Buchner (1830) found in the flowers a little tannin, producing a dark-green color with ferric salts, some pectin, and 8 per cent. of a red coloring principle, *hypericum red*, which is soluble in alcohol, ether, volatile oils, and warm olive oil, and dissolves with a green color in ammonia and other alkalis; calcium and lead salts produce yellow precipitates, ferric chloride a yellowish-green one. According to Clamor-Marquart, this coloring matter is a mixture of a red and a yellow principle, and is mainly contained in the black glands.

Pharmaceutical Uses.—The fresh flowering-tops, digested with olive oil sufficient to cover them, yield a yellowish-red liquid, *Oleum hyperici*, which is popularly known as *red oil*. Linseed oil is sometimes used in place of olive oil.

Allied Plants.—Several other European species of *Hypericum* possess similar properties, and some of our North American species may be equally effective.

HYPERICUM SAROTHTRA, Michaux (Sarothra gentianoides, Linné, s. Sar. hypericoides, Nuttall). has thin almost thread-like branches, opposite awl-shaped scaly leaves, and minute sessile yellow flowers. It is common in sandy fields in the United States, where it is known as *orange-grass* or *pine-weed*, and is sometimes used like the preceding.

ASCYRUM CRUX-ANDREE, Linné (St. Andrew's cross), is a decumbent North American herb with narrow oblong-obovate leaves and solitary flowers, having the four linear-oblong yellow petals arranged in the form of a cross.

Medical Action and Uses.—The aromatic and terebinthinate odor of this plant when it is crushed in the hand, and its resinous and bitter taste, sufficiently account for the vogue which it enjoyed in certain diseases even from ancient times. It was celebrated by Celsus, Paulus Ægineta, Galen, and Dioscorides, and its vogue only declined when modern science substituted for it medicines whose remedial effects were conceived to be more intelligible. The titles it bore indicate its popular estimation; they were such as these: "St. John's Wort," "The Lord God's Wonder-Plant," "The Devil's Scourge," "The Witches' Herb," and many similar. The ancients attributed to it stimulating, drying, cleansing, and cicatrizing virtues, and held it to be diuretic and emmenagogue and a specific remedy for wounds, ulcers, and burns. In the Middle Ages analogous virtues were ascribed to it, as well as curative powers in calculous affections, intestinal worms, and mental disorders. In more recent times it was given for the relief of chronic *catarrhs* of the *lungs, bowels, and urinary passages*, and was especially esteemed in the last. It was also used in hot infusion to bring on retarded *menses*. Externally, it was applied in the fresh state, bruised, as a discutient for recent *contusions* and for the relief of local *pains*. Its flowers, immersed in olive oil in a bottle and hung in the sun for a month or two, give to the oil a dark-red color (red oil), forming one of the most popular applications made to *excoriations, wounds, and bruises* both in Europe and in this country. An infusion may be prepared with an ounce (Gm. 32) of the plant in a pint of hot water.

HYSSOPUS.—HYSSOP.

Hysope, Fr. ; Isop, Ysop, G.

Hyssopus officinalis, Linné.

Nat. Ord.—Labiatae, Satureieae.

Description.—Hyssop is an herbaceous perennial indigenous to Southern Europe,

frequently cultivated and sparingly naturalized in the United States. It is about a foot (30 Cm.) high, with wand-like simple quadrangular branches and opposite, sessile, linear-lanceolate, entire, and nearly obtuse leaves, which are about an inch (25 Mm.) long, nearly smooth, and finely punctate on both sides. The purplish-blue flowers are in small clusters, and have a fifteen-ribbed calyx, a two-lipped corolla with a rather short and notched upper lip, and four exserted and divergent stamens. Hyssop has an aromatic somewhat camphoraceous odor and a pungent, aromatic, and bitterish taste.

Constituents.—Aside from tannin, resin, fat, sugar, mucilage, etc., the most important constituent is *oil of hyssop*, of which the fresh herb yields $\frac{1}{4}$ to $\frac{1}{2}$ per cent. It is pale-yellow or greenish, limpid, of about the specific gravity 0.94, and freely soluble in alcohol, it contains oxygen, and commences to boil at 142° C. (287.6° F.), the boiling-point rising to 180° C. (356° F.). It has the odor and taste of the herb. The *hyssopin* of Herberger (1829) was found by Trommsdorff to be impure sulphate of calcium.

Allied Plants.—*CYNILA MARIANA*, *Linné* (*Dittany*), a North American plant, grows in dry soil, has a thin, purplish, much-branched stem, about 12 inches (30 Cm.) high, and nearly sessile, ovate, serrate, smooth leaves, which are rounded or subcordate at the base. The pale-purple flowers are in small pedunculate clusters and have two exserted stamens.

SATUREJA HORTENSIS, *Linné*.—Summer savory, *E.*; *Sarriette*, *Fr.*; *Saturei*, *Bohnenkraut*, *G.*—This South European annual is cultivated as a culinary herb. The stem is about 10 inches (25 Cm.) high, much-branched, roughish-pubescent; the leaves are linear-lanceolate or oblong-linear, entire, acute, and tapering into a very short petiole; the cymules are about three-flowered, with the corolla pale-purplish, and with four diverging rather included stamens.

SATUREJA MONTANA, *Linné* (*Micromeria*, *Reichenbach*).—Winter savory, *E.*—It is suffruticose, retrorsely hairy, and has hairy whitish or reddish flowers in small axillary clusters, and linear-lanceolate, mucronate, and pellucid punctate leaves about $\frac{3}{4}$ inch (18 Mm.) long and rough on the margin. Haller (1882) obtained from it .83 per cent. of volatile oil having an orange-yellow color, an odor resembling that of origanum, and the density .7394 at 17° C.; it is levogyre, and contains two hydrocarbons and two phenols, one of the latter being identical with *carvacrol*.

PYCNANTHEMUM LINIFOLIUM, *Pursh* (*Virginia thyme*), has rigid, narrowly linear sessile crowded leaves, which are entire and three-nerved; the flowers are in terminal hemispherical clusters, supported by imbricate, rigidly-pointed bracts. It has been popularly regarded as useful in hydrophobia, and has been employed in atonic dyspepsia.

PYCN. LANCEOLATUM, *Pursh*, resembles the preceding, but has lanceolate or lance-linear leaves; both have a resinous and bitter taste.

PYCN. INCANUM, *Michaux*, has broader ovate-oblong, hoary, pubescent leaves and an aromatic mint-like taste. It is known as *mountain-mint*, *wild basil*, and in some places as *horse-mint*, and is used like *Monarda*.

Ch. Mohr (1876) isolated from *Pycn. linifolium* a tannin which is very similar to, if not identical with, caffen-tannic acid; volatile oil, resin, bitter principle, etc. were likewise obtained.

THYMUS VULGARIS, *Linné* (Bentley and Trimen, *Med. Plants*, 205); *Herba thymi*, *P. G.*—Garden thyme, *E.*; *Thym*, *Fr.*; *Thymian*, *Römischer Quendel*, *G.*—A small South European suffruticose plant which is often cultivated for culinary purposes. The leaves are $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–8 Mm.) long, ovate-oblong or linear, revolute on the margin, grayish-green, glandular, punctate on both sides and pubescent beneath, the upper ones bearing in their axils small clusters of whitish or reddish flowers with exserted stamens.

THYMUS SERPYLLUM, *Linné*; *Herba serpylli*, *P. G.*—Wild thyme, *E.*; *Serpolet*, *Fr.*; *Quendel*, *Feldthymian*, *G.*—It is a common prostrate suffruticose plant indigenous to Europe and Northern Asia and to some extent naturalized in North America. The leaves are $\frac{1}{2}$ or $\frac{3}{4}$ inch (5 or 10 Mm.) long, petiolate, flat, ovate or roundish-lanceolate, occasionally linear, entire, ciliate near the base, glandular on both sides, otherwise smooth. The purple or rose-colored flowers are aggregated in heads or dense spikes terminating the branches, and have the four stamens included or sometimes exserted. It is a variable plant, including several nominal species, among them *Thymus citriodorus*, *Schreber*, the *lemon-thyme*, which has an agreeable odor resembling that of melissa and of lemon. Both thymes have a strong aromatic odor due to volatile oil. (See *OLEUM THYMI*.)

MICROMERIA DOUGLASSII, *Bentham*, s. *Mic. barbata*, *Fischer et Meyer*. It is a perennial, creeping or trailing, sweet-scented herb of the Pacific coast from California to Washington Territory, and is known as *yerba buena*. The leaves are about an inch (25 Mm.) long, roundish-ovate, thin, sparingly toothed and short-petioled; the purplish flowers are mostly solitary in the axils on long and filiform peduncles.

Medical Action and Uses.—Anciently hyssop seems to have been used as a cathartic, for we read in Scripture, "I will purge thee with hyssop, and thou shalt be clean;" and, if this passage be thought to apply to external cleansing, Pliny says expressly that "mixed with figs it purges, and with honey vomits." He also refers to its external use in phthiriasis. Down to a quite recent period it was used to improve digestion, particularly in atonic and flatulent *dyspepsia*, and, like other plants which are so employed and contain an essential oil associated with a bitter and astringent principle, it is found useful in subacute and chronic *bronchitis*, especially in old persons, also in *amenorrhœa*, and externally

as a stimulant application to *bruises* and in muscular *rheumatism*. Its infusion was also employed as a gargle in *sore throat* of the diphtheritic form. Hyssop may be given in an infusion made with a drachm (Gm. 4) of the herb to a pint of water. The essential oil was formerly given in doses of 1 or 2 drops (Gm. 0.06–0.12).

Summer savory has essentially the same medicinal virtues as the other plants in this group. It is also used as a vermifuge and as a cure for the itch. *Garden thyme* is used in domestic medicine for the purposes just mentioned, but especially to promote the digestion of certain fatty meats, such as pork and goose, or to give a flavor to insipid dishes.

Wild thyme is held to be still more efficacious than garden thyme as a stimulant in all functional affections associated with exhaustion of the system, including, besides the above, whooping cough, headache from alcohol, passive hæmorrhages, etc. *Ditana digitifolia*, a native plant of Brazil, is reputed to be a galactagogue (*Med. Record*, xx. 420).

ICHTHYOCOLLA, U. S.—ISINGLASS.

Colla piscium.—*Fish glue*, E.; *Colle de poisson*, *Ichthyocolle*, F.; *Hausenblase*, *Fischleim*, G.

The swimming-bladder of *Acipenser Huso*, *Linne*, and of other species of *Acipenser*.

Class Pisces. Ord. Sturiones.

Origin.—Isinglass is mentioned by the British Pharmacopœia among the articles employed in chemical testing. The kind preferred is that known in commerce as *Russian isinglass*, which is obtained from several sturgeons, species of *Acipenser*, which inhabit the Caspian and Black Seas and their tributary rivers, and the most important of which are *Ac. Huso*, *Linne*, or *belugo*; *Ac. Güldenstädtii*, *Ratzeburg*, or *osseter*; *Ac. ruthenus*, *Linne*, or *sterlet*; and *Ac. stellatus*, *Pallas*, or *sevruga*. It is prepared by cutting the air-bag or swimming-bladder open, washing and soaking it in water, and spreading it upon boards, the outer silvery membrane being turned upward and removed by rubbing. The bladder is then merely dried in sheets, and constitutes *leaf isinglass*, or several are put together and folded before they are completely dry, forming *book isinglass*, or each bladder is rolled up and folded around a few pegs in the form of a horseshoe, heart, or lyre, in which shape it is dried. The latter is the *staple isinglass*, which, according to its dimensions, is again divided into *long* and *short staple*. The kind now most commonly met with in our commerce is the *leaf isinglass*.

Description.—Russian isinglass is a somewhat horny and tough membranous tissue, which is semi-transparent, of a whitish or pale-yellowish color, pearly appearance, and iridescent; it is best torn in the direction of its fibres, is inodorous, and quite insipid in taste. Immersed in water or diluted alcohol, it swells, becomes opaque, and dissolves at a somewhat elevated temperature, leaving a flocculent residue not exceeding 2 per cent.; on cooling, its solution with 24 parts of water congeals to a transparent jelly. On incineration, it leaves 0.5 per cent. of ash. Isinglass which is discolored or less soluble in water is not adapted for medicinal purposes.

Off. Prep.—*Emplastrum ichthyocollæ*, U. S.

Constituents.—Besides membranous matter and some salts, isinglass consists of that variety of gelatin known to chemists as *glutin*. (See GELATINA, page 725.)

Adulterations.—In the place of Russian isinglass the swimming-bladder of other fishes is sometimes sold, and the intestines of various animals are said to be coated with gelatin and used for a like purpose. Such substitutions or adulterations are easily recognized by the larger amount of ash (3 to 10 per cent.) left on incineration or by the larger proportion of matter insoluble in hot water. Gelatin immersed in cold water swells, retains its transparency, and becomes soft and easily disintegrated.

Other Varieties of Isinglass.—The air-bags of most large fishes appear to be adapted for some of the purposes for which isinglass is used in the arts; when they are dried without being split open they are known as *purse* or *pipe isinglass*.

American isinglass, according to C. T. Carney (1857), is prepared from the sounds of *Gadus merluccius*, *Linne*, or *hake*; they are cleansed, soaked in water, passed through rollers, and dried in the form of ribbons or thin and transparent sheets. C. C. Meyer (1873) found the former to leave 30 per cent., and the latter only 18 per cent., of matter insoluble in water; the fresh bladder of a hake weighing 15 ounces left 1 ounce undissolved. Storer states that the swimming-bladder of *Otolithus regalis*, *Cuvier*, the *weakfish*, likewise furnishes some isinglass.

Brazilian isinglass comes from species of the genera *Pimelodus* and *Silurus*, the entire sounds being often dried so as to adhere together (*lump isinglass*), and the lumps are sometimes split open (*honeycomb isinglass*). A false isinglass from Para consisted, according to Pereira (1853), of the ovaries of a fish, probably *Sudas gigas*.

East Indian isinglass is produced from several large fishes, and is met with in the form of purses and of leaves.

Japanese or Chinese isinglass is a vegetable product. (See CHONDROS.)

Medical Action and Uses.—Isinglass was anciently applied as a protective to the skin when it was *abraded* or affected with *eruptions*. It is emollient and nutritive, and forms a valuable addition to boiled milk or to farinacea prepared with milk in treating the chronic bowel complaints of children. In court-plaster it is used for its adhesive qualities.

IGNATIA, U. S.—IGNATIA.

Semen Ignatiæ, Faba Ignatii.—*Bean of St. Ignatius, E.; Fève de Saint-Ignace, Fève igasurique, Fr.; Ignazbohne, G.*

The seed of *Strychnos Ignatia*, *Lindley* (*Str. Ignatii, Bergius, s. Str. philippensis, Blanco, s. Ignatiana philippinica, Loureiro, s. Ignatia amara, Linné filius*). *Bentley and Trimen, Med. Plants*, 179.

Nat. Ord.—Loganiaceæ.

Origin.—This is a large climbing shrub indigenous to the Philippine Islands and naturalized in Cochin China, with opposite ovate leaves and an oblong or subglobular berry-like fruit having a brittle pericarp and containing about twenty-four seeds imbedded in a bitter pulp.

Description.—The seeds are from 1 to 1½ inches (25–31 Mm.) long, ¼ to ½ inch (12–20 Mm.) broad, oblong, ovate or roundish-ovate in shape, by mutual pressure irregularly angular; the hilum is on one of the edges in a small depression, and the surface of the seeds is of a dull reddish-gray or brownish, when old even blackish, color, and granular or partly covered by gray or light-brown silky hairs. *Ignatia* consists of a very hard, horny albumen, which is of the shape of the seeds and translucent at the edges, and surrounds an irregular cavity. The embryo projects into this cavity, and consists of a rather long radicle and oblong-ovate acute cotyledons. The seeds break under the hammer with a granular and irregular fracture, and soften after prolonged digestion. They are inodorous and have a very persistent bitter taste.

Constituents.—Pelletier and Caventou (1819) found the seeds to contain the same constituents, though in different proportions, as *nux vomica*; they stated the yield of strychnine (still containing brucine) to be 1.4 per cent. Geiseler (1837) likewise found 1.5 per cent. of this alkaloid. F. F. Mayer (1863), on assaying *ignatia* with his solution, obtained from 2 troyounces of the seeds 4.5 grains of strychnine and 13.73 grains of brucine, which correspond to 0.52 per cent. of the former and 1.43 per cent. of the latter. The dried seeds yield 1.78 per cent. of nitrogen, indicating about 10 per cent. of albuminoids (*Pharmacographia*).

Off. Prep.—*Abstractum ignatiæ, Extractum ignatiæ, U. S.*

Medical Action and Uses.—The action and uses of *ignatia* are identical with those of *nux vomica*. Its *dose* may be said to range from ½ grain to 2 grains (Gm. 0.03–0.10).

FIG. 155.
Ignatia: vertical section of seed.

ILEX.—HOLLY.

Houx, Fr.; Stechpalme, Christdorn, G.

The leaves of different species of *Ilex*.

Nat. Ord.—Aquifoliaceæ.

Origin and Description.—*ILEX OPACA, Aiton (American holly)*. It is indigenous to the United States, and is either shrubby or a tree 30 or 40 feet (9 or 12 M.) high. The leaves are petiolate, coriaceous, and evergreen, about 2 inches (5 Cm.) long, oval in shape, and with a wavy-toothed margin, the teeth being furnished with rigid and sharp spines. They are without odor and have a mucilaginous, bitterish, and astringent taste.

ILEX AQUIFOLIUM, Linné (European holly), is very nearly related to the preceding. The leaves differ in being rather ovate, dark-green and glossy on the upper surface.

ILEX CASSINE, Linné (known as *yaupon, youpon, or cassena*). It grows in the United States from Virginia southward. The leaves are shortly petiolate, about 1 inch (25 Mm.) long, coriaceous, varying in shape between lance-ovate, ovate, and oblong, crenate on the margin, smooth, dark-green, and glossy above, and paler beneath. They are inodorous, and have an astringent and bitterish taste.

The following two species are likewise known as *cassena* in the Southern States :

ILEX DAHOON, *Walter*, has leaves about 2 inches (5 Cm.) long, which are oblong or oblanceolate, with the margin revolute or entire or sharply serrate toward the apex.

ILEX MYRTIFOLIA, *Walter*. The leaves are linear-lanceolate or linear-oblong, 1 inch (25 Mm.) long, entire on the margin or furnished with a few sharp teeth.

The fruit of these species is a red drupe, usually containing four one-seeded ribbed or grooved nutlets.

ILEX PARAGUAYENSIS, *St. Hilaire*, is a small tree indigenous to Brazil and the Argentine Republic. The leaves are oblong or lanceolate, wedge-shaped at the base, rather obtuse at the apex, and with distant teeth on the margin. They furnish the *yerba mate* or *Paraguay tea*, also known as *Jesuits' tea* and *St. Bartholomew's tea*, which is extensively used in South America, the annual consumption in the Argentine Republic alone being estimated at 27,000,000 pounds, or about 13 pounds per head. It is prepared as follows: The small branches with the leaves are placed in the *tatacúa*, a plot of earth about 6 feet (1.8 M.) square, surrounded by fire, where they undergo their first roasting. They are thence taken to the *barbacúa*, which is a grating underneath which burns a fire, where they are somewhat torrefied to develop the aromatic principle. The leaves are subsequently reduced to powder in a sort of mortar formed of pits dug in the earth and well rammed. More recently, suitable furnaces have been erected for drying and torrefaction, and mills are used for powdering. According to Peckolt, the leaves possess most aroma when the fruit is nearly ripe, and are collected in different parts of South America from December or January till the following August or September.

Constituents.—The leaves of the European holly were examined by Lassaigne (1822), Déleschamps (1832), Lebourdais (1841), Moldenhauer (1857), and Bennemann (1858). The four first-named investigators obtained the bitter principle as a more or less colored amorphous mass; Bennemann, in the form of feathery crystals too small in quantity for further investigation. Déleschamps' *ilicin* was *not*, but Moldenhauer's and Bennemann's *was*, precipitated by subacetate of lead; Lebourdais's *ilicin* was absorbed from the decoction by animal charcoal and extracted from it by boiling alcohol. D. P. Pancoast's (1856) *ilicin* was obtained by Lebourdais's process from the fruit of the American holly, and is described as being in minute needles; the same process applied to the leaves yielded an amorphous green mass.

Moldenhauer isolated *ilixanthin*, $C_{17}H_{22}O_{11}$, the yellow coloring matter of the leaves, in the form of straw-yellow needles which are soluble in alcohol and boiling water, but insoluble in ether. *Ilicic acid* is syrupy; its barium salt is amorphous; the calcium salt crystallizes in scales.

The yaupon contains 0.122 per cent. of *caffeine*, 2.409 per cent. of tannin, 4 per cent. of ash, besides wax, resin, etc., according to the analysis of H. M. Smith (1872). Caffeine was also found in mate by Stenhouse (1843), who regards the tannin as differing somewhat from caffeeo-tannic acid. Rochleder, on the contrary, considered the tannin from the two sources as identical, but, according to Arata (1877), *mateo-tannic acid* gives with baryta-water a green, and with lead acetate a yellow-greenish, precipitate, and its precipitate with gelatin is insoluble in the tannin solution; like caffeeo-tannin, it is not precipitated by tartar emetic, and on dry distillation yields pyrocatechin. Alonzo Robbins (1878) examined seven samples of maté, and found the caffeine to vary between 0.2 and 1.6 per cent. and the tannin between 10 and 16 per cent.; the samples containing the largest amount of caffeine yielded the least tannin, and *vice versa*. Stenhouse had found 0.13 (in 1843) and 1.2 (in 1851) per cent. of caffeine. According to Peckolt, the average is 0.5 per cent., and the air-dried leaves vary to about the same extent as maté in the percentage of caffeine; 0.24 per cent. of crystallizable mateviridic acid is present in both, also a minute quantity of volatile oil and stearopten.

Medical Action and Uses.—According to Barbier, holly-leaves and their preparations produce a sense of heat and oppression in the stomach, with some nausea, followed by colic without diarrhoea. The berries vomit and purge, and at least one case is recorded of their proving fatal to a child. The leaves, being bitter, were naturally employed for the cure of *intermittent fever*, and a formal inquest upon their virtues having been held by the Institute of France, its chairman reported that their efficiency was real, although it was very slow in exhibiting itself. He was probably unacquainted with the fact that intermittent-fever patients removed to a hospital generally recover without medicinal treatment. Moreover, subsequent clinical observations by competent physicians proved that the curative power of the medicine in this disease is absolutely null. The leaves have been used in *rheumatism*, internally and topically, and the berries

as cathartics in *dropsy*. An American species, *I. opaca*, is demulcent, and is used in decoction to palliate *cough* and promote expectoration. *I. paraguayensis*, or Paraguay tea, is employed in its native country very much as Chinese tea is used elsewhere, and for similar purposes and with like effects, or, more precisely, with effects like those of coca. According to Couty (1879), when its infusion was injected into an animal's stomach it excited efforts to urinate, with priapism and quickening of the pulse (*Archives gén. de Méd.*, 7 sér. iii. 239). In 1881, Couty and Arsonval declared that it "diminished the carbonic acid and the oxygen of the arterial blood to the extent of one-third or even one-half," and that thus it exerted a powerful influence upon the nutritive function (*Bull. de thérap.*, ci. 81). Its infusion is said to be sudorific or diuretic, and in large doses drastic.

ILLICIUM, U. S.—ILLICIUM.

Fructus (Semen) anisi stellati, Semen badiani.—Star-anise, Chinese anise, E.; *Badiane, Anise étoilé, Fr.*; *Sternanis, G.*

The fruit of *Illicium anisatum*, *Loureiro*. Bentley and Trimen, *Med. Plants*, 10.

Nat. Ord.—Magnoliaceæ.

Origin.—This is a shrub or small tree 8 or 10 feet (2.4 or 3.0 M.) high, with ever-green lanceolate, entire, pellucid-punctate leaves and greenish-yellow polypetalous flowers. It is indigenous to the high mountains of Yunnan in South-western China and to the west of Canton. During the year 1866–67 there were imported into the United States 17,307 pounds of star-anise; more recent returns include the drug with anise.

Description.—Star-anise consists of about eight boat-shaped foliicles, which are horizontally arranged in one circle around a pedunculate short axis. The foliicles are about $\frac{1}{2}$ to $\frac{3}{8}$ inch (12–15 Mm.) long, have a shallow depression above near the apex, and a straight beak, which in the commercial article is usually partly broken off; they are rather woody, externally wrinkled and brown, internally smooth, red-brown, and glossy, and on the upper margin usually split open. Each carpel has a single seed, which is oval, flattened, oblique at the base, smooth, and of a polished brown-yellow color, and contains a large oily albumen enclosing the small embryo. Star-anise yields about 78 per cent. of capsular integuments, which have a very agreeable anise-like odor and a sweetish aromatic taste. The seeds weigh about 22 per cent., are but slightly aromatic, and have an oily taste. The poisonous fruit of *Ill. religiosum*, described below, has been occasionally mixed with star-anise.

FIG. 156.

Star-anise.

Constituents.—The fruit and seeds were separately examined by Meissner (1818), who obtained from the former 5.3 per cent. of volatile oil, 2.8 of fat, 10.7 of resin, etc.; the fruit seems also to contain a little tannin, mucilage, and pectin. The seeds were found by Meissner to yield only 1.8 per cent. of volatile oil and 2.6 per cent. of resin, but about 20 per cent. of fixed oil. The volatile oil is chemically identical with that of *Pimpinella Anisum*. (See *OLEUM ANISI*.) According to Eykman (1880), the fruit contains an alkaloid, which has not been further examined.

Allied Plants.—*ILLICIUM RELIGIOSUM, Siebold*. This has usually been regarded as identical with the preceding, until attention was directed to the important distinctions by Geerts, Eykman, and Holmes in 1880. The plant is indigenous to Eastern Asia, and is often cultivated in Japan near the temples; it is a tree 25 to 30 feet (7.5–9 M.) high, with broader and more glaucous leaves and with an aromatic bark. The fruit, like the preceding, consists of eight foliicles spreading horizontally, but only a portion of these are usually developed to maturity; each follicle is about $\frac{1}{2}$ or $\frac{3}{8}$ inch (3 or 10 Mm.) long, is woody, often shrivelled, has near the apex a short and rather deep depression, terminates with a short curved beak, and has a faint clove-like odor and an unpleasant taste. The plant is known in Japan as *sikimi* or *shikimi*. Eykman found in the fruit an alkaloid and a poisonous neutral principle, *sikimin*, which crystallizes in hard prisms or needles, is insoluble in petroleum benzin, slightly soluble in cold water, more freely soluble in hot water, ether, and chloroform, and easily soluble in alcohol and glacial acetic acid. The volatile oil is somewhat heavier than water, slightly levogyre, reduces ammoniacal silver solution, and consists of a terpene boiling near 175° C. (347° F.) and of liquid anethol boiling at 232° C. (450° F.).

FIG. 157.

Illicium religiosum.

ILL. PARVIFLORUM, Michaux, a native of Florida and Georgia, has yellow flowers and an eight-carpelled fruit, with a sassafras-like flavor; according to R. E. Griffith, the bark may be used as a substitute for cascarilla.

ILL. FLORIDANUM. *Ellis*, grows in Florida and westward to Louisiana, and has purple flowers. The fruit consists of thirteen carpels, has a rather unpleasant terebinthinate taste, and, like the leaves, is poisonous. The plant is known in Alabama as *poison-bay*, and in Louisiana as *stink-bush*.

ILL. GRIFFITHII, *Hooker filius et Thomson*, a native of Eastern Bengal, has a thirteen-carpelled fruit of a bitter and somewhat acrid taste.

ILL. MAJUS, *Hooker filius et Thomson*, grows in the Malayan Peninsula, and has a black-brown fruit consisting of eleven or thirteen carpels, and is of a mace-like taste.

Medical Action and Uses.—Star-anise has the same qualities as the officinal anise, and in the East its seeds and oil are used for similar purposes—viz. as carminative, anodyne, stimulant, and diuretic, and as condiments for vegetable food. Externally, they are applied to allay local pains, such as *colic*, *rheumatism*, *carache*, etc. In Germany they are employed in a similar manner internally, and for the relief of *bronchitis*. The native species, *I. floridanum*, is aromatic in its leaves, bark, and seeds; the bark has been suggested as a substitute for cascarilla, and the seeds for those of anise. The root of *I. parviflorum* is said to resemble that of *sassafras* in its properties. *Illicium* may be administered in the same manner as anise.

I. religiosum has attracted attention within several years on account of its poisonous properties and its close resemblance to star-anise. In 1880 cases of poisoning by the former occurred in Holland, owing to its having been mistaken for the latter (*Am. Jour. Phar.*, Aug. 1881, p. 407); and in the same year in Japan, of five children between two and five years old who had eaten of the fruit, three died, unconscious, in convulsions, and foaming at the mouth. Dr. Langaard, who relates this case (*Virchow's Archiv*, lxxxvi. 222), states that the Japanese use the powder of the plant, every part of which is poisonous, to destroy rats, and also to kill fish, which are not rendered inedible by this mode of death. He refers also to another case in which of six persons who had partaken of *illicium* oil, instead of oil of sesame, one died. 10 Gm. of the oil were given to a large dog. In about 50 minutes the animal moved round in a circle, vomited, had spasmodic movements, with rejection of froth and bile, hard breathing, dilated pupils, diarrhoea, and all the symptoms of an irritant poison, but after about 6 hours recovered. The conclusions drawn by Dr. L. from a series of experiments are substantially the following: 1. The poison of *I. religiosum* resides in all parts of the plant, and by its action on certain centres in the medulla oblongata excites tonic, and also clonic, convulsions, analogous to those caused by picrotoxin, toxiresin, and cicutoxin. 2. In frogs, before the spasms set in, reflex excitability declines in consequence of the irritation of the reflex inhibitory brain-centres. At first the spinal cord is not involved, but the spasms in the last stage of the poisoning are due to its exalted excitability. 3. The respiration is quickened. 4. The pulse is slowed by small doses of the poison. 5. Small doses kill through suspension of respiration, larger doses by arrest of the heart. 6. True star-anise acts in the same manner, but much more feebly than *illicium*.

IMPERATORIA.—MASTERWORT.

Rhizoma (Radix) imperatoriae, P. G.; *Impératoire*, Fr.; *Meisterwurz*, *Kaiserwurz*, G.

The root-stock of *Imperatoria Ostruthium*, *Linné*.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—Masterwort is indigenous to the mountainous regions of Southern and Central Europe, grows 2 or 3 feet (60 or 90 Cm.) high, and has large umbels of many white or reddish flowers. The root-stocks are produced at the termination of thin rhizomes which are about 6 inches (15 Cm.) long.

Description.—The horizontal root-stock is 2 to 4 inches (5–10 Cm.) long, of the thickness of a finger, somewhat conical, and slightly flattened. Externally, it is dark brownish-gray, wrinkled, with warty protuberances or scars, and finely annulate. Internally, it is brownish-white, and exhibits upon the transverse section a thin bark and a large central pith, both containing many brown-yellow resin-cells; the wood-bundles are small, yellowish, and form a loose circle. Masterwort has a strong balsamic odor and an aromatic, pungent, and bitter taste. It has been noticed by Holmes (1877) as an adulteration of *aconite-root*.

Constituents.—Masterwort contains about $\frac{3}{4}$ per cent. of volatile oil, which, according to Hirzel (1849), is a mixture of several hydrates of a hydrocarbon, $C_{10}H_{16}$. Wackenroder (1831) obtained colorless shining crystals of *imperatorin*, $C_{12}H_{12}O_3$, which, in alcoholic

solution only, have a pungent taste. Schlatter (1833) obtained *peucedanin* from the root of *Peucedanum officinale*, *Linné*, which was afterward proved by R. Wagner to be identical with *imperatorin*. Both principles, when boiled with an alcoholic solution of potassa, are resolved into *angelic acid* and *oreoselin*, $C_{14}H_{12}O_4$. The latter body may also be obtained from *athamantin*, $C_{24}H_{30}O_7$, which was discovered by Winckler (1842) in the root of *Athamanta* (*Peucedanum*, *Mench*) *Oreoselinum*, *Linné*. *Athamantin* resembles *imperatorin*, unites with dry hydrochloric acid, and on boiling this compound with alcohol is split into *valerianic acid* and *oreoselon*, $C_{10}H_{10}O_3$, which crystallizes in needles, and on being boiled with water and an acid yields the crystalline *oreoselin*.

Medical Action and Uses.—The acrid and aromatic taste of this plant and its odor, resembling that of *angelica*, depend upon its essential oil, and to the stimulating operation of this oil nearly all the medicinal virtues of the medicine are due. It is but little used at the present day, but it was formerly prescribed in various conditions of local or general debility. Among these were the *typhoid state* of fevers and inflammations, *intermittent fever*, *delirium tremens*, and some forms of *dropsy*, *atonic dyspepsia*, *flatulent colic*, *hysteria*, and *asthma*; and locally it was used as a masticatory to relieve *toothache* and *paralysis* of the tongue or palate and as a stimulant of unhealthy *ulcers*. It may be administered in an infusion made with from 5 to 10 parts of the root and 100 parts of hot water.

INDIGO.—INDIGO.

Indicum, *Pigmentum indicum*.—*Indigo*, Fr., G.

A blue dye-stuff extracted from different species of *Indigofera*. Bentley and Trimen, *Med. Plants*, 72.

Nat. Ord.—*Leguminosæ*, *Papilionaceæ*.

Origin.—The genus consists of herbaceous or suffruticose plants which are indigenous to and cultivated in tropical and subtropical countries. The most important species are *Indigofera tinctoria*, *Linné* (s. *I. indica*, *Lamarch*); *I. Anil*, *Linné*, and *I. argentea*, *Linné* (s. *I. glauca*, *Lamarch*; *I. cœrulea*, *Roxburgh*). The genus *Baptisia* appears to yield a similar coloring matter. Indigo is also obtained from *Isatis tinctoria*, *Linné* (*Nat. Ord.* *Cruciferae*), the *woad*, indigenous to Europe, and from *Polygonum tinctorium*, *Linné* (*Nat. Ord.* *Polygonaceæ*), which is a native of China.

Preparation.—The plants are immersed in water until fermentation has set in, whereby the chromogene is dissolved. When the liquid has assumed a sherry color it is drawn off and briskly stirred, so as to bring it freely into contact with air. As the chromogene becomes oxidized the newly-formed coloring matter, which is insoluble in water, subsides. The supernatant liquid is then decanted, and the deposit heated to boiling to arrest fermentation, after which the precipitate is collected, pressed, and dried. Nearly 1,000,000 pounds of indigo were imported into the United States in 1876, and over 3,000,000 pounds in 1882.

Properties.—Indigo is met with in porous, hard, but brittle lumps or cubical cakes, which are inodorous, tasteless, and of a deep-blue color, assuming a coppery lustre when scratched or rubbed with a hard body; inferior qualities are of a dull hue, with a greenish or grayish tint, dense, firm, and not brittle. It is insoluble in the ordinary solvents, dissolves freely in concentrated sulphuric acid, and when rapidly heated sublimes partly in purple-colored vapors which condense into copper-colored needles. The color of indigo is altered by oxidizing and deoxidizing agents.

Constituents.—Indigo contains variable quantities of inorganic substances; when of good quality it yields about 7 per cent. of ash. It contains the proteid *indigo-gluten*, which is soluble in warm diluted acids, and the coloring principles *indigo-brown*, soluble in caustic alkalies, and *indigo-red* or *indigo-resin*, which is taken up by boiling alcohol

after the indigo has been previously exhausted with dilute acids and alkalies. But the most important principle is *indigo-blue* or *indigotin*, of which good indigo contains between 50 and 60 or 70 per cent., and which is not contained in the plants, but is formed from a colorless syrupy bitterish compound called *indican*, $C_{26}H_{33}NO_{18}$. During the treatment described above indican is split into a saccharine body, *indiglucin*, $C_6H_{10}O_6$, and indigotin, $C_{16}H_{10}N_2O_2$. On mixing 2 or 3 parts of finely-powdered indigo, 6 parts of slaked lime, 4 parts of ferrous sulphate, and 450 parts of boiling water the blue color disappears, and the yellow solution contains *indigo-white*, $C_{16}H_{12}N_2O_2$, which may be obtained as a white crystalline powder on adding the clear solution to an excess of boiled dilute hydrochloric acid with the precaution to avoid all contact with the air; if access of air be permitted during the latter part of this process, indigotin is regenerated and deposited in the form of a deep-blue powder. By oxidation of indigotin with nitric acid, *isatin*, $C_{16}H_{10}N_2O_4$, is obtained, forming yellowish-red shining, bitter prisms which are soluble in alcohol, hot water, and alkalies, and on distillation with potassa yield *aniline*.

Soluble indigo, or *sulphate of indigo*, is prepared by gradually adding 1 part of powdered indigo to 5 parts of Nordhausen sulphuric acid or 8 parts of oil of vitriol, and preventing a rise of temperature by immersing the vessel in cold water. In the course of 2 or 3 days it becomes a dark-blue pasty mass, the solution of which in about 2 parts of water is *liquid blue*. The solution of indigo in sulphuric acid contains two compounds—*sulpho-purpuric acid* or *indigo-purple*, $C_{16}H_9N_2O_2 \cdot HSO_3$, and *sulphindigotic* or *sulphocarmic acid*, $C_{16}H_9N_2O_2(HSO_3)_2$; the first one of these is insoluble in dilute acids, in which the second remains dissolved, and is obtained pure by transferring it from its dilute solution to wool and dissolving it from the latter by means of a weak alkali. Its salts are amorphous; those with potassium and sodium are sold in commerce as *indigo-carmine*, and are usually obtained by adding a potassium or sodium salt to a solution of sulphate of indigo, washing the precipitate with a solution of the same salt, and expressing; the product is soluble in pure water.

Artificial Indigo.—The synthetical preparation of indigo has been the subject of research for a series of years, and was finally accomplished by Prof. Adolf Baeyer (1878) by converting toluol, through a number of intermediate products, into isatin, and finally into indigotin. This elaborate process not promising commercial success, a more direct one, which is now in successful operation, was devised by the same chemist, starting with cinnamic acid prepared from coal-tar. It is converted by nitric acid into *nitro-cinnamic acid*, $C_6H_4(NO_2)C_2H_2COOH$; this with bromine yields *nitrodibrom-cinnamic acid*, $C_6H_4(NO_2)C_2H_2Br_2COOH$, which, by the action of caustic alkali, parts with bromine and hydrogen and leaves *orthonitrophenyl-propionic acid*, $C_6H_4(NO_2)C_2COOH$. On heating this with an alkaline solution of grape-sugar, which acts as a reducing agent, oxygen and carbonic dioxide are eliminated, and indigotin ($C_{16}H_8N_2O$)₂ is produced.

Valuation.—This is based upon determining approximately the amount of indigotin contained in indigo by the process given above, or by adding chlorine ($KClO_3$ and HCl) to finely-powdered indigo until the blue color has been destroyed. The richer it is in indigotin the larger will be the amount of chlorine necessary to effect decolorization.

Adulteration.—Indigo may be adulterated with water, which the better qualities readily absorb; when dried at $100^\circ C.$ ($212^\circ F.$) it should lose not over 6 per cent. in weight. The best qualities of indigo leave from 4 to 8 per cent. of ash when incinerated; a larger percentage indicates admixture of inorganic matter. Guin or starch, if present, forms with hot water a mucilaginous liquid or paste, and if treated with strong sulphuric acid is carbonized, coloring the indigo black. Adulteration with Prussian blue is detected with caustic potassa or soda, which does not alter indigo, but liberates from Prussian blue ferric hydrate, while potassium or sodium ferrocyanide remains in solution.

Pharmaceutical Uses.—Besides its uses in the arts for dyeing, a solution of indigo is employed as a test for determining the presence of nitric acid, chlorine, etc.

Medical Action and Uses.—During the experiments made many years ago with indigo in the treatment of *epilepsy*, it was given in very large doses, and, as a consequence, deranged the digestive organs, causing vomiting and purging, with debility and some nervous disorder. In some instances the urine and sweat acquired a bluish color. There is not the slightest ground for believing that it exhibits curative virtues in epilepsy or in any other disease. Its dose is usually stated to be from 5 to 15 grains and upward.
